The U. S. P. infusion has, in our opinion, been improved. Cinnamon is used solely as a flavoring ingredient, as it has never been present in sufficient quantity to serve any other purpose. When either the tincture or the aromatic itself is used, precipitation is sure to take place. Cinnamon water is unobjectionable. The present process, which is modelled after the formula of L. G. Blakeslee (*Pharm. Era*, 1887, p. 288), yields a preparation which, while not differing essentially in strength from the former official infusion, keeps better and does not deposit to any extent. The addition of 10 per cent. of glycerin would be a still greater improvement. Mr. D. E. Prall (*A. J. P.*, 1878, p. 423) proved that the abundant precipitate in the old infusion was caused by the tincture of cinnamon, and recommended a simple infusion without any aromatic. J. W. England (*A. J. P.*, 1892, 361) prefers to omit cinnamon entirely from the preparation and add ammonia water (90 minims in a pint). Dr. G. L. Humphreys suggests the addition of 8 Gm. of powdered cinnamon to the official ingredients, pouring the boiling water upon the digitalis and cinnamon and macerating until the mixture is cold, then

following the official directions, and finally filtering the infusion through *unwetted* filtering paper. (*West. Drug.*, 1897, 162.)

The U. S. infusion is essentially the same as that employed by Withering. It affords precipitates with ferrous sulphate, lead acetate, tannic acid, and infusion of cinchona. The dose has usually been stated at half a fluidounce (15 C.c.), repeated twice a day under ordinary circumstances, every eight hours in urgent cases, until the system is affected. The proportion of digitalis is scarcely half as great in the British preparation, and the dose is proportionally larger. It will not escape the close observer that the stated dose of digitalis in infusion is much larger than in substance, for which there does not appear to be a good reason, but which accounts for the fact that many physicians assert that they get better results from the infusion than from the digitalis itself. The British Pharmacopœia, though its infusion has only about half the strength of ours, gives its dose as from two to four fluidrachms (7·5–15 C.c.).

INFUSUM ERGOTÆ. Br. Infusion of Ergot.

(ĮN-FŪ'ŞŬM ĒR'GO-TÆ.)

Tisane de Seigle ergoté, *Fr.;* Mutterkornaufguss, *G.*

"Ergot, freshly crushed, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The dose of this infusion is two fluidounces (60 C.c.).

INFUSUM GENTIANÆ COMPOSITUM. Br. Compound Infusion of Gentian.

(ĮN-FŪ'ŞŬM JĔN-TĮ-Ā'NÆ CŌM-PŎŞ'Į-TŬM.)

Tisane de Gentiane composée, *Fr.;* Enzianaufguss, *G.*

"Gentian Root, thinly sliced, ¼ *ounce* (Imperial) or 12·5 grammes; Dried Bitter-Orange Peel, cut small, ¼ *ounce* (Imp.) or 12·5 grammes; Fresh Lemon Peel, cut small, ½ *ounce* (Imp.) or 25 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

"Take of Gentian, in moderately coarse powder, *half a troyounce;* Bitter Orange Peel, in moderately coarse powder, Coriander, in moderately coarse powder, each, *sixty grains;* Alcohol *two fluidounces;* Water *a sufficient quantity.* Mix the Alcohol with fourteen fluidounces of Water, and, having moistened the mixed powders with three fluidrachms of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them first the remainder of the menstruum, and afterwards Water, until the filtered liquid measures a pint." *U. S.* 1870.

It is, in our opinion, unfortunate that this, the most esteemed of all infusions, should not have been reinstated in the U. S. P. 1890 revision. We have inserted the formula of U. S. P. 1870, as it will doubtless continue to be largely prescribed. It should be designated, however, as U. S. P. 1870. It has been the custom with some physicians to prescribe a concentrated infusion made with one-fourth the quantity of menstruum directed by the formula of U. S. P. 1870. This permits the use of a valuable tonic with the presence of but a trifling amount of alcohol. This concentrated preparation keeps well, and it may be diluted with the right quantity of the proper menstruum by the pharmacist to make the infusion of U. S. P. 1870. The use of the alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very apt to spoil. It has, however, been abandoned by the British Pharmacopœia, and lemon peel substituted: this is a very doubtful improvement. The dose is a fluidounce (30 C.c.), repeated three or four times a day.

INFUSUM KRAMERIÆ. Br. Infusion of Krameria.

(ĮN-FŪ'ŞŬM KRĄ-MĒ'RĮ-Æ.)

Infusion of Rhatany; Tisane de Ratanhia, *Fr.;* Ratanha-Aufguss, *G.*

"Krameria Root, bruised, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The infusion of rhatany is undoubtedly most efficient when prepared from the root in a state of moderately coarse powder by the mode of percolation with cold water, as directed in the U. S. process of 1870. Dose of the infusion, from one to two fluidounces (30–60 C.c.).

INFUSUM LUPULI. Br. Infusion of Hops.

(ĮN-FŪ'ŞŬM LŪ'PŬ-LĪ.)

Infusum Humuli, *U. S.* 1870; Tisane de Houblon, *Fr.;* Hopfenaufguss, *G.*

"Hops, freshly broken, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The infusion of hops of the U. S. P. 1870 was made exactly like the above, except that the strength was half a troyounce to a pint. The dose of the British infusion is from one to two fluidounces (30–60 C.c.).

INFUSUM PRUNI VIRGINIANÆ. U. S. Infusion of Wild Cherry.

(ĮN-FŪ'ŞŬM PRŪ'NĪ VĬR-ĢĬN-Į-Ā'NÆ.)

Tisane d'Ecorce de Cerisier sauvage, *Fr.;* Wildkirschen-Thee, *G.*

"Wild Cherry, in No. 20 powder, *forty grammes* [or 1 ounce av., 180 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 391 minims]. Moisten the powder with *sixty cubic centimeters* [or 2 fluidounces, 14 minims] of Water, and macerate for one hour; then pack it firmly in a conical glass percolator, and gradually pour Water upon it until the Infusion measures *one thousand cubic centimeters* [or 33 fluidounces, 391 minims]." *U. S.*

This is a peculiarly suitable object for official direction, as, in consequence of the volatile nature of one of its active ingredients, and for another reason (see *Prunus Virginiana*), it is better prepared with cold water than in the ordinary mode. The infusion of wild cherry bark is one of the preparations to which the process of percolation or displacement is well adapted. In this way the virtues of the bark can be more rapidly and thoroughly exhausted than by maceration alone. In order to allow time for the reaction necessary to the production of the hydrocyanic acid, an hour's preliminary maceration is directed, which might perhaps be advantageously somewhat lengthened. If kept in a warm place this preparation undergoes a rapid alteration, and even under the best of circumstances it is unstable. According to the experiments of Mr. J. B. Moore (*A. J. P.*, 1873, p. 242), confirmed by our own experience, the addition of two fluidounces of glycerin to the pint of menstruum is of great advantage in delaying the change. When properly made, infusion of wild cherry bark is beautifully transparent, has the color of Madeira wine, and the agreeable bitterness and peculiar flavor of the bark. The dose is from two to three fluidounces (60–90 C.c.) from three to six times a day.

INFUSUM QUASSIÆ. Br. Infusion of Quassia.

(ĮN-FŪ'ŞŬM QUÄS'SĮ-Æ.)

Tisane de Quassie, *Fr.;* Quassia-Aufguss, *G.*

"Quassia Wood, finely rasped, 88 *grains* (Imperial) or 10 grammes; Distilled Water, cold, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

Boiling water may be employed when it is desirable to obtain the preparation quickly; but cold water affords a clearer infusion. The fifteen minutes maceration directed in the British Pharmacopœia, considering that cold water is used, appears to us to be too short for the exhaustion of the wood. The dose is two fluidounces (60 C.c.) three or four times a day.

INFUSUM RHEI. Br. Infusion of Rhubarb.

(ĮN-FŪ'ŞŬM RHĒ'Ī.)

Tisane de Rhubarbe, *Fr.;* Rhabarber-Aufguss, *G.*

"Rhubarb Root, in thin slices, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

In order that the rhubarb may be exhausted, it should be digested with the water near the fire, at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel-seed, or nutmeg, which improves the taste of the infusion and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connection with the rhubarb.

This infusion may be given as a gentle laxative, in the dose of from one to two fluidounces (30–60 C.c.) every three or four hours till it operates. It is occasionally used as a vehicle for tonic, antacid, or more active cathartic medicines. The stronger acids and most metallic solutions are incompatible with it.

INFUSUM ROSÆ ACIDUM. Br. Acid Infusion of Roses.

(ĮN-FŪ'ŞŬM RŌ'ŞÆ AÇ'Į-DŬM.)

Infusum Rosæ Compositum, *U. S.* 1870; Compound Infusion of Rose; Acid Infusion of Rose; Tisane de Rose composée, *Fr.;* Saurer Rosenaufguss, *G.*

"Red-Rose Petals, dried and broken, ½ *ounce* (Imperial), or 25 grammes; Diluted Sulphuric Acid, 2 *fl. drachms* (Imp. meas.) or 12·5 cubic centimetres; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Add the Diluted Sulphuric Acid to the Distilled Water; infuse the Red-Rose Petals in the mixture in a covered vessel for fifteen minutes; strain." *Br.*

The formula of the U. S. P. 1870 is preferable to that of the Br. Pharm. on account of the presence of sugar. It is unfortunate, in our opinion, that this elegant infusion was not reintroduced at the last revision of the U. S. Pharmacopœia. We append the formula of the U. S. P. 1870: "Take of Red Rose [dried petals] *half a troyounce;* Diluted Sulphuric Acid *three fluidrachms;* Sugar [refined], in coarse powder, *a troyounce and a half;* Boiling Water *two pints and a half.* Pour the Water upon the Rose in a covered glass or porcelain vessel; add the Acid, and macerate for half an hour. Lastly, dissolve the Sugar in the liquid, and strain." *U. S.*

The red rose serves little other purpose than to impart a fine red color and a slight astringent flavor to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. According to Mr. J. B. Barnes, one part of glycerin added to eight or nine parts of infusion of rose increases greatly its brightness and transparency. It is refrigerant and astringent, and affords a useful and not unpleasant drink in hemorrhages and colliquative sweats. It is much used by British practitioners as a vehicle for saline medicines, particularly magnesium sulphate, the taste of which it serves to cover. It is also employed as a gargle, usually in connection with acids, nitre, alum, or tincture of Cayenne pepper. The dose is two fluidounces (60 C.c.).

INFUSUM SCOPARII. Br. Infusion of Broom.

(ĮN-FŪ'ŞŬM SCǪ-PĀ'RĮ-Ī.)

"Broom Tops, dried and bruised, 2 *ounces* (Imperial) or 100 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

This preparation has been introduced in place of the Decoction of Broom of the British Pharmacopœia of 1885. Water thoroughly extracts the virtues of broom, and the quantity of water in each dose aids the diuretic action. Dose, from one to two fluidounces (30–60 C.c.).

INFUSUM SENEGÆ. Br. Infusion of Senega.

(ĮN-FŪ'ŞŬM SĒN'Ę-ÇÆ.)

Tisane de Polygale de Virginie, *Fr.;* Senega-Aufguss, *G.*

"Senega Root, in No. 10 powder, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for half an hour; strain." *Br.*

The dose of the preparation is one fluidounce (30 C.c.).

INFUSUM SENNÆ. Br. Infusion of Senna.

(ĮN-FŪ'ŞŬM SĒN'NÆ.)

Senna Tea; Tisane de Séné, *Fr.;* Senna-Aufguss, *G.*

"Senna, 2 *ounces* (Imperial) or 100 grammes; Ginger, sliced, 55 *grains* (Imp.) or 6·25 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

"Take of Senna *a troyounce;* Coriander, bruised, *sixty grains;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.* 1870.

We prefer the coriander of the U. S. P. 1870 to the ginger of the British. The strength of the British preparation has been increased in the present edition of the Br. Pharm., and is now nearly one and a half times as great as that of the U. S. infusion. The infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency: it should, therefore, not be made in large quantities. It is customary to prescribe with it manna and some one of the saline cathartics, which increase its efficacy and render it less painful in its operation. (See *Infusum Sennæ Compositum.*) The dose of the infusion is

about two fluidounces (60 C.c.). The cold infusion, especially if made by percolation from the coarsely powdered leaves, while probably not inferior in strength to that prepared with boiling water, is said to be less unpleasant to the taste.

INFUSUM SENNÆ COMPOSITUM. U. S. Compound Infusion of Senna.

[Black Draught.]

(ĮN-FŪ'ZŬM SĔN'NÆ CŌM-PŎS'Į-TŬM.)

Tisane de Séné composée, *Fr.;* Senna-Aufguss, *G.*

"Senna, *sixty grammes* [or 2 ounces av., 51 grains]; Manna, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Magnesium Sulphate, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Fennel, bruised, *twenty grammes* [or 309 grains]; Boiling Water, *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims]; Cold Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Upon the Senna and Fennel, contained in a suitable vessel, pour the Boiling Water, and macerate until the mixture is cold. Then strain with expression, dissolve in the infusion the Magnesium Sulphate and Manna, and again strain. Lastly, add enough Cold Water through the strainer containing the Senna and Fennel to make the Infusion measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

This preparation is the Black Draught of European pharmacy, and it is an excellent form of administering these cathartics in a liquid condition. The dose is about four fluidounces (118 C.c.).

INFUSUM SERPENTARIÆ. Br. Infusion of Serpentary.

(ĮN-FŪ'ZŬM SĔR-PĘN-TĀ'RĮ-Æ.)

Tisane de Serpentaire, *Fr.;* Schlangenwurzel-Aufguss, *G.*

"Serpentary Rhizome, in No. 10 powder, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The dose of this preparation is one fluidounce (30 C.c.) every two hours in low forms of fever, but less frequently in chronic affections.

INFUSUM UVÆ URSI. Br. Infusion of Bearberry.

(ĮN-FŪ'ZŬM Ū'VÆ ŬR'SĪ.)

Tisane d'Uva Ursi, *Fr.;* Bärentraubenblätter-Aufguss, *G.*

"Bearberry Leaves, bruised, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The dose is from one to two fluidounces (30–60 C.c.) three or four times a day.

INJECTIONES HYPODERMICÆ. Hypodermic Injections.

Under this head are classed preparations which are recognized in the British Pharmacopœia for hypodermic application. These preparations are really of very little value, on account of their proneness to undergo decomposition, and are greatly inferior to the *hypodermic tablets* of various strengths which are now supplied by manufacturing pharmacists,—the size of the tablets not varying with the strength, because it is always necessary to use so much diluent in order to make the tablet of sufficient size to handle conveniently. The tablets most used contain morphine, morphine and atropine, atropine, strychnine, pilocarpine, cocaine, hyoscyamine, eserine, hyoscine, or caffeine; each should be readily soluble in fifteen minims of water. These tablets should be made official, since their convenience, permanence, and accuracy in weight have caused them to come into universal use. The selection of the diluent is an important question: very finely powdered cane sugar has been employed, but is apt to produce local irritation and even abscesses. Sodium chloride has also been recommended; but the best diluent seems to be dried neutral sodium sulphate.

INJECTIO APOMORPHINÆ HYPODERMICA. Br. Hypodermic Injection of Apomorphine.

(ĮN-JĔC'TĮ-Ō ĂP-Ǫ-MŌR-PHĪ'NÆ HĬ-PǪ-DĔR'MĮ-CĄ—įn-jĕk'shę-ō.)

"Apomorphine Hydrochloride, 1 *grain* (Imperial) or 0·1 gramme; Diluted Hydrochloric Acid, 1 *minim* (Imp. meas.) or 0·1 cubic centimetre; Distilled Water, 110 *minims* (Imp. meas.)

or 10 cubic centimetres or a sufficient quantity. Boil the Distilled Water for a few minutes; cool; add the Diluted Hydrochloric Acid; dissolve the Apomorphine Hydrochloride in the resulting liquid; add, if necessary, sufficient recently boiled and cooled Distilled Water to produce *one hundred and ten minims* (Imp. meas.) or ten cubic centimetres of the Injection. This Injection should be recently prepared. 110 minims contain 1 grain of Apomorphine Hydrochloride; 100 cubic centimetres contain 1 gramme." *Br.* The dose, by subcutaneous injection, is from two to eight minims (0·123–0·49 C.c.).

INJECTIO COCAINÆ HYPODERMICA. Br. Hypodermic Injection of Cocaine.

(ĮN-JĔC'TĮ-Ō CŌ-CĄ-Ī'NÆ HĪ-PŌ-DĔR'MĮ-CĄ.)

"Cocaine Hydrochloride, 33 *grains* (Imperial) or 1 gramme; Salicylic Acid, ½ *grain* (Imp.) or 0·015 gramme; Distilled Water, 6 *fl. drachms* (Imp. meas.) or 10 cubic centimetres or a sufficient quantity. Boil the Distilled Water; add the Salicylic Acid; dissolve the Cocaine Hydrochloride in the solution when cool; add, if necessary, sufficient recently boiled and cooled Distilled Water to produce *six fluid drachms* (Imp. meas.) or ten cubic centimetres of the Injection. 110 minims contain about 10 grains of Cocaine Hydrochloride; 100 cubic centimetres contain 10 grammes." *Br.* Dose, by subcutaneous injection, from two to five minims (0·123–0·3 C.c.).

INJECTIO ERGOTÆ HYPODERMICA. Br. Hypodermic Injection of Ergot.

(ĮN-JĔC'TĮ-Ō ĔR'GŌ-TÆ HĪ-PŌ-DĔR'MĮ-CA.)

Hypodermic Injection of Ergotin.

"Extract of Ergot, 100 *grains* (Imperial) or 10 grammes; Phenol, 3 *grains* (Imp.) or 0·3 gramme; Distilled Water, 220 *minims* (Imp. meas.) or 20 cubic centimetres or a sufficient quantity. Mix the Phenol with the Distilled Water; boil for a few minutes; cool; add the Extract of Ergot, and, if necessary, sufficient recently boiled and cooled Distilled Water to produce *three hundred and thirty minims* (Imp. meas.) or thirty cubic centimetres of the Injection. This Injection should be recently prepared. 110 minims contain about 33 grains of Extract of Ergot; 100 cubic centimeters contain about 33 grammes." *Br.* Dose, by subcutaneous injection, from three to ten minims (0·18–0·61 C.c.).*

INJECTIO MORPHINÆ HYPODERMICA. Br. Hypodermic Injection of Morphine.

(ĮN-JĔC'TĮ-Ō MÖR-PHĪ'NÆ HĪ-PŌ-DĔR'MĮ-CĄ.)

"Morphine Tartrate, 50 *grains* (Imperial) or 5 grammes; Distilled Water, *a sufficient quantity*. Dissolve the Morphine Tartrate in sufficient recently boiled and cooled Distilled Water to produce *eleven hundred minims* (Imp. meas.) or one hundred cubic centimetres of the Injection." *Br.*

This solution is made from morphine tartrate in place of the morphine acetate formerly used; this is a great improvement, as the acetate is the most unstable of all morphine salts. The morphine strength of this Injection is slightly less than one-half that of the Hypodermic Injection of Morphine of the British Pharmacopœia of 1885. 110 minims contain 5 grains of Morphine Tartrate; 100 cubic centimetres contain 5 grammes. Dose, by subcutaneous injection, from two to five minims (0·123–0·3 C.c.).

INULA. U. S. Inula. [Elecampane.]

(ĪN'Ū-LĄ.)

"The root of Inula Helenium, Linné (nat. ord. Compositæ)." *U. S.*

Aunée, *Fr.;* Alantwurzel, *G.;* Enula Campana, *It., Sp.*

About ninety species of this genus are recognized and distributed in Europe, Asia, and Africa, one species being naturalized in North America.

Inula helenium. L. *Sp. Pl.* (1753), ed. 1, 881; Willd. *Sp. Plant.* iii. 2089; Woodv. *Med. Bot.* 64, t. 26. Elecampane has a perennial root, and an annual stem, which is round, fur-

* *Injectio Ergotini Hypodermica.* Br. 1885. *Hypodermic Injection of Ergotin.* "Take of Ergotin *one hundred grains;* Camphor Water *two hundred fluidgrains* (or 3 fluidrachms). Dissolve by stirring them together. The solution should be made as required for use." The dose, by subcutaneous injection, is from three to ten minims (0·18–0·61 C.c.).

rowed, villous, leafy, from three to six feet high, and branched near the top. The leaves are large, ovate, serrate, crowded with reticular veins, smooth and deep green upon the upper surface, downy on the under, and furnished with a fleshy midrib. Those which spring directly from the root are petiolate, those from the stem sessile and clasping. The flower heads are large, of a golden-yellow color, and stand singly at the ends of the stem and branches. The involucre consists of several rows of imbricated ovate scales. The ray florets are numerous, spreading, linear, and tridentate at the apex. The achenes are striated, quadrangular, and furnished with a simple somewhat chaffy pappus. This large and handsome plant is a native of Europe, where it is also cultivated for medical use. It has been introduced into our gardens, and has become naturalized in some parts of the country, growing in low meadows, and on the roadsides, from Canada and Minnesota southward to North Carolina and Missouri. It flowers in July and August. The roots, which are the official part, should be dug up in autumn, and in their second year. When older they are often stringy and woody.

The fresh root of elecampane is very thick and branched, having whitish cylindrical ramifications, furnished with thread-like fibres. It is externally brown, internally whitish and fleshy; and the transverse sections present radiating lines. The dried root is "in transverse, concave slices or longitudinal sections, with overlapping bark, externally wrinkled and brown; flexible in damp weather; when dry, breaking with a short fracture; internally grayish, fleshy, slightly radiate, and dotted with numerous shining, yellowish-brown resin-cells; free from starch; odor peculiar, aromatic; taste bitter and pungent." *U. S.* Its medical virtues are extracted by alcohol and water, the former becoming most strongly impregnated with its bitterness and pungency. A peculiar principle, resembling starch, was discovered in elecampane by Valentine Rose, of Berlin, in 1804, who named it *alantin;* but the title *inulin*, proposed by Dr. Thomson, has been generally adopted. It differs from starch in being deposited unchanged from its solution in boiling water when the liquor cools, and in giving a yellowish instead of a blue color with iodine. It has been found in the roots of several other plants. It may be obtained white and pure by precipitating a concentrated decoction with twice its volume of alcohol, dissolving the precipitate in a little distilled water, treating the solution with purified animal charcoal, and again precipitating with alcohol. (*A. J. P.*, xxxi. 69.) It readily dissolves in about three parts of boiling water; the lævogyre solution is perfectly clear and fluid, not paste-like, but on cooling deposits nearly all the inulin. Its formula, according to Kiliani (Tollens, *Handbuch der Kohlenhydrate*, 1888, p. 202), is $3C_{12}H_{20}O_{10} + H_2O$. On prolonged heating with water, more rapidly under the influence of dilute acids, it is changed into *levulose* and reduces Fehling's solution. As in the case of starch, intermediate products can be obtained before it is completely changed into reducing sugar. Dragendorff obtained by heating with water for ten hours *metinulin*, and by heating for forty to fifty hours *levulin*, an optically inactive amorphous substance easily changing into *levulose*. Tanret, who has since investigated inulin (*Journ. de Pharm. et de Chim.* 27, 449), confirms Kiliani's formula as given above. He finds associated with inulin two closely related principles: *pseudo-inulin* and *inulenin*. The first of these, to which the formula $(C_6H_{10}O_5)_{16}H_2O$ is given, forms irregular granules, very soluble in water and weak alcohol while hot, but only slightly soluble in cold water, and insoluble in cold alcohol; the second is given the formula $(C_6H_{10}O_5)_{10}.2H_2O$, and forms microscopical needles slightly soluble in cold water and weak alcohol. The amount of inulin varies according to the season, but is most abundant in autumn. Dragendorff obtained from the root in October not less than 44 per cent., but in spring only 19 per cent. A crystallizable substance was long since noticed to collect in the head of the receiver when the elecampane root is submitted to distillation with water. Similar crystals may also be observed after carefully heating a thin slice of the root, and are even found as a natural efflorescence on the surface of a root that has been long kept. They can be extracted from the root by means of alcohol, and precipitated with water. Kallen (*Deutsch. Chem. Ges.*, 1873, 1876) has found that these crystals consist chiefly of the anhydride, $C_{15}H_{20}O_2$, of *alantic acid*, melting at 66° C., and that what was formerly known as *helenin* was a mixture of these with a liquid, *alantol*, $C_{10}H_{16}O$, boiling at 200° C., the true *helenin** and

* Dr. Korab (*London Lancet*, vol. i., 1885, p. 672) states that helenin is a powerful antiseptic and bactericide, one part in ten thousand of urine being sufficient to arrest putrefaction, and a few drops of a solution of this strength immediately killing the ordinary bacterial organisms, including the tubercle-bacillus. He lauds it as antiseptic in surgery, and has given it with alleged success internally in doses of one-third to one grain in tubercular, infantile, and catarrhal diarrhœas. It is also stated by Dr. J. B. Obiol (*Lancet*, April, 1886) to be an efficient local remedy in the treatment of diphtheria. Every four hours the false membrane is to be dusted over with powdered camphor, and then painted with a two-per-cent. solution of helenin in oil of sweet almond. It is affirmed that when the treatment was commenced on the first day of the patches the cure followed in twenty-four hours. The helenin was also given internally. Dose, one and a half grains to children six years of age.

alant camphor. The crystals of *helenin*, C_6H_8O, have a bitterish taste, but no odor, and melt at 110° C. The camphor melts at 64° C., and in taste and smell is suggestive of peppermint.

Medical Properties and Uses. Elecampane is tonic and gently stimulant, and has been supposed to possess diaphoretic, diuretic, expectorant, and emmenagogue properties. By the ancients it was much employed, especially in the complaints peculiar to females; and it is still occasionally resorted to in *amenorrhœa*. In this country it is chiefly used in chronic diseases of the lungs, and is sometimes beneficial when the affection of the chest is attended with weakness of the digestive organs or with general debility. From a belief in its deobstruent and diuretic virtues, it was formerly prescribed in chronic engorgements of the abdominal viscera, and the *dropsy* to which they so often give rise. It has also been highly recommended both as an internal and an external remedy in *tetter*, *psora*, and other diseases of the skin. The usual modes of administration are in powder and in decoction. The dose of the powder is from twenty grains to a drachm (1·3–3·9 Gm.). The decoction may be prepared by boiling half an ounce of the root in a pint of water: dose, from one to two fluidounces (30–60 C.c.).

IODOFORMUM. U. S., Br. Iodoform.

CHI_3; 392·56. (Ī-Ō-DŌ-FÓR'MŬM.) **CHI_3; 392·8.**

"Iodoform should be kept in well-stoppered bottles, in a cool and dark place." *U. S.* "Iodoform, or tri-iodomethane, CHI_3, is a product of the action of iodine on ethylic alcohol in the presence of solution of potassium carbonate." *Br.*

Iodoformum, *P. G.;* Iodoforme, *Fr.;* Iodoform, *G.*

This compound, discovered by Sérullas in 1822, was introduced as a remedy, about the year 1837, by Dr. R. M. Glover, of London, and M. Bouchardat, of Paris, and was first adopted as official in the U. S. Pharmacopœia of 1870.

Preparation. Cornélis and Gille published a process in *Journ. de Pharm.*, 1852, p. 196. (See U. S. D., 14th ed., p. 511.) Wittstein's process is an improvement on this. Take two parts of potassium carbonate, two of iodine, one of 95-per-cent. alcohol, and five of water. mix them in a retort, and heat the mixture, by means of a water-bath, until perfectly colorless; then, after the cooling of the liquid, pour it into a suitable vessel, and allow it to settle. The yellow scaly mass deposited is collected on a filter, washed thoroughly with water, and dried between folds of bibulous paper. As iodoform is very volatile, it must be prepared in closed vessels. The liquid remaining after the deposition of iodoform contains potassium iodate and iodide, which may be decomposed with renewed formation of iodoform by adding potassium dichromate 2 to 3 parts, and hydrochloric acid 16 to 24 parts; this liberates iodine. 32 parts of sodium carbonate, 6 parts of iodine, and 16 parts of alcohol are now added, the liquid is again poured off from the iodoform produced, and the operation again repeated if necessary. The formation of the iodoform is represented by the following equation: $C_2H_5.OH + 4I_2 + 3K_2CO_3 = CHI_3 + CHKO_2 + 5KI + 2H_2O + 3CO_2$. Other products, such as potassium iodate, are, however, formed. Mr. G. R. Bell (*N. R.*, March, 1882) has practically tried nearly all the processes for the preparation of iodoform, and recommends Filhol's, which is as follows. Put into a long-necked matrass or flask which is supplied with a perforated cork and long supply-tube a solution of 200 parts of crystallized sodium carbonate and 1000 parts of distilled water, and add 100 parts of alcohol, heat in a water-bath from 60° to 71·1° C. (140° to 160° F.), then gradually add 100 parts of iodine, about ten parts at a time. When the liquid has become colorless, remove the flask from the water-bath, and allow it to cool three or four hours, then pour out on a filter; return the filtrate to the flask, add 200 parts of sodium carbonate, 100 parts of alcohol, heat to 71·1° C. (160° F.), and pass a slow current of chlorine gas through the mixture as long as iodine is separated, continuing until the brown liquid is again decolorized. A small excess of chlorine is of no consequence (Hager states that for every 100 parts of iodine it requires the chlorine which can be evolved from about 200 parts of hydrochloric acid by means of manganese dioxide). Let the flask stand twenty-four hours, then throw the contents on a filter and examine the filtrate with chlorine water to see whether it still contains an appreciable amount of iodine compounds, then if necessary subject the filtrate to a second treatment of chlorine gas, adding previously only 20 parts of sodium carbonate and 10 parts of alcohol. Collect the iodoform after twenty-four hours. The filtrate may be concentrated and decomposed by excess of nitric acid, according to the method recommended in Bouchardat's process. The collected crystals of iodoform are now well washed with the smallest quantity of cold distilled water, spread out on bibulous paper, and dried in the open air.

Sulliot and Raynaud have devised a process for making iodoform from kelp ash. (*Bull.*

Soc. Chim., 1889, 3.) S. R. Boyce (*Proc. A. P. A.*, 1890, 220) details a process which is essentially that of Sulliot and Raynaud. The advantages claimed for this method are that 98 per cent. of the iodine used is converted into iodoform, and the use of the nitric acid in Filhol's process is obviated. Solution of chlorinated soda is added by drops to a solution of fifty grammes of potassium iodide, five grammes of caustic soda, and forty grammes of acetone in one liter of water. The iodoform, which crystallizes out, should be protected from the light.

The fact, noticed by Lieben in 1870, that many other compounds besides ethyl alcohol yield iodoform when treated with iodine and alkali, led Krämer (*Ber. Chem. Ges.*, 1880, p. 1000) to propose the iodoform formation as an exact quantitative test for the presence of acetone in methyl alcohol. This "iodoform test" is now used in testing the purity of methyl alcohol for use in the manufacture of aniline dye colors, as well as the purity of acetone itself. (See article *Acetone*, PART II.) Heinrich Spindler proposes to make iodoform from the chlorides, bromides, or chloro-bromides of the paraffin series by reaction with an inorganic iodide: thus, if chloroform and *anhydrous* calcium iodide are heated to 120° C. iodoform is produced. (*Amer. Drug.*, 1886, p. 67.) F. Günther recommends mixing alcohol containing 25 per cent. of aldehyde with ten times its weight of solution of soda, adding the iodine, and passing a current of carbonic acid gas through the mixture. (*Archiv d. Pharm.*, 1887, p. 373.)

Properties. It is in the form of "small, lemon-yellow, lustrous crystals of the hexagonal system, having a peculiar, very penetrating and persistent odor somewhat resembling that of saffron and iodine, and an unpleasant slightly sweetish and iodine-like taste. Specific gravity, 2·000 at 15° C. (59° F.) Very slightly soluble in water, to which it, however, imparts its odor and taste. Soluble in about 52 parts of alcohol at 15° C. (59° F.), in about 12 parts of boiling alcohol, and in 5·2 parts of ether. Very soluble in chloroform, benzin, and fixed and volatile oils. Iodoform is slightly volatile even at ordinary temperatures, and in boiling water distils slowly over with its vapor. At about 115° C. (239° F.) it melts to a brown liquid, and at a higher temperature emits vapors of iodine, leaving behind a carbonaceous mass which, upon full combustion, should be completely dissipated (absence of *fixed impurities*). On digesting about 0·1 Gm. of Iodoform with 5 C.c. of a 5-per-cent. solution of potassium hydrate in alcohol, and then slightly supersaturating with diluted nitric acid, the liquid will be rendered blue by starch test-solution. The solutions in neutral solvents are neutral to litmus paper. If 2 Gm. of Iodoform be thoroughly shaken with 10 C.c. of water, the filtrate should be colorless and free from bitter taste (absence of *soluble yellow coloring matter*, *picric acid*, etc.), should not affect the color of litmus paper (absence of *free acids*), and should not be rendered more than faintly opalescent by silver nitrate test-solution (absence of *soluble iodides*)." *U. S.* "Very slightly soluble in cold *water*, soluble in 80 parts of cold or 10 parts of boiling *alcohol* (90 per cent.), in 5 parts of cold *ether*, soluble also in *chloroform*, *carbon bisulphide*, or fixed and volatile oils, and, sparingly, in *benzol*; the solutions do not affect *litmus*. When heated it first melts to a brown liquid, then gives off brown and violet vapors, leaving a black residue which entirely disappears on continued incineration. When warmed with an alcoholic solution of *potassium hydroxide* and the resulting liquid acidulated with *nitric acid*, iodine is liberated, the mixture becoming brown, and, when cold, blue on the addition of *mucilage of starch*. *Water* with which Iodoform has been shaken should be colorless and not bitter (absence of soluble yellow coloring matters, picric acid, etc.), and should not yield any reaction with the tests for iodides." *Br.* Iodoform is a volatile substance, soft to the touch, and totally devoid of corrosive properties. With potassa in solution, it is decomposed, yielding potassium formate and iodide. Hence these two principles are incompatible in prescriptions. Iodoform is sometimes met with in commerce adulterated with water; Vulpius (*Pharm. Central.*, 1894) on examination detected 13 per cent. in one specimen.

Medical Properties and Uses. M. Maitre, who has studied the physiological effects of iodoform on men, states that from a dose of 30 or 40 centigrammes (about 5 or 6 grains) no effects are observed except a slight increase of appetite. Two hours after it has been taken the presence of iodine can be detected in the urine and the saliva, and nearly three days elapse before the whole is eliminated. (See also Höyges, *Journ. de Pharm.*, Juillet, 1867.) It passes off also with the lacteal secretion. Given to dogs in much larger doses, several grammes for example, it produces narcotic effects; and two stages in its operation have been noticed: the first is marked with more or less prostration, with symptoms of intoxication, the animal tottering, inclining to one side with the head falling, with loss of appetite, but without vomiting. The next day, unless a very large dose has been given, complete recovery takes place. A still larger dose induces the second stage, characterized by a remarkably intense excitation, with

anxious breathing, strong and short pulse, a true opisthotonos, sometimes very striking, and convulsive movements of the paws, especially the hinder. After death fatty degeneration of the heart, liver, and kidneys may be found. (*A. Höyges.*) The very free use of iodoform in Germany as an antiseptic dressing to wounds, ulcers, etc., has led to many cases of poisoning. In the most characteristic and severe cases the phenomena of iodoform-poisoning resemble somewhat those of meningitis: they are headache, somnolence deepening into stupor, contracted, motionless pupils, abnormal quiet or restlessness ending in active delirium, with, however, a normal temperature and an exceedingly rapid pulse.* In cases of this character death almost always follows, although the symptoms may have developed abruptly and the dressing have been removed at once. In other cases the principal symptoms are general malaise and depression, faintness, headache, loss of appetite, and a persistent iodoform taste in the mouth. In some cases there is a slight temporary increase of temperature. Mental depression or excitement is especially noticed. Finally the pulse becomes accelerated, soft, and feeble; in some cases the pulse is very rapid,—from 150 to 180,—while the temperature remains normal, or only slightly elevated. It is asserted by Samter and Retzlaff (*T. G.*, 1889) that potassium bromide is an antidote in poisoning with iodoform, its antidotal powers being due to the fact that it exceeds all other salts in its power of dissolving iodine compounds.

Iodoform, though containing 29 parts in 30 of its weight of iodine, is not locally irritant, but anæsthetic and antiseptic. It is said, when employed as a suppository, to produce unconsciousness of the act of defecation. In the form of vapor, it possesses anæsthetic properties, but inferior to those of chloroform. On account of its large proportion of iodine, it was supposed to be capable of replacing that element and the iodides as a remedy, with the advantages of being non-irritant, and of having an organic nature, qualities which favor its absorption and assimilation. The principal diseases in which it has been tried are *goitre*, *rickets*, *scrofula*, *phthisis*, *syphilis*, and *glandular tumors*. It may be given in doses of from one to three grains, three or four times a day, in pill form; but it has not met the expectation of its early advocates, and is not much used internally. The chief value of iodoform in practical medicine is as an external application. It has long been used in cases of painful *ulcers*, especially when of syphilitic origin, but has been found to act almost equally well in indolent leg ulcers and other non-specific abrasions, and will even produce marked relief in open cancers.† Within the last few years it has been freely employed as an antiseptic dressing to wounds, and the testimony from surgeons is so strong that it is difficult to avoid believing that it is one of the most certain remedies of the class. The good results which have been achieved have led to a series of studies of its action upon septic organisms, with results which are apparently at variance with practical surgical teachings,‡ and which seem to prove that iodoform itself has little power as a bactericide. When, however, it is brought in contact with the living surface of a wound it undergoes a slow chemical change, resulting in the liberation of iodine, which element has a distinct influence upon the development of septic organisms. Moreover, iodoform appears to have a specific influence upon human tissue, by which it prevents the formation of purulent or serous exudations, and greatly diminishes the soil in which the bacteria develop. The local application of iodoform in surgical tuberculosis has received the highest commendation from numerous surgeons. In the treatment of tubercular *abscesses*, in tubercular *empyema*, in tubercular joints, in non-suppurating tuberculous glands, and even in tuberculous *peritonitis*, numerous cures have been claimed. That iodoform has a specific influence upon the tubercular organism would seem to follow from the experiments of Gosselin, of Caen, who found that guinea-pigs saturated with iodoform are incapable of contracting tuberculosis. Lawrence Flick recommends inunctions of iodoform or of *europhen* as of the greatest service in the treatment of early *phthisis*. Of the following formula a tablespoonful is to be rubbed thoroughly into the inside of the thigh or into the armpit before retiring at night: europhen or iodoform, 1 drachm; oil of rose, 1 drop; oil of anise, 1 fluidrachm; olive oil, 2½ fluidounces.

* *Diagnostic Sign of Iodic Poisoning.* M. Burlureaux affirms that if a piece of silver be placed in the mouth of a person suffering from iodoform poisoning, immediately the taste of garlic will be perceived; and if some of the saliva be mixed with calomel, a canary-yellow precipitate of mercurial iodide will be obtained. The most that such a test can accomplish is to show that the patient is under the influence of some compound of iodine.

† *Iodoform in Burns.* At a discussion of the International Congress of Dermatology, in 1889, the conclusion was reached that the best treatment of *burns* in the beginning is to cut the bullæ, wash the part with a very weak solution of salt, and then dress with iodoform gauze or a pomade of iodoform, and cover with oil-silk. In the later stages, after the separation of the eschars, according to Hebra, iodoform retards cicatrization, whilst a one- or two-per-cent. solution of resorcin hastens epithelium formation.

‡ For a more elaborate discussion of these investigations, the reader is referred to Dr. H. C. Wood's *Treatise on Therapeutics*, 7th edition.

The manner of application varies with different surgeons. Verneuil, who has had an enormous experience, prefers in the treatment of abscesses and of tuberculous glands, and in most other cases, the injection of a 5-per-cent. ether solution. Others prefer glycerin as a vehicle, especially in empyema cases; whilst others, especially in peritonitis, dust the dry powder over the surface which has been laid open. In uterine affections, vaginal suppositories made by incorporating 5·5 grains of iodoform with 2·5 drachms of cacao butter have been largely used, and similar rectal suppositories have been employed with asserted advantage in enlargements of the prostate gland and in fissures of the anus. In surgical dressings with iodoform the powder is usually sprinkled freely upon the wounds and secured in place by a dry dressing. *Iodoform gauze*, or *iodoform cotton wool*, may be made by saturating suitable material with a concentrated ethereal solution and afterwards drying.

The maximum amount of iodoform which may be used with safety as an external application is uncertain. Dr. Langenstein attributes a fatal result to one drachm, whilst one hundred and twenty grains have certainly caused death. Not more than half a drachm of iodoform should be ordinarily applied to a wound, although in cases of tuberculosis the surgeon is warranted in taking the risk of larger amounts. Verneuil sometimes injects at one sitting 75 grains of the iodoform.

One of the principal obstacles to its employment is the odor, which, to some patients, is unbearable. Many methods of disguising the odor have been recommended, but in our experience the large quantity required of each deodorizing agent would preclude its employment. Tannin has been recommended, but, as this operates by decomposing the iodoform, it is not to be thought of in this connection. Probably the best class of substances to use are the volatile oils, such as anise, peppermint, fennel, bergamot, almond, etc., tonka, coffee, and balsam of Peru, although the latter acts by forming a compound, and the aim should be not to destroy the odor,* but so to modify it as to remove its objectionable features. Olive oil saturated with camphor is said to dissolve 6 per cent. of iodoform, and is preferred by some surgeons.

IODUM. U. S., Br. Iodine.

I; 126·53. (Ī-Ō′DŬM.) I; 126·6.

"A solid non-metallic element obtained from the ashes of sea-weeds and from native iodides and iodates." *Br.*

Iodinium, *U. S.* 1870; Iode, *Fr.;* Jod, *G.;* Iodina, *It., Sp.*

The Iodine of the U. S. and Br. Pharmacopœias is considered as pure; and in both, the tests are given by which its purity may be determined. "Iodine should be kept in glass-stoppered bottles, in a cool place." *U. S.*

Iodine is a non-metallic element, discovered in 1812 by Courtois, a soda-manufacturer of Paris. It exists in certain marine vegetables, particularly the fuci or common sea-weeds, which have long been its most abundant natural source. It has been detected in some fresh-water plants, among which are the water-cress, brooklime, and fine-leaved water-hemlock; also in the ashes of tobacco, and of Honduras sarsaparilla. (*Chatin.*) It has been found in the beet-root of the grand-duchy of Baden. (*Lamy.*) Dr. Macadam detected a trace of iodine in 100 gallons of water used for domestic purposes in Edinburgh, in several of the domestic animals, and in man. He detected it also in potatoes, beans, peas, wheat, barley, and oats. (*P. J. Tr.*, Nov. 1854, p. 235.) Iodine is, moreover, found in the animal kingdom, as in the sponge, the oyster, various polypi, cod-liver oil, and eggs; and, in the mineral kingdom, in sea-water in minute quantity, in certain salt springs, as silver iodide in a rare Mexican mineral, in a zinc ore of Silesia, in native sodium nitrate, and in some kinds of rock salt. It is now obtained commercially from one of these sources,—viz., from the native sodium nitrate, or Chili saltpetre, with which it occurs as sodium iodate. The production of the province of Tarapaca (Chili) has assumed large dimensions within recent years, as a result of higher prices established by a combination of Scotch, French, and South American producers. The exportations of iodine from Chili amounted in 1893 to 595,000 kilos, valued at $5,953,420; in 1894 to 323,000 kilos, valued at $3,332,780; and in 1895 to 144,000 kilos, valued at $1,442,580. M. Bussy has obtained iodine, in the proportion of one part in five thousand, from the coal-gas liquor of the gas-works of Paris. It was first discovered in the United States in the water of the Congress Spring, at Saratoga, by Dr. William Usher. It was detected in the Kanawha saline waters by the late Professor Emmet; and it occurs in the bittern of the salt-works of

* The pale yellow essential oil of *Evodia fraxinifolia* is asserted by Mr. H. Helbing (*P. J. Tr.*, vol. xviii. 249) to have the power of covering the odor of iodoform.

Western Pennsylvania, in the amount of about eight grains to the gallon. In sea-weeds the iodine exists in the state probably of sodium iodide. In different countries sea-weeds are burned for the sake of their ashes, the product being a dark-colored fused mass called *kelp*. This substance, besides sodium carbonate and iodides, contains more or less common salt, potassium chloride, sodium sulphate, etc. The deep-sea fuci contain the most iodine; and when these are burned at a low temperature for fuel, as is the case in the island of Guernsey, their ashes furnish more iodine than does ordinary kelp. (Graham.) According to Dr. Geo. Kemp, the laminarian species, especially *Laminaria digitata*, *L. saccharina*, and *L. bulbosa*, which are deep-water sea-weeds, and contain more potassium than sodium, are particularly rich in iodine.

Preparation. Although most largely produced in South America, iodine is still obtained from kelp, and in Great Britain is manufactured chiefly at Glasgow. The kelp, which on an average contains $\frac{1}{224}$ part of iodine, is lixiviated with water, in which about half dissolves. The solution is concentrated to a pellicle and allowed to cool, whereby nearly all the salts, except sodium iodide, are separated, they being less soluble than the iodide. The remaining liquor, which is dense and dark-colored, is made very sour by sulphuric acid, which causes the evolution of carbonic acid, hydrogen sulphide, and sulphurous acid, and the deposition of sulphur. The liquor is then introduced into a leaden still, and distilled with manganese dioxide into a series of glass receivers, inserted into one another, in which the iodine is condensed. In this process the sodium iodide is decomposed, and the iodine evolved according to the reaction $2NaI + 2H_2SO_4 + MnO_2 = MnSO_4 + Na_2SO_4 + 2H_2O + I_2$ which leaves as residue manganous sulphate and sodium sulphate.*

The methods for the separation of the iodine from its combinations in the mother-liquors as practised in South America may be divided essentially into three classes. (1.) The mother-liquors after the crystallization of the saltpetre without further concentration are treated with a solution of sodium sulphite of strength corresponding to the amount of iodine present; the iodine is liberated according to the reaction $2NaIO_3 + 4HNaSO_3 + SO_2 = Na_2SO_4 + 4HNaSO_4 + I_2$; the iodine thus separated from the sodium iodate is filtered through linen cloth, washed, pressed, and sublimed. (2.) The mother-liquors are treated with sodium sulphite or bisulphite until the precipitated iodine is converted into HI, and this is precipitated as cuprous iodide by a solution of copper sulphate and sodium sulphite. (3.) The percentage of iodine is increased by fractional evaporation and crystallization of the mother-liquors, and then, after adding the calculated amount of sodium bisulphite, the iodine is distilled off from the acidified liquor. (*Dingler's Polytech. Journ.*, 231, p. 375.)

The British Pharmacopœia of 1864 purified iodine as follows: "Take of Iodine of Commerce *one ounce*. Introduce the Commercial Iodine into a porcelain capsule of a circular shape, cover this as accurately as possible with a glass flask filled with cold water, and apply to the capsule the heat of boiling water for twenty minutes. Let the flask be now removed, and should colorless acicular prisms of a pungent odor be found attached to its bottom, let them be separated from it. This being done, the flask is to be restored to its previous position, and a gentle and steady heat (that of a gas-lamp answers well) applied, so as to sublime the whole of the iodine. Upon now allowing the capsule to cool, and lifting off the flask, the purified product will be found attached to the bottom of the latter. When separated it should be immediately enclosed in a bottle furnished with an accurately ground stopper. In this process a short preliminary sublimation by the heat of a water-bath is ordered, in which the bottom of a glass flask filled with cold water is the refrigerator. The object of this is to separate

* The methods formerly practised for obtaining iodine from sea-weeds were accompanied with great loss. A notable improvement over the old kelp processes are the "char" and "wet" processes of Mr. E. C. C. Stanford (*Journ. Soc. Chem. Ind.*, 1885, p. 518), which show the following results when compared with the old processes. *Kelp process*: per cent. utilized, 18; kelp, 18 tons, yield salts 9 tons and iodine 270 lbs.; residuals, kelp waste 18 tons, valueless. *Char process*: per cent. utilized, 36; char, 36 tons, yield salts 15 tons and iodine 600 lbs.; residuals, charcoal 36 tons, tar, and ammonia. *Wet process*: per cent. utilized, 70; water extract, 33 tons, yield salts 20 tons and iodine 600 lbs.; residuals, algin 20 tons, cellulose 15 tons, dextrin, etc.

Still another improvement has recently been made (A. James, German Patent No. 95,063, of March 17, 1897), whereby over 91 per cent. of the iodine present in the sea-weed has been recovered. Sea-weed either wet or dry is immersed in sea-water that has previously been treated with quicklime to precipitate the magnesia and give a distinctly alkaline reaction. The sea-weed in the proportion of about one ton to the cubic metre of water is left immersed for twelve hours, during which time about 60 per cent. of the iodine is dissolved. It is then leached for six hours, each time in a second and a third portion of prepared sea-water. The combined extraction waters are then treated with ferrous sulphate, to coagulate mucilaginous matter, neutralized with sulphuric or hydrochloric acid, and the iodine then set free with an oxidizing agent like nitric acid or persulphate of ammonium, 1·5 kilos of nitric acid being required per cubic metre of solution. The iodine thus set free is extracted with petroleum naphtha, this solution being agitated with caustic alkali to form iodide and iodate, which are then treated in the usual manner.

any cyanogen iodide that may happen to be present. This impurity is sometimes present in considerable amount. Klobach obtained from eighty avoirdupois pounds of commercial iodine twelve ounces of this iodide, which is in the proportion of nearly one per cent. (*Chem. Gaz.*, April 15, 1850.) Should the flask, upon its removal, have attached to its bottom white acicular crystals, these will be the iodide in question, and must be rejected. The flask having been replaced, heat is again applied until the whole of the iodine has sublimed and attaches itself to the cool bottom of the flask.

Water has sometimes been found in iodine to the extent of 15 or 20 per cent. If considerable, it is easily discovered by the iodine adhering to the inside of the bottle. M. Bolley estimates its amount by rubbing together, until the smell of iodine disappears, 30 grains of iodine with about 240 of mercury, in a small weighed porcelain dish, using a small weighed agate pestle. When complete combination has been effected, the whole is placed in a water-bath to dissipate the water. The loss of weight gives the amount of water in the iodine. (*Chem. Gaz.*, March 15, 1853, p. 118.) The presence of water is injurious only as it renders all the preparations of iodine weaker than they should be. In the former Ed. Pharmacopœia, directions were given to dry it, by placing it "in a shallow basin of earthenware, in a small confined space of air, with ten or twelve times its weight of fresh-burnt lime, till it scarcely adheres to the inside of a dry bottle."

Properties. Iodine is described by the U. S. Pharmacopœia as "heavy, bluish-black, dry and friable, rhombic plates, having a metallic lustre, a distinctive odor, and a sharp and acrid taste. Specific gravity, 4·948 at 17° C. (62·6° F.). Iodine imparts a deep brown, slowly evanescing stain to the skin, and slowly destroys vegetable colors. Soluble in about 5000 parts of water, and in 10 parts of alcohol at 15° C. (59° F.) with a brown color; also freely soluble in ether, and in a solution of potassium iodide with a brown color; and in chloroform or carbon disulphide with a violet color. It volatilizes slowly at ordinary temperatures. When heated to 114° C. (237·2° F.), it melts, and is gradually dissipated in form of a purple vapor, leaving no residue. With starch test-solution it produces a dark blue color." "Soluble in about 5000 parts of *water*, but freely dissolved by *alcohol* (90 per cent.), *ether*, *chloroform*, or *solution of potassium iodide*. The aqueous solution strikes a deep blue color with *mucilage of starch*. It sublimes without residue, and the portion that first comes over does not include any slender colorless prisms emitting a pungent odor (absence of iodine cyanide)." *Br.* It is a volatile substance, and evaporates even at common temperatures. Its vapor has the sp. gr. 8·7, being the heaviest aëriform substance known. If inhaled mixed with air, it excites cough and irritates the nostrils. When it comes in contact with cool surfaces, it condenses in brilliant steel-gray crystals. Iodine is freely soluble in alcohol and ether, but requires 5000 times its weight of water to dissolve it. If water stands on iodine for some time, especially in a strong light, it apparently dissolves more iodine; but the result depends upon the formation of hydriodic acid, in a solution of which iodine is more soluble than in water. The solution of iodine in water has no taste, a feeble odor, and a light-brown color; its solution in alcohol or ether is nearly black. Its solubility in water is very much increased by the addition of certain salts, as sodium chloride, ammonium nitrate, or potassium iodide; and the same effect is produced, to some extent, by tannic acid. Its solution in tannic acid is called *iodo-tannin*, of which MM. Socquet and Guillermond make a syrup for internal and an aqueous solution for external use. For the formulas, see *B. and F. Med.-Chir. Rev.*, 1854, p. 181. It is also soluble in glycerin, as ascertained by M. Cap in 1854. According to Dr. I. Walz, glacial acetic acid is an excellent solvent of iodine, at least equal to alcohol. When the acid is heated by boiling with excess of iodine, and then allowed to cool slowly, it deposits iodine in beautiful large slender crystals, sometimes half an inch long, much larger and more abundant than those formed from the alkaline solution. (*Chem. News*, May 9, 1873, p. 233; from the *Journal of the Franklin Institute.*) In chemical characters iodine resembles chlorine, but its affinities are weaker. It combines with most of the non-metallic and nearly all the metallic elements, forming a class of compounds called *iodides*. Some of these are official, as the iron, mercury, lead, potassium, and sulphur iodides. It forms with oxygen one oxide, *iodic oxide*, I_2O_5, and two acids, *iodic** and *periodic*, and with hydrogen a gaseous acid, called *hydriodic acid*.

Tests, etc. Iodine, in most cases, may be recognized by its characteristic purple vapor;

* Dr. R. H. Brett, of Liverpool, has found that when a small portion of the alkaloids, or their salts, is mixed with about an equal portion of iodic acid and a few drops of water, and the mixture gently heated, a succession of distinct explosions, attended by the evolution of gas, takes place. Dr. Brett finds that this phenomenon does not occur with other organic substances, and suggests it as a general test for alkaloids. (*P. J. Tr.*, Nov. 1854.)

but, where this cannot be made evident, it is detected unerringly by starch, which produces with it a deep-blue color. The test was discovered by Colin and Gaultier de Claubry, and is so delicate that it will indicate the presence of iodine in 450,000 times its weight of water. In order that the test may succeed, the iodine must be free, and the solutions cold. To render it free when in combination, as it always is in the animal fluids, a little nitric acid, free from iodine, must be added to the solution suspected to contain it. Thus, in testing urine for iodine, the secretion is mixed with starch, and acidulated with a drop or two of nitric acid; when, if iodine be present, the color produced will vary from a light purple to a deep indigo-blue, according to the amount of the element present. Sometimes in mineral waters the proportion of iodine is so minute that the starch test, in connection with nitric acid, gives a doubtful coloration. In such cases, Liebig recommends the addition to the water of a very small quantity of potassium iodate, followed by a little starch and hydrochloric acid. Assuming the iodine to be present as hydriodic acid, the liberated iodic acid sets free the iodine of the mineral water, and becomes itself deoxidized, thus increasing the amount of the free iodine ($HIO_3 + 5HI = 3I_2 + 3H_2O$). This test would be fallacious if iodic acid, mixed with hydrochloric acid, colored starch; but this is not the case. Still, Liebig's test is inapplicable in the presence of reducing agents, such as sulphurous acid, which would give rise to free iodine from the test itself, independently of the presence of the element in the water tested. (*Dr. W. Knop.*) The U. S. Pharmacopœia furnishes the following tests: "A solution of Iodine in chloroform should be perfectly clear and limpid (absence of *moisture*). To determine the presence of *cyanogen*, *chlorine*, or *bromine*, proceed as follows: Triturate 0·5 Gm. of finely-powdered Iodine with 20 C.c. of water, and filter off the solution. To one-half of this solution, in a test-tube, carefully add sodium hyposulphite decinormal volumetric solution, until the solution is just decolorized. Then add a few drops of ferrous sulphate test-solution, and subsequently a little sodium hydrate test-solution, and heat the mixture gently. On now adding a slight excess of hydrochloric acid, the liquid should not assume a blue color (absence of *iodine cyanide*). To the other half of the aqueous filtrate, in a test-tube, add a slight excess of silver nitrate test-solution, shake actively, allow the precipitate to subside, and, having poured off the clear, supernatant liquid completely, shake the precipitate with a mixture of 1 C.c. of ammonia water and 9 C.c. of water, and filter. Upon the addition of a slight excess of nitric acid to the filtrate, not more than a slight opalescence should make its appearance (limit of *chlorine* or *bromine*). If 0·32 Gm. of Iodine, together with 1 Gm. of potassium iodide, be dissolved in 20 C.c. of water, and the solution mixed with a few drops of starch test-solution, it should require not less than 25 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (corresponding to at least 98·85 per cent. of pure Iodine)." The British Pharmacopœia states that "A solution of Iodine in *chloroform* should be perfectly clear (absence of moisture). Each gramme, dissolved in 50 cubic centimetres of *water* containing 2 grammes of *potassium iodide*, should require for decoloration at least 78·4 cubic centimetres of the *volumetric solution of sodium thiosulphate*." M. Carey Lea proposes chromic acid as a substitute for the nitric, for the liberation of iodine, as a more delicate test. It may be most conveniently applied by first adding starch to the liquid to be tested, and then a little dilute solution of potassium bichromate, enough to cause a pale yellow color, followed by a few drops of hydrochloric acid. (*Am. Journ. of Sci. and Arts*, xlii. 109.) Another test for iodine, proposed by M. Rabourdin, is chloroform, by the use of which he supposes that the element may be not only detected in organic substances, but approximately estimated. Thus, if 150 grains of a solution, containing one part in one hundred thousand of potassium iodide, be treated with 2 drops of nitric and 15 or 20 of sulphuric acid, and afterwards shaken with 15 grains of chloroform, the latter acquires a distinct violet tint. M. Rabourdin applies his test to the detection of iodine in the several varieties of cod-liver oil. For this purpose he incinerates, in an iron spoon, 50 parts of the specimen of oil with 5 of *pure* caustic potassa, dissolved in 15 of water, and exhausts the cinder with the smallest possible quantity of water. The solution is filtered, acidulated with nitric and sulphuric acids, and agitated with 4 parts of chloroform. After a time the chloroform subsides, of a violet color more or less deep according to the proportion of iodine present. M. Lassaigne considers the starch test more delicate than that of chloroform. For detecting iodine in the iodides of the metals of the alkalies, he considers palladium bichloride as extremely delicate, producing brownish flocks of palladium biniodide. According to M. Moride, benzin is a good test for free iodine, which it readily dissolves, forming a solution of a bright-red color, deeper in proportion to the amount of iodine taken up. As benzin does not dissolve chlorine or bromine, it furnishes the means of separating iodine

from these elements. Mr. D. S. Price has pointed out the nitrites as exceedingly sensitive tests of iodine combined as an iodide. The suspected liquid is mixed with starch paste, acidulated with hydrochloric acid, and treated with solution of potassium nitrite. The iodine is set free, and a blue color appears, more or less deep, according to the proportion of iodine present. By this test, iodine may be detected in an aqueous solution containing only one in 400,000 parts. A similar test had been previously proposed by M. Grange.

It has been long known that when a mixture of iodine and starch in water is subjected to heat the blue color disappears, and that, if the heat be not too long continued, so as to volatilize the iodine or convert it into hydriodic acid, the color will return on the cooling of the liquid. Various explanations have been given of this curious fact by Personne and others, but the only one that is quite satisfactory is that by M. Magnes-Lahens, which he supports by experiment, that during the continuance of the heat the particles of starch and iodine separate, to unite again on refrigeration. (*Journ. de Pharm.*, 4e sér., iii. 405.)*

Adulterations. Iodine is said to be occasionally adulterated with mineral coal, charcoal, plumbago, and black manganese oxide. These are easily detected by their fixed nature, while pure iodine is wholly volatilized by heat. Herberger found native antimony sulphide in one sample, and plumbago in another; and Righini has detected as much as 25 per cent. of calcium chloride. The presence of cyanogen iodide and of water has already been referred to, and the modes of detecting and separating them pointed out. (See page 745.) Besides the test given at page 745, the British Pharmacopœia directs that the official iodine should be soluble in alcohol, ether, and a solution of potassium iodide, and should sublime without residue, and that the part which first comes over should contain no colorless prisms of a pungent odor.

Medical Properties. Iodine was first employed as a medicine in 1819, by Dr. Coindet, Sr., of Geneva. It operates as a general excitant of the vital actions, especially of the absorbent and glandular systems. Its effects are varied by its degree of concentration, state of combination, dose, etc.; and hence under different circumstances it may prove corrosive, irritant, or simply alterative. It is absorbed into the circulation, and may be found in all the secretions, but is chiefly eliminated by the kidneys, not, however, uncombined, but in the state of hydriodic acid or an iodide. Cantu detected it not only in the urine and saliva, but also in the sweat, milk, and blood. According to Dr. John C. Dalton, Jr., of New York, iodine, taken in a single moderate dose, appears in the urine in thirty minutes, and may be detected for nearly twenty-four hours. In two cases in which large doses of potassium iodide had been taken for six or eight weeks, and the medicine intermitted, all trace of iodine disappeared from the urine in eighty-four hours.

In an overdose iodine acts as an irritant poison. From four to six grains (0·26 to 0·4 Gm.), in man, cause a sense of constriction in the throat, sickness and pain at the stomach, and at length vomiting and colic. Even in medicinal doses it sometimes causes alarming symptoms, such as fever, restlessness, disturbed sleep, palpitations, excessive thirst, acute pain in the stomach, vomiting and purging, violent cramps, frequent pulse, and, finally, progressive emaciation if the medicine be not laid aside. Such violent symptoms are, however, very rare, but where iodine or potassium iodide is given freely a mild *iodism* is not unfrequent. It is usually characterized by pain or heaviness in the region of the frontal sinuses, with or without coryza; in some instances soreness of the mucous membrane of the mouth and throat, or a mild ptyalism, is the prominent symptom; or a papular eruption may be the first manifestation of the constitutional action of the remedy. Absorption of the mammæ and wasting of the testicles have been reported as caused by the long-continued use of the drug, but such results are extremely rare. Dr. Lebert noted that the accidents produced by iodine, with scarcely an exception, were in those cases of goitre in which the remedy acted rapidly in removing the tumor,

* *Amylum Iodatum.* U. S. 1880. *Iodized Starch.* (*Amyli Iodidum, Iodide of Starch; Iodure d'Amidon*, Fr.; *Jodstärke*, G.) "Starch, *ninety-five parts* [or four hundred and eighteen grains]; Iodine, *five parts* [or twenty-two grains]; Distilled Water, *a sufficient quantity*, To make *one hundred parts* [or one ounce av.]. Triturate the Iodine with a little Distilled Water; add the Starch gradually, and continue triturating until the compound assumes a uniform blue color, approaching black. Dry it at a temperature not exceeding 40° C. (104° F.), and rub it to a fine powder. Iodide of Starch should be preserved in glass-stoppered vials." *U. S.*

Medical Properties. This preparation has been highly recommended as free from local irritant properties. Prof. Dalton, of New York, found that nearly all the animal fluids decompose starch iodide and destroy its blue color. (*Am. Journ. of Med. Sci.*, April, 1856, p. 327.) This result is owing, no doubt, to the alkaline nature of most of the animal fluids, especially those of the duodenum, alkaline iodides being formed at the expense of the starch. The dose is a heaped teaspoonful, given in water-gruel, three times a day, and afterwards increased to a tablespoonful. No nicety is necessary in apportioning the dose. In some cases Dr. Buchanan has given half-ounce (15·6 Gm.) doses, increased to an ounce (31·1 Gm.).

and believed that the bad effects arose from the too prompt absorption of the abnormal material of the tumor, and not from the iodine itself. (*Ann. de Thérap.*, 1855, 228.) The modern discovery that the active principle of the thyroid body is capable of producing rapid wasting singularly confirms the old observation and theory of Lebert.

Iodine has been principally employed in diseases of the glandular system. It has been used with success in *ascites*, especially when connected with diseased liver. It acts most efficiently immediately after tapping. In glandular enlargements and chronic indurations it is often of great service. Dr. Coindet discovered its extraordinary power in curing *goitre*;* and it has been used with more or less advantage in enlargements and indurations of the liver, spleen, mammæ, testes, and uterus. In hepatic affections of this kind, where mercury has failed or is inadmissible, iodine is our best resource. Dr. Morell Mackenzie reports very favorably of the effects of iodine injected hypodermically into the thyroid. (*Am. Journ. Med. Sci.*, Oct. 1873, 553.) In chronic diseases of the uterus, with induration and enlargement, and in hard tumors of the cervix and indurated puckerings of the edges of the os tincæ, iodine has occasionally effected cures, when administered internally and locally applied. In the form of potassium iodide in *advanced syphilis*, *mercurial cachexia*, and *lead-poisoning*, it is one of our best remedies. It is habitually employed in *scaly skin affections* and in *chronic rheumatism*. Dr. Coindet first directed attention to its effects in *scrofula*, but Dr. Lugol, by numerous trials in the Hôpital Saint-Louis, extending from 1827 to 1831, first established the value of the remedy.

The most eligible form of iodine for internal administration is its solution in water, aided by potassium iodide. (See *Liquor Iodi Compositus.*) The solutions employed by Dr. Lugol contained one part of iodine and two parts of potassium iodide; and the doses given by him were equivalent to half a grain (0·03 Gm.) of iodine daily for the first fortnight, three quarters of a grain (0·05 Gm.) daily for the second and third fortnights, one grain (0·065 Gm.) daily during the fourth and fifth fortnights, and, in some cases, a grain and a quarter (0·081 Gm.) daily for the remainder of the treatment; always largely diluted. The tincture of iodine is not eligible for internal use; for, when freshly prepared, the iodine is precipitated from it by dilution with water, and, as a consequence, the irritating solid iodine will come in contact with the stomach when the dose is swallowed. The same objection is not applicable to the compound tincture, or to the simple tincture after having been long kept.

A mode of safely bringing and maintaining the system under the influence of iodine, proposed by M. Boinet and called by him *iodic alimentation*, is to mix the medicine with the food, as with bread and other farinaceous substances, so that the patient may take daily a due quantity, which, with this mode of administration, may be large, if desirable, without inconvenience. (See *Amylum Iodatum.*) †

* M. Chatin, finding, according to his observations, a great variation in the amount of iodine in the air, water, and soil of different localities, has founded on this supposed fact an explanation of the prevalence of goitre and cretinism in some places and their absence in others. Thus, in certain parts of France, near Paris, which he calls the Paris zone, the amount of iodine thus distributed is comparatively large, and goitre and cretinism are unknown; while in the Alpine valleys, where only one-tenth the amount of iodine is found, these affections are endemic. These conclusions are controverted by M. Lohmeyer, of Göttingen, and M. Kletzinsky, of Vienna, who failed to detect iodine in the air of those cities the inhabitants of which are free from goitre.

† *Iodized Oil.* The following is the original process of M. Personne. Five parts of iodine are mixed with a thousand parts of almond oil, and the mixture is subjected to a jet of steam, until decolorized. The same operation is repeated with five additional parts of iodine. The oil is then washed with a weak alkaline solution, to remove the hydriodic acid developed in the process. By this mode of proceeding it may be presumed that the iodine is intimately united with the oil, along with which it would find an easy entrance into the system, and that, while about half of the iodine is lost as hydriodic acid, the remainder takes the place of the hydrogen eliminated from the oil. In 1851 the French Academy appointed MM. Guibourt, Soubeiran, Gibert, and Ricord to report upon the therapeutic value of a definite combination of iodine and oil. The reporter (Guibourt) approved of M. Personne's process; and MM. Gibert and Ricord reported favorably of the therapeutic effects of the preparation. M. Personne's iodized oil differs little in appearance and taste from almond oil, and is easily taken alone or in emulsion. The dose is two fluidounces (60 C.c.) daily, which may be increased to three fluidounces (90 C.c.) or more. (*Am. Journ. of Med. Sci.*, xxiii. 502.)

M. Berthé and M. Lepage have objected to M. Personne's iodized oil, that it is of variable iodine strength, and that it is liable to become rancid, in consequence of the use of steam in its preparation. M. Berthé makes an iodized oil which he alleges to be free from these objections, by heating to about 176° five parts of iodine with a thousand parts of almond oil, in a water-bath, until decoloration has taken place. The resulting oil is colorless, perfectly transparent, without odor or rancidity, not acted on by starch, and of a constant composition. To shorten the time in preparing the oil, M. Lepage dissolves the iodine in three times its weight of ether, before adding it to the oil, and briskly shakes the mixture for eight or ten minutes. The preparation is then heated in a water-bath, to decolorize it and drive off the ether. M. Hugounenq objects to this process that, if the oil be completely deprived of the odor of ether, the heating must be continued for several hours. He also objects to any process which requires the continued application of heat, as rendering the oil liable to become quickly rancid. His plan is to rub up the iodine, for five or six minutes, in a porcelain mortar, with a small portion of the oil, and then gradually to add the remainder. A red limpid liquor is obtained, which may be completely decolorized by exposure for fifteen minutes to the sun's rays.

According to M. Hutet, one grain of iodine is deprived entirely of taste and smell by one teaspoonful of a strong infusion of coffee. (*P. J. Tr.*, Dec. 1870.)

The external treatment of iodine may be divided into general and topical. By its use in this way it does not create a mere local effect, but, by its absorption, produces its peculiar constitutional impression. The external treatment, when general, consists in the use of the *iodine bath*. This for adults should contain from two to four drachms of iodine, with double that quantity of potassium iodide, dissolved in water, in a *wooden* bath-tub; the proportion of the water being about a gallon for every three grains of iodine employed. The quantity of ingredients for the baths of children is one-third as much as for adults, but dissolved in about the same quantity of water. The quantity of iodine and iodide for a bath having been determined upon, it is best to dissolve them in a small quantity of water (half a pint, for example) before they are added to the water of the bath; as this mode of proceeding facilitates their thorough diffusion. The iodine baths, which may be directed three or four times a week, usually produce a slight rubefacient effect, but occasionally a stronger impression, causing the epidermis to peel off, particularly of the arms and legs. The skin at the same time acquires a deep yellow tinge, which usually disappears in the interval between the baths.

The topical application of iodine is made by means of several official preparations. (See *Unguentum Iodi* and *Tinctura Iodi*.) Besides these, several others have been employed topically. Lugol's *iodine lotion* consists of from two to four grains of iodine, and double that quantity of potassium iodide, dissolved in a pint of water. It is used as a wash or an injection in scrofulous *ophthalmia*, *ozæna*, and *fistulous ulcers*. His *rubefacient iodine solution* is formed by dissolving half an ounce of iodine and an ounce of potassium iodide in six fluidounces of water. This is useful for exciting scrofulous ulcers, for touching the eyelids, and as an application to recent scrofulous cicatrices, to render them smooth. The rubefacient solution, added to warm water in the proportion of about a fluidrachm to the gallon, makes a convenient local bath for the arms, legs, feet, or hands; and, mixed with linseed meal or some similar substance, it forms a cataplasm useful in certain eruptions, especially where the object is to promote the falling off of scabs. External applications of iodine have been recommended for the removal even of internal plastic exudations, as to the side, for example, in protracted pleurisy. The rubefacient preparation of iodine at present most commonly employed is the tincture. (See *Tinctura Iodi*.) The preparation called *iodine paint* is a tincture twice as strong as the official tincture, and is made by dissolving a drachm of iodine in a fluidounce of alcohol, and allowing the solution to stand in a glass-stoppered bottle for several months before it is used, when it will become thick and syrupy. It is applied with a glass or a camel's-hair brush, in one or more coatings, according to the degree of effect desired. Iodine paint is used as a counter-irritant, with advantage, in almost all forms of deep-seated chronic inflammation. When thus used, it must be borne in mind that the iodine acts also by being absorbed. Another valuable application of it is for the removal of *nævi*. Lugol's *caustic iodine solution* is made of iodine and potassium iodide, each, an ounce, dissolved in two fluidounces of water. This is used to destroy soft and fungous granulations, and has been employed with decided benefit in *lupus*. The *Strong Solution of Iodine* of the British Pharmacopœia is intermediate in strength between the two solutions last mentioned. (See *Liquor Iodi Fortis*.) Another caustic solution of iodine, under the name of *iodized glycerin*, is made by dissolving one part of potassium iodide in two parts of glycerin, and adding the solution to one part of iodine, which it completely dissolves. Dr. Max Richter, of Vienna, to whom belongs the credit of having introduced into practice the solution of iodine in glycerin, found this caustic particularly useful in lupus, non-vascular goitre, and scrofulous and constitutional syphilitic ulcers. The solution is applied by means of a hair-pencil to the diseased surface, which must then be covered with gutta-percha paper, fixed at the edges by strips of adhesive plaster, in order to prevent the evaporation of the iodine. The application produces burning pain, which rarely lasts for more than two hours. The dressing is removed in twenty-four hours, and pledgets dipped in cold water applied. This iodine caustic is too strong for ordinary local use. A weaker solution is recommended by Dr. Szukits, formed of one part of iodine to five parts of glycerin, for application to the neck, female breast, abdomen, etc. After four or five paintings it causes excoriation, which requires its discontinuance and the use of cold applications. A mode of applying iodine locally has been

Iodized oil, thus prepared, has the odor and taste of almond oil, is not more liable to become rancid than the pure oil, and is free from hydriodic acid. (*Journ. de Pharm.*, Mars, 1856.) From the above statements it is not easy to determine which is the best method of preparing iodized oil; but the preparation may be made with good olive oil instead of the more expensive almond oil.

suggested by Dr. R. Greenhalgh, of London, which consists in thoroughly impregnating raw cotton with a solution in glycerin of potassium iodide and of iodine, in the proportion of two ounces of the former and one ounce of the latter to eight ounces of the menstruum, and then drying the "*iodized cotton.*" It is intended for application to the cervix or os uteri, which is effected through a speculum. (*Lancet*, May 26, 1866, p. 582.) Méhu's method of making iodized cotton is as follows. Finely divided iodine (5 to 10 parts) is sprinkled between layers of loose cotton (100 parts) introduced into a tall glass vessel, and the latter placed horizontally on a water- or sand-bath. As soon as vapors of iodine are seen to rise, and the air has been expelled from the vessel, the latter is tightly stoppered. On continuing to apply a moderate and uniform heat, the iodine vapors penetrate the cotton, and color it yellow. After about two hours, the cotton will have assumed the color of burnt coffee, and the operation is finished. Cotton iodized in other ways, as by immersion in concentrated solutions of iodine in ether or carbon disulphide, retains merely traces of iodine. (*N. R.*, April, 1867.)

Iodine is used by injection into various cavities. It has been employed in this way for the cure or relief of *hydrocephalus*, *pleuritic effusion*, *hydropericardium*, *ascites*, *ovarian dropsy*, *hernia*, *hydrocele*, *spina bifida*, *dropsy of the joints*, *large cystic bronchocele*, and *chronic abscesses*. The discussion of the indications for the use of the injections in these cases, and of the precautions and the methods to be adopted, belongs rather to treatises upon the practice of medicine and surgery than to a work like the present. To such treatises, therefore, the reader is referred.

Enemata containing iodine have been used, by several practitioners, in the *chronic dysentery* and *diarrhœa* of both adults and children, with decided benefit, a prominent effect being the relief of tenesmus. They are supposed to act locally on ulcers in the colon and rectum, and generally by absorption. The injection should be made of Lugol's solution, one to ten fluidrachms in one or two quarts of water. It should be preceded by an emollient enema to empty the intestine, and should be repeated once or twice daily, gradually increasing its strength. If the pain be severe, a laudanum injection will bring immediate relief.

Iodine, in the state of vapor, has been employed by inhalation; and the experiments as yet tried have been in the treatment chiefly of *phthisis* and *chronic bronchitis*. Although very extraordinary results were claimed for the method, yet it has entirely failed to fulfil expectations, and is at present very rarely practised. For details as to methods, the reader is referred to the 14th edition of the U. S. D.*

Iodine or an iodide should not be given in solution with an alkaloid, as it forms insoluble compounds, and in Philadelphia death has been produced by the strychnine iodide which had crystallized out of a mixture. It has even been suggested by Mr. R. F. Fairthorne (*A. J. P.*, 1856) and Dr. H. W. Fuller (*Lancet*, March 21, 1868, p. 373) as an antidote to alkaloids; but the insoluble compounds of these substances would by no means be inert in the stomach.

In cases of poisoning by iodine, the stomach must first be evacuated, and afterwards drinks administered containing an amylaceous substance, such as flour, starch, or arrow-root.

IPECACUANHA. U. S. (Br.) Ipecac.

(ĬP-Ē-CĂC-Ū-ĂN'HA.)

"The root of Cephaëlis Ipecacuanha (Brotero), A. Richard (nat. ord. Rubiaceæ)." *U. S.*
"The dried root of Psychotria Ipecacuanha, Stokes." *Br.*

The term *ipecacuanha*, derived from the language of the aborigines of Brazil, has been applied to various emetic roots of South American origin.† The botanical character of the ipecacu-

* M. Barrère has proposed the use, for inhalations, of *iodized camphor*, which is to be taken like snuff. This is prepared by putting powdered camphor in a snuff-box, with a hundredth part in bulk of iodine, contained in a muslin bag. In the course of a few hours the substances, by occasional shaking, unite, forming a powder resembling iodine in color. The difficulty in practising ordinary iodine inhalation depends chiefly on the irritation caused by the vapor, which excites cough and fatigues the patient. According to M. Barrère, this inconvenience is avoided by the use of the iodized camphor. A pinch of it produces sneezing and some smarting in the nostrils, but when the vapor reaches the lungs it causes a refreshing sensation, which induces the patient to draw a long and deep breath. (*Ann. de Thérap.*, 1855, p. 232.) M. Hutet recommends the inhalation of hydriodic ether in affections of the lungs.

Dr. Brainard employs the vapor of iodine, with great advantage, in the treatment of *indolent ulcers*, first dressing the ulcer with simple cerate spread on lint, then applying over this several layers of lint in which from one to four grains of iodine have been folded, and covering the whole with oiled silk and tin foil, secured by a bandage, so as to prevent the escape of the iodine, which is vaporized by the heat of the body. (*Chicago Med. Journ.*, Jan. 1860.)

† M. Weddell states that the word ipecacuanha is nowhere in Brazil used to designate the Cephaëlis, which is generally called *poaya*. (*Journ. de Pharm.*, 3e sér., xvi. 34.)

anha plant of commerce was long unknown. Piso and Marcgraf, who were the first to treat of this medicine, in their work on the Natural History of Brazil, published at Amsterdam in 1648, described in general terms two plants,—one producing a whitish root, distinguished by the name of white ipecacuanha, the other a brown root, which answers in their description precisely to the official drug. But their account was not sufficiently definite to enable botanists to decide upon the character of the plants. The medicine was generally thought to be derived from a species of *Viola*, which Linnæus designated as *V. ipecacuanha*. Opinion afterwards turned in favor of a plant sent to Linnæus by Mutis from Colombia, as affording the ipecacuanha of that country and of Peru. This was described in the *Supplementum* of the younger Linnæus, 1781, under the name of *Psychotria emetica*, and was long erroneously considered as the source of the true ipecacuanha. Dr. Gomez, of Lisbon, was the first who accurately described and figured the genuine plant, which he had seen in Brazil, and specimens of which he took with him to Portugal; but Brotero, professor of botany at Coimbra, with whom he had left specimens, having drawn up a description and inserted it with a figure in the Linnæan Transactions without acknowledgment, enjoyed for a time the credit due to his countryman. In the paper of Brotero (1802) the plant is named *Callicocca ipecacuanha;* but the term *Callicocca*, having been applied by Schreber (1789), without sufficient reason, to a genus already named, the name of Cephaëlis Swartz (1788) has been largely used. As, however, the Linnæan name Uragoga was given in 1731, it will probably be preferred by botanists. According to Engler and Prantl, the principal synonymes of the ipecacuanha plant are, besides the official botanical names, *Cephaëlis Ipecacuanha* Willd., *Psychotria Ipecacuanha* Müll.-Arg., and *Uragoga Ipecacuanha* Baill., which latter is probably the name that will finally prevail. 150 species of the genus Uragoga, according to Engler and Prantl, are to be found in the tropics, of which 100 grow in Brazil. The genus is divided into 4 sections, of which the Enuragoga comprises 73 species, most of which are found in Brazil.

Ipecacuanha, transverse section.

Cephaëlis ipecacuanha. Richard, *Hist. Ipecac.* p. 21, t. i.; Martius, *Spec. Mat. Med. Brazil.* t. i. p. 4; *Curtis's Bot. Mag.*, N. S., vol. xvii. pl. 4083, 1844.—*Callicocca ipecacuanha.* Brotero, *Linn. Trans.* vi. 137. This is a small shrubby plant, with a root from four to six inches long, about as thick as a goose-quill, marked with annular rugæ, simple or somewhat branched, descending obliquely into the ground, and here and there sending forth slender fibrils. The stem is two or three feet long, but, being partly under ground, and often procumbent at the base, usually rises less than a foot in height. It is slender; in the lower portion leafless, smooth, brown or ash-colored, and knotted, with radicles frequently proceeding from the knots; near the summit, pubescent, green, and furnished with leaves seldom exceeding six in number. These are opposite, petiolate, oblong-obovate, acute, entire, from three to four inches long, from one to two broad, obscurely green and somewhat rough on their upper surface, pale, downy, and veined on the under. At the insertion of each pair of leaves are deciduous stipules, embracing the stem, membranous at the base, and separated above into numerous bristle-like divisions. The flowers are very small, white, and collected to the number of eight, twelve, or more, each accompanied with a green bract, into a semi-globular head, supported upon a round, solitary, axillary footstalk, and embraced by a monophyllous involucre, deeply divided into four, sometimes five or six, obovate, pointed segments. The fruit is an ovate, obtuse berry, which is at first purple, but becomes almost black when ripe, and contains two small plano-convex seeds.*

The plant is a native of Brazil, flourishing over a very wide extent of territory in moist, thick, and shady woods, and abounding most within the limits of the eighth and twentieth degrees of south latitude. According to Humboldt, it grows also in Colombia. It flowers in January and February, and ripens its fruit in May. The root is active in all seasons, but, as it has to be dried rapidly, collection during the rainy season is relaxed. The native collector, or *poayero*, seizes all the stems of a clump, loosens them by a zigzag motion, and then, thrusting a pointed stick under the roots, tears up the whole mass. The roots, freed from dirt by shaking,

* *Cephaëlis tomentosa*, of Trinidad, has been studied by Mr. Francis Ransom, who finds that it contains emetine, but in too small quantity for commercial purposes. For description of the root, etc., see *P. J. Tr.*, xix. p. 258.

are then dried. The amount gathered daily varies from 8 to 30 pounds, according to skill and locality. Extirpation does not take place, because, as shown by the Edinburgh gardeners McNab and Lindsay, a very small fragment of the root, or even a petiole of a leaf, will rapidly produce a new plant. Weddell, indeed, many years since, stated that the remains of the root, often purposely left in the ground, serve the purpose of propagation, each fragment giving rise to a new plant. Ipecacuanha of commerce comes chiefly from the interior province of Matto-Grosso, upon the upper waters of the Paraguay (from which in some years as much as 450,000 kilos are shipped), although some is said to be gathered near Philadelphia, north of Rio Janeiro. The chief places of export are Rio Janeiro, Bahia, and Pernambuco. It is brought to the United States in large bags or bales.

The cultivation of ipecacuanha, which commenced in India as long ago as 1866, met with no success until within a very few years, and even yet the culture has not become commercially important. Ransom has shown that the India roots are equal in alkaloidal contents to the wild ipecacuanha of America.*

* Unofficial Ipecacuanhas. From time to time there have been imported into Europe various drugs stated to be ipecacuanha, but differing from the official drug. Of these the most important are White Ipecacuanha; the Larger Striated Ipecacuanha of M. Planchon (*Journ. de Pharm.*, Déc. 1872); and the Lesser Striated Ipecacuanha of Planchon.

White Ipecacuanha. Amylaceous Ipecacuanha. Undulated Ipecacuanha. Larger Undulated Ipecacuanha. Ipecacuanha of Carthagena. The origin of this variety of ipecacuanha was attributed by Martius to species of *Richardsonia* (*Richardia* of Linnæus), especially *R. scabra*, *R. braziliensis* of Gomez, and *R. emetica*; but an authentic specimen of the plant, received from Colombia, was found by Hanbury to resemble very closely the official ipecacuanha plant; and H. Baillon has described the source of white ipecacuanha as a new species of *Psychotria* or *Uragoga*, under the specific name of *granatensis*, syn. *Psychotria emetica* Mutis (not Vell): the plant is probably merely a variety of the official species. White ipecacuanha occurs in fragments from 5 to 8 millimetres in diameter, cylindrical, marked with rings which are but little pronounced and often wanting. Its color is whitish gray, sometimes verging towards reddish or yellowish. When broken it shows a very thick, hard, horny bark, with a dry, whitish or grayish-brown or black, farinaceous surface, offering in the full sunlight little shining points. It is chiefly distinguished from the official drug by its greater size, its gray external color, the feebleness of its undulation, and the comparative smallness of its woody centre. It is inodorous and insipid, and contains, according to Pelletier, a very large proportion of starch, with only 6 per cent. of impure emetine and 2 per cent. of fatty matter. Richard found only three and one-half parts of emetine in the hundred: M. Palangié found 3 per cent.: but in 1860 Lefort obtained from a specimen nearly as much emetine as occurs in the official roots. White ipecacuanha evidently varies in its strength, and, as it sometimes gets mixed with genuine roots, it would seem probable that it is the root of the official plant modified by climatic influence, or is composed of inferior roots obtained from very old specimens of the official plants. This probability is confirmed by the microscopic characters, the structure of the root being very closely similar to that of the official drug.

Larger Striated Ipecacuanha (Planchon). *Violet Striated Ipecacuanha. Ipecacuanha of St. Martha. Ipecacuanha of Carthagena. Striated Elastic Ipecacuanha* (Attfield). This variety of ipecacuanha is generally acknowledged to be the product of *Psychotria* (or *Uragoga*) *emetica*, growing in the deep forests of Colombia. This is a small shrub, with a stem twelve or eighteen inches high, simple, erect, round, slightly pubescent, and furnished with opposite, oblong-lanceolate, pointed leaves, narrowed at their base into a short petiole, and accompanied with pointed stipules. The flowers are small, white, and supported in small clusters towards the end of an axillary peduncle. The drug occurs in rather long fragments, sometimes 9 or 10 centimeters (3 or 4 inches), with a thickness of from 5 to 9 millimeters ($\frac{1}{5}$ to $\frac{1}{3}$ of an inch). The pieces are for the most part almost straight, sometimes sinuous, more rarely tortuous. At distant intervals they are marked by contractions, or circular furrows. Their whole surface is largely striated longitudinally. To their upper part are often attached one or more remaining portions of the stem, distinguished from the root by their much smoother surface. Their color is a grayish brown, tending sometimes to reddish brown. Like other ipecacuanhas, they have an outer cortical and a central ligneous portion. The former is soft, so that it may even be penetrated by the nail. It has a horny aspect, and a variable color, passing from whitish, by shades of rose, violaceous, and blackish violet. Its thickness is at least two-thirds of the root, and becomes still greater when this is immersed in water. The central part is yellowish white. The root has little odor, and a taste scarcely nauseous, sometimes flat, and often sweetish. As to the microscopic characters, the most striking are probably the total absence of the starch granules, and the relatively very small diameter of the vessels in the central part. Chemically this variety is characterized by the presence of a principle capable of reducing the cupro-potassic reagent. It is so abundant in the cortical part that a simple digestion in water gives a liquid with strong reducing powers, but without deviating action on polarized light. The larger striated ipecacuanha comes from Colombia.

Lesser Striated Ipecacuanha (Planchon). *Ipecacuanha des Côtes d'Or* (Pelletier). *Black Ipecacuanha. Black Striated Ipecacuanha. Striated Brittle Ipecacuanha* (Attfield). *False Ipecacuanha* (Holmes.) It is not known from what plant this is obtained. It occurs in very short fragments, 2 or 3 centimeters at most long, and 2 or 3 millimeters in thickness; some nearly cylindrical, others narrowly fusiform; others again formed of roundish or pyriform segments, somewhat thicker than the preceding, placed end to end. The color is generally of a gray brown, darker than that of the other kind. The longitudinal striæ are fine, and regular on the transverse section. The cortical portion is as it were horny, and its consistence firmer than in the larger kind; the central part is yellowish, and under the microscope exhibits numerous pores. The ligneous centre is at once distinguished by the size of its vessels, which give it a porous appearance. The presence of the starch granules is another of the distinguishing characters of this variety. It contains a larger proportion of emetine than the preceding, yielding, according to the analysis of Pelletier, 9 per cent.

According to Martius, different species of *Ionidium* (*Viola*, Linn.) also produce what is called *white ipecacuanha*. The roots of all the species of Ionidium possess emetic or purgative properties. The root of *I. ipecacuanha* is described by Guibourt as being six or seven inches long, as thick as a quill, somewhat tortuous, and exhibiting at the

Properties. Genuine ipecacuanha is in pieces two or three lines thick, variously bent and contorted, simple or branched, consisting of an interior slender, light straw-colored, ligneous cord, with a thick, brittle, brownish, finely wrinkled, cortical covering, which presents on its surface a succession of circular, unequal, prominent rings or rugæ, separated by very narrow fissures, frequently extending nearly down to the central fibre. This appearance of the surface has given rise to the term *annelé*, or *annulated*, by which the true ipecacuanha is designated by French pharmaceutists. The cortex is hard, horny, and semi-transparent, breaks with a resinous fracture, and easily separates from the tougher ligneous fibre, which possesses the medicinal virtues of the root in a much inferior degree. On microscopic examination the very thick bark is seen to be formed of uniform parenchymatous cells, without traces of the medullary rays, which are very distinct in the woody central cylinder. Attached to the root is frequently a smoother and more slender portion, which is the base of the stem, and should be separated before pulverization. Pereira has met, in the English market, with distinct bales composed of these fragments of stems, with occasionally portions of the root attached. Much stress has been laid upon the color of the external surface of the ipecacuanha root; and diversity in this respect has even led to the formation of distinct varieties. Thus, the epidermis is sometimes deep brown or even blackish, sometimes reddish brown or reddish gray, and sometimes light gray or ash-colored. Hence the distinction into *brown*, *red*, and *gray ipecacuanha*. But these are all derived from the same plant, are essentially the same in properties and composition, and probably differ only in consequence of difference in age, place of growth, or mode of desiccation. The colors are often so intermingled that it would be impossible to decide in which variety a particular specimen should be placed. The *brown* is the most abundant in the packages brought to our market. The *red*, besides the color of its epidermis, presents a rosy tint when broken, and is said to be somewhat more bitter than the preceding variety. The *gray* is much lighter-colored externally, usually rather larger, with less prominent rings and wider furrows, and is still more decidedly bitter. Ipecacuanha has been grown to some extent in India, without, however, being produced in commercial quantities. In the neighborhood of Johore (Straits Settlements) it is said to be cultivated with marked success. In 1887 some of the product found its way to the London markets under the name of *Indian ipecacuanha*. It is said to be commercially characterized by the presence of very large numbers of delicate rootlets, and, according to the analysis of Mr. Ransom, contained about $1\frac{7}{10}$ per cent. of the alkaloids. Of recent years it has not entered general commerce, probably on account of the high price which it commands in the neighborhood of Johore. Many years ago there was imported from Carácas into the United States a large gray ipecacuanha with badly marked rings. This variety disappeared for a time, but is probably the *Colombian* or *Carthagena Ipecacuanha* of modern commerce, which is distinguished from the Brazilian drug by being a little larger, with less conspicuous annuli and more marked medullary rays. Many years ago Lefort found that it contained rather less emetine than does Brazilian ipecacuanha, and the elaborate studies of Paul and Cownley have (*P. J. Tr.*, lvi.) shown that whilst the total alkaloidal strengths (2·10 to 2·65 per cent., Kebler, *A. J. P.*, 1896) of the two ipecacuanhas are about the same, the proportion of cephaëline is much larger and of emetine much smaller in the Carthagena drug than in the Brazilian. It is still uncertain what plant yields the Carthagena ipecacuanha, and consequently whether this root comes under the official definition of the Pharmacopœia. When the bark in either variety of ipecacuanha is opaque, with a dull amylaceous aspect, the root is less active. As the woody part is nearly inert, and much

point of flexion semicircular fissures, which give it some resemblance to the root of the Cephaëlis. It is often bifurcated at both extremities, and terminates at the top in a great number of small ligneous stalks. It is wrinkled longitudinally, and of a light yellowish-gray color. The bark is thin, and the interior ligneous portion very thick. The root has little taste or smell. According to Pelletier, 100 parts contain 5 of an emetic substance, 35 of gum, 1 of nitrogenous matter, and 37 of lignin. (*Histoire abrégée des Drogues simples*, i. 514.)

The root of a species of Ionidium growing in Quito has attracted some attention as a remedy in *elephantiasis*, under the South American name of *cuichunchulli*. The plant received from Dr. Bancroft the name of *I. marcucci*; but Sir W. Hooker found the specimen received from Dr. Bancroft to be the *I. parviflorum* of Ventenat. Lindley thinks a specimen he received under the same name from Quito to be the *I. microphyllum* of Humboldt. If useful in elephantiasis, it is so probably by its emeto-purgative action. (See *A. J. P.*, vii. 186.)

Under the name of *East Indian Ipecacuanha* there has appeared in the London markets a root of a pale pinkish-brown color, tapering rapidly from the base to the apex, and having annulations much closer than in the true ipecacuanha. It is especially distinguished from the latter root by being evidently monocotyledonous,—that is, without the central woody column,—the vascular bundles appearing under a pocket-lens as a more or less irregular ring of brownish dots. R. A. Cripp obtained from it a minute quantity of an alkaloidal substance, certainly distinct from the alkaloids of ipecacuanha. (*P. J. Tr.*, lv.). Ranwez and Campion have also described a false ipecacuanha derived from a monocotyledonous plant, *Cryptocoryne Spiralis*. (*Ann. d. Pharm.*, i.)

more difficult of pulverization than the cortical, it often happens that, when the root is powdered, the portion last remaining in the mortar possesses scarcely any emetic power; and care should be taken to provide against any defect from this cause.* The German Pharmacopœia provides for the rejection of the last fourth of the powder. The color of the powder is a light grayish fawn.† "When Ipecac is sound and free from mouldiness, its quality is proportionate to the thickness of the bark and the thinness of the ligneous portion."‡ *U. S.* Microscopically, ipecacuanha root is composed on the outside of a suberous layer of thick-walled cells; next, of parenchymatous tissue, five or six strata of irregular four-sided cells, which from without inward at first increase and then diminish in size. Raphides are in small numbers, but all the cells are gorged with starch granules, which are mostly compound, being composed of from two to eight or even more grains, which are muller-shaped, with one or two flat surfaces. The hilum is usually distinct, with two or three radiating crevices, sometimes scarcely apparent. The individual starch granules are 1.5 millimetres or less in diameter, the compound granules range from 7 to 19 millimetres in their longest diameter. The existence of swollen grains indicates the use of artificial heat in drying the roots. The liber is composed of much smaller cells, is irregular in thickness, and is rather full of starch. The cambium layer is formed of three or four series of colorless cells. The wood has its medullary rays very slightly marked, and contains only a few vessels, which are situated near the centre of the root.

Ipecacuanha has little smell in the aggregate state, but when powdered has a peculiar nauseous odor, which in some persons excites violent sneezing, in others dyspnœa resembling an attack of asthma. The taste is bitter, acrid, and very nauseous. Water and alcohol extract its virtues, which are injured by decoction. Its emetic property is supposed to reside in an alkaloid, called *emetine*, discovered by Pelletier in the year 1817. The cortical portion of ipecacuanha, analyzed by this chemist under the erroneous name of *Psychotria emetica*, yielded, in 100 parts, 16 of an impure salt of emetine, which was at first considered the pure emetic principle, 2 of an odorous fatty matter, 6 of wax, 10 of gum, 42 of starch, and 20 of lignin, with 4 parts loss, the woody portion of the root containing no alkaloid. According to the researches of A. R. L. Dohme (*A. J. P.*, 1895), the adherent stems contain from 15 to 20 per cent. less of the alkaloid than do the roots. Roots entirely conforming to the official requirements vary in alkaloidal strength from a little over 1 to over 2 per cent.: 1·80 per cent. probably is about the average yield. In addition to the alkaloids, Bucholz found extractive, sugar, and resin; and Erwin Williglk, afterwards, traces of a disagreeable-smelling volatile oil, phosphatic salts, and a peculiar acid, *ipecacuanhic acid*, which resembles caffeo-tannic and quinic acids, and has been shown by Reich (*Arch. der Pharm.*, [2] 113, 208) to be a glucoside, of the formula $C_{14}H_{18}O_7$. (See *A. J. P.*, xxiii. 352.) Good ipecacuanha has about 80 per cent. of cortical and 20 of ligneous matter. B. H. Paul and A. J. Cownley discovered that the alkaloid emetine is not homogeneous, but a mixture of two or more different substances. They have found an amorphous alkaloid associated with others which are distinctly crystalline, and very different from the amorphous alkaloid in physical characters.

The crystalline alkaloid is very much less soluble in ether, chloroform, or benzene than is the amorphous alkaloid with which it is associated; but, as is usual in such cases, it is not until separation has been carried to a considerable extent that this difference becomes apparent. The authors further seem to have obtained evidence that Carthagena ipecacuanha contains, in addition to a considerable amount of amorphous alkaloid, some proportion of another crystallizable alkaloid, which presents marked differences from the crystallizable alkaloid of Brazilian ipecacuanha. The authors are inclined to the conclusion that the percentage amount of alkaloid in ipecacuanha root does not vary very much from 3 per cent. (*P. J. Tr.*, 1893, 61.)

* For elaborately illustrated articles upon the microscopy of ipecacuanha and its adulterations, see Henry G. Greenish, *P. J. Tr.*, 1895, 685, and Albert Schneider, *Amer. Drug.*, 1897. According to Greenish, the distinctive characteristics of the powder of either Brazilian or Carthagena ipecacuanha are: (a) the form and size of the starch grains; (b) the absence of vessels, presence of perforated tracheides; (c) the acicular raphides; to these may be added (d) the emetine reaction with chlorine. The stem may in either case be distinguished from the root (in powder) by the presence (a) of sclerenchymatous cells; (b) of lignified cells of the pith; (c) of spiral vessels. The Carthagena ipecacuanha can usually be distinguished by the great size of its starch grains, although there are some Carthagena roots that contain small granules of starch.

† Attempts have been made to adulterate powdered ipecacuanha with the powder of almonds; but the fraud is readily detected by forming a paste with a little water and putting it into a hot place for half an hour, when, if the ipecacuanha be pure, only its own odor will be perceived, but, if adulterated, a decided odor of almonds will be noticed. (*Journ. de Pharm.*, Juin, 1874, 479.)

‡ See paper by Dr. A. R. L. Dohme, *Proc. A. P. A.*, 1893, 172; 1894, 233.

A. R. L. Dohme obtained a little over 2 per cent. of the alkaloid. (*A. J. P.*, 1895.) In a later article (*A. J. P.*, 1895, 256) Paul and Cownley present additional results. They give to the amorphous alkaloid the name *emetine*, and find it to have the formula $C_{15}H_{22}NO_2$ and the melting point 68° C. The crystalline alkaloid accompanying it in the Brazilian ipecacuanha they call *cephaëline*, and give it the formula $C_{14}H_{20}NO_2$ and the melting point 102° C. According to this, emetine is *methyl-cephaëline*. The third alkaloid found by them melts at 138° C., and apparently has a much higher molecular weight than emetine or cephaëline. This alkaloid and its salts, which are uncrystallizable, are rapidly decomposed on exposure to light; in this respect differing from emetine and cephaëline, both of which are unaffected by light.

Various processes have been published for the isolation of emetine, and these will be found in previous editions of this work (see U. S. D., 17th ed., 752); but, in view of the researches above quoted, none yield pure emetine. The results of Paul and Cownley's researches (1899) are summarized below. W. G. Whiffen patented in Germany in 1898 a process for making emetine, basing it on the separation of emetine hydrobromide from extract of ipecac; cephaëline hydrobromide crystallizes with great difficulty, whilst emetine hydrobromide is easily crystallized and separated. (*Chem. and Drug.*, 1898, 694.)

Emetine ($C_{15}H_{22}NO_2$) is an amorphous white powder; melting point 68° C. It forms crystalline salts with the halogens and nitric acid; dissolves readily in chloroform, ether, benzol, or alcohol, its alcoholic solution giving no coloration with ferric chloride. It is insoluble in solutions of caustic or carbonated alkalies, but easily dissolved in diluted acetic acid. Glacial acetic acid dissolves emetine without effecting substitution. From the acetic acid solution, potassium hydrate precipitates a white, flocculent precipitate, insoluble in excess, but readily soluble in ether.

Cephaëline ($C_{14}H_{20}NO_2$) is crystalline, occurring in white, silky needles; melting point, 96·9° C. Its salts are not crystalline. It dissolves easily in ether, benzol, chloroform, or alcohol. Ferric chloride added in small quantity to an alcoholic solution produces a dark reddish-brown coloration; this is believed to be due to the presence of phenol-hydroxyl. Cephaëline dissolves easily in solution of potassium hydrate, and is not extracted by ether; it is easily soluble in acetic acid, and is reprecipitated by the cautious addition of potassium hydrate as a white precipitate which is soluble in excess of the alkali. It is upon the peculiar behavior of cephaëline with caustic alkali and ether that the separation of cephaëline and emetine depends. Dr. Hesse assigns to emetine the formula $C_{30}H_{42}N_2O_4$, and to cephaëline $C_{28}H_{38}N_2O_4$. A third alkaloid has been isolated by Paul and Cownley (*P. J. Tr.*, 1895); it exists in a very small quantity in the root.

Emetine hydrobromide ($C_{15}H_{22}NO_2.HBr.9H_2O$), which is suggested as the most convenient salt of emetine for medicinal use, is permanent, occurring in white, silky needles, readily soluble in water, difficultly soluble in absolute alcohol or chloroform.

Professor Flückiger (*Pharm. Zeitung*, 1886, p. 30) gives a process for assaying ipecacuanha, which consists in exhausting 10 to 15 grammes of the drug in very fine powder with boiling chloroform to which a drop of solution of ammonia has been added; the extraction is continued until the chloroform passing through shows no sign of alkaloid when treated with acidulated water. Upon distilling off the chloroform, the emetine is left in a very pure condition, and may be dried at 100° C. and weighed, or perhaps more conveniently titrated with Mayer's reagent. He found the average quantity of emetine in ipecacuanha root not to exceed 1 per cent. (*P. J. Tr.*, 1886, 643.) H. W. Jones approves of this method, and modifies it by treating the residue from the chloroformic solution with water and dilute sulphuric acid, filtering, and recovering the alkaloid by means of chloroform and ammonia. (*P. J. Tr.*, 1886, p. 277.) For other methods see a paper by Dr. A. B. Lyons, *A. J. P.*, 1885, pp. 531, 542.

Medical Properties and Uses. Ipecacuanha is in large doses emetic, in smaller doses diaphoretic and expectorant, and in still smaller, stimulant to the stomach, exciting appetite and facilitating digestion. In quantities not quite sufficient to vomit, it produces nausea, and frequently acts on the bowels. As an emetic, it is mild but tolerably certain, and, being free from corrosive or narcotic properties and usually thrown from the stomach by one or two efforts, never produces dangerous effects. It was employed as an emetic by the natives of Brazil when that country was first settled by the Portuguese; but, though described in the work of Pison, it was not known in Europe till 1672, and did not come into use till some years afterwards. John Helvetius, grandfather of the famous author of that name, having been associated with a merchant who had imported a large quantity of ipecacuanha into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections that general atten-

tion was drawn to it, and the fortunate physician received from Louis XIV. a large sum of money and public honors on the condition that he should make it public. As an emetic, ipecacuanha is peculiarly adapted, by its mildness and efficiency, to cases in which the object is merely to evacuate the stomach, or where a gentle impression only is desired; and in most other cases in which emetics are indicated it may be advantageously combined with the more energetic medicines, which it renders safer by insuring their discharge. It is especially useful where narcotic poisons have been swallowed, as, under these circumstances, it may be given in almost indefinite doses, with little comparative risk of injury. In tropical or typhoid *dysentery* it is of very great value. As a nauseating remedy it is used in *croup*, and as a diaphoretic combined with opium, in numerous diseases. (See *Pulvis Ipecacuanhæ et Opii*.) Its expectorant properties render it useful in *acute bronchitis*. It has been given, also, with supposed advantage, in very minute doses, in *dyspepsia*, and in chronic disease of the gastro-intestinal mucous membrane, and as an anti-emetic. It has been found especially useful in *winter coughs* and *asthmatic catarrh*, inhaled in the form of spray; the wine of ipecacuanha being the preparation used.* Ipecacuanha is most conveniently administered, as an emetic, in the form of powder suspended in water. The dose is about twenty grains (1·3 Gm.), repeated, if necessary, at intervals of twenty minutes till it operates. In some persons much smaller quantities prove emetic, and we have known an individual who was generally vomited by the fraction of a grain. The operation may be facilitated, and rendered milder, by draughts of warm water or warm chamomile tea. For the production of nausea, the dose in substance may be two grains (0·13 Gm.), repeated more or less frequently according to circumstances. As a diaphoretic it may be given in the quantity of a grain (0·065 Gm.); as an alterative, in diseases of the stomach and bowels, in that of one-quarter or one-half grain (0·016–0·03 Gm.) two or three times a day.

According to the experiments of Dr. Robert B. Wild (*London Lancet*, ii., 1895), both cephaëline and emetine are powerful emetics,† which lower the arterial pressure by depressing the heart; they are also said to be muscle poisons, and to act directly upon the muscular coats of the blood-vessels. As an emetic, cephaëline was found to be twice as strong as emetine; but the emetic dose of it did not produce as much general depression as did that of emetine. On account of the violence of their action, these alkaloids are, however, inferior as practical remedies to ipecacuanha, and if given in overdoses may produce dangerous and even fatal consequences. The dose of impure emetine is about a grain (0·065 Gm.), of the pure not more than an eighth of a grain (0·008 Gm.), repeated at proper intervals till it vomits. In proportional doses, it may be applied to the other purposes for which ipecacuanha is used. It will excite vomiting when applied to a blistered surface after the removal of the cuticle. Wild gives one-fourth of a grain of emetine and from one-twelfth to one-sixth of a grain of cephaëline as the proper emetic dose.

An ointment made with one part of powdered ipecacuanha, one of olive oil, and two of lard, rubbed once or twice a day for a few minutes upon the skin, produces a copious and very permanent eruption, but is at present only very rarely employed as a counter-irritant.

IRIS. U. S. Iris. [Blue Flag.]

(Ī'RĬS.)

"The rhizome and rootlets of Iris versicolor, Linné (nat. ord. Irideæ)." *U. S.*

Rhizome d'Iris varié, Glaïeul bleu, *Fr.*; Verschiedenfarbige Schwertlilie, *G.*

Gen. Ch. Corolla six-parted; the alternate segments reflected. *Stigmas* petal-shaped. *Willd.*

In all the species belonging to this genus, so far as examined, the roots are more or less acrid, and possessed of cathartic and emetic properties. In Europe, *Iris fœtidissima*, *I. florentina*, *I. germanica*, *I. pseudo-acorus*, and *I. tuberosa* have at various times been admitted into use, and the unpeeled roots of *I. germanica* are still sold in the Indian bazaars under the name of *Irisia*.

Iris versicolor. Willd. *Sp. Plant.* i. 233; Bigelow, *Am. Med. Bot.* i. 155. This indigenous species of Iris has a perennial, fleshy, horizontal, fibrous root or rhizome, and a stem two or three feet high, round on one side, acute on the other, and frequently branching. The leaves are sheathed at the base, sword-shaped, and striated. The flowers are from two to six in number, and are usually blue or purple, though varying much in color. The capsule has three

* Sydney Ringer, M.D., and Wm. Murrell, *Lancet*, Sept. 5, 1874, 328.

† These experiments, taken with those of Paul and Cownley, indicate that whilst for many therapeutic purposes Carthagena ipecacuanha is superior rather than inferior to the Brazilian variety, it is too slow in its action for use as an emetic in cases of poisoning.

valves, is divided into three cells, and when mature is oblong, three-sided, with obtuse angles, and contains numerous flat seeds. The blue flag is found in all parts of the United States, flourishing in low wet places, in meadows, and on the borders of swamps, which it serves to adorn with its large and beautiful flowers. These make their appearance in June. The root is the medicinal portion. The flowers afford a fine blue infusion, which serves as a test for acids and alkalies.

Properties. The recent root is without odor, and has a nauseous, acrid taste, which is imparted to water by decoction, and still more perfectly to alcohol. The acrimony as well as medicinal activity is impaired by age. If cut when fresh into slices, dried at the temperature of about 100° F., then powdered and kept in bottles excluded from the air, the root retains its virtues unimpaired for a considerable time. (*Andrews.*) It is officially described as follows: "Rhizome of horizontal growth, consisting of joints, 5 to 10 Cm. long, cylindrical in the lower half, flattish near the upper extremity, and terminated by a circular scar, annulated from the leaf-sheaths, grayish-brown; roots long, simple, crowded near the broad end; odor slight; taste acrid and nauseous." *U. S.* D. W. Cressler found in this plant starch, gum, tannin, sugar, an acid resin, fixed oil, and indications of an alkaloid. (*A. J. P.*, 1881, p. 602.)

Blue flag possesses the cathartic, emetic, and diuretic properties common to most of its congeners. It was said by Mr. Bartram to be much esteemed by the southern Indians; and Dr. Bigelow states that he has found it efficacious as a purgative, though inconvenient from the distressing nausea and prostration which it is apt to occasion; but other practitioners have employed it with less unpleasant effects. It may be given in substance, decoction, or tincture. The dose of the dried root is from ten to twenty grains (0·65–1·3 Gm.). Under the unscientific name of *iridin* or *irisin*, which should be reserved for the pure active principle when discovered, the "Eclectics" have for some time used an oleoresin, obtained by precipitating a tincture of the root with water, and mixing the precipitate with an equal weight of some absorbent powder, for which purpose powdered liquorice root would probably answer well. Wm. E. Jenks (*A. J. P.*, 1881, p. 601) prepares the *oleoresin of iris* by exhausting the root with alcohol sp. gr. ·835, and distilling off the alcohol. See also paper on the constituents of the *oleoresin* by W. L. Cliffe, *A. J. P.*, 1884, p. 616. The so-called irisin is undoubtedly purgative, and is believed by some practitioners to have a very decided action upon the liver,—a belief which is confirmed by the researches of Prof. Rutherford, who proved that in dogs it is a powerful stimulant to the liver and has also a decided influence upon the intestinal glands; he ranks it as less irritant to the intestines than podophyllin, and more purgative than euonymin. It may be given in pill in the dose of from three to four grains (0·20–0·26 Gm.).

JALAPA. U. S., Br. Jalap.

(JĄ-LĀ'PĄ.)

"The tuberous root of Ipomœa Jalapa, Nuttall (nat. ord. Convolvulaceæ)." *U. S.* "The dried tubercules of Ipomœa Purga, Hayne." *Br.*

Tuber Jalapæ, *P. G.;* Radix Jalapæ; Jalap, *Fr.;* Jalape, Jalapenknollen, Jalapenwurzel, *G.;* Sciarappa, *It.;* Jalapa, *Sp.*

The precise botanical origin of jalap remained long unknown. It was at first ascribed by Linnæus to a Mirabilis, and afterwards to a new species of Convolvulus, to which he gave the name of *C. jalapa*. The correctness of the latter reference was generally admitted; and, as the *Ipomœa macrorrhiza* of Michaux, growing in Florida and Georgia, was believed to be identical with the *C. jalapa* of Linnæus, it was thought that this valuable drug, which had been obtained exclusively from Mexico, might be collected within the limits of the United States. But the error of this opinion was soon demonstrated. Dr. John R. Coxe, of Philadelphia, received living roots of jalap from Mexico in 1827, and succeeded in producing a perfect flowering plant, of which a description, by Mr. Nuttall, was published in the *Am. Journ. of Med. Sci.* for January, 1830. The same plant has since been cultivated in various parts of Europe,* and has been introduced into the Neilgherry Hills of India, where it grows vigorously. J. H. Balfour (*Curtis's Bot. Mag.*, Feb. 1847) maintains that the plant belongs to the genus Exogonium of Choisy, as defined in De Candolle's *Prodromus*, being distinguished from Ipomœa by its exserted stamens. Bentham and Hooker, however, do not acknowledge the validity of the various genera into which Ipomœa has been broken up by Choisy (*Genera Plantarum*, ii.). Engler and Prantl

* The jalap grows freely in the south of England, but the season is too short for the production of seed by it, although the root has yielded 11·97 per cent. of resin. (*P. J. Tr.*, Feb. 1869.)

have restored the genus Exogonium [*E. Purga* (Wender.) Benth.] for the plant yielding jalap.

Exogonium purga. Balfour, *Curtis's Bot. Mag.*, 3d ser., vol. iii. tab. 4280; *B. & T.* 186.—*Ipomœa jalapa.* Nuttall. Carson, *Illust. of Med. Bot.* ii. 13, pl. 61.—*Ipomœa purga.* Hayne, *Darstell. und Beschreib.*, etc., xii. 33 and 34; Lindley, *Flor. Med.* 396. The root of this plant is a roundish somewhat pear-shaped tuber, externally blackish, internally white, with long fibres proceeding from its lower part, as well as from the upper rootstalks. A tuber produced by Dr. Coxe was, in its third year, between two and three inches in diameter. The stem is round, smooth, much disposed to twist, and rises to a considerable height upon neighboring objects, about which it twines. The leaves are heart-shaped, entire, smooth, pointed, deeply sinuated at the base, prominently veined on their under surface, and supported upon long footstalks. The lower leaves are nearly hastate, or with diverging angular points. The flowers, which are large and of a lilac-purple color, stand upon peduncles about as long as the petioles. Each peduncle supports two or, more rarely, three flowers. The calyx is without bracts, five-leaved, obtuse, with two of the divisions external. The corolla is funnel-form. The stamens are five in number, with oblong, white, somewhat exserted anthers. The stigma is simple and capitate.

Section of a fragment of jalap tuber, showing raphides and starch in cells.

The jalap-plant is a native of Mexico, where it is dug during the whole year, and mostly dried over the hearths of the Indian huts. It derives its name from the city of Jalapa, in the state of Vera Cruz, in the neighborhood of which it grows, at the height of about 6000 feet above the ocean. The drug is brought from the port of Vera Cruz in bags containing usually between 100 and 200 pounds.* The jalap plant is now successfully cultivated in the government cinchona plantations in India. Analyses of the Indian tubers show that when grown on fresh soil they contain from 16 to 17 per cent. of resin, and that by manuring the percentage is notably increased, even to 22 per cent. For an account of the cultivation of jalap in Madras, see *Amer. Drug.*, 1896, 127.

Properties. The tuber comes either whole, or divided longitudinally into two parts, or in transverse circular slices. The entire tubers are irregularly roundish, or ovate and pointed, or pear-shaped, usually much smaller than the fist, and the larger ones marked with circular or vertical incisions, made to facilitate their drying. The root is preferred in this state, as it is less apt to be defective and is more easily distinguished from the adulterations than when sliced. A much larger proportion comes entire than formerly, indicating a greater scarcity of the older roots, which it is necessary to slice in order to dry them properly. The tuber is heavy, compact, hard, brittle, with a shining undulated fracture, not fibrous, but exhibiting irregular dark concentric lines, and, when examined under the microscope, numerous compound starch grains, clustered crystals of calcium oxalate, and cells containing resin (resinous points when viewed under a low magnifying power). Externally the tuber is brown and wrinkled, internally of a grayish color, diversified by concentric darker circles, in which the matter is denser and harder than in the intervening spaces. Jalap is always kept by pharmacists in the state of powder, which is of a yellowish-gray color, and when inhaled irritates the nostrils and throat, and provokes sneezing and coughing. The odor of the root, when cut or broken, is heavy, sweetish, and rather nauseous; the taste is sweetish, somewhat acrid, and disagreeable. It yields its active properties partly to water, partly to alcohol, and completely to diluted alcohol, and the U. S. P. gives the following test of its efficiency: "On exhausting 100 parts of Jalap with alcohol, concentrating the tincture to 40 parts, and pouring it into water, a precipitate of resin should be obtained, which, when washed with water, and dried, should weigh not less than 12 parts, and of which not over 10 per cent. should be soluble in ether."

There can be no doubt that much of the commercial jalap is far below the official standard. In June, 1888, a series of analyses yielded to Dr. Squibb, in New York, only about 8 per cent., and the same chemist in 1889, as the result of applications made in Hamburg,

* The root of *I. pandurata*, *Man Root*, *Man of the Earth*, of this country, is sometimes met with in American commerce. Mr. C. Manz found a resin in it. (*A. J. P.*, 1881, 384.)

London, and New York, for the finest jalap, obtained only one consignment yielding more than 7·5 per cent. Dr. Squibb has indeed found jalap tubers yielding only 1·8 per cent. of resin. (*A. J. P.*, 1868.) These analyses, it is true, are contrary to the results of R. A. Cripps (*P. J. Tr.*, xix., 1888), who found numerous specimens of jalap in the London market ranging 10 per cent. and over; but they are in accord with those of T. P. Suess (*A. J. P.*, 1890), and there seems to be little doubt that jalap has greatly decreased in quality of late years. Further, as 20 per cent. of resin does not seem to be an extraordinary yield of properly grown roots, the belief of Prof. Flückiger, that jalap resin is extracted from the roots in Mexico before the latter are thrown into commerce, seems probable.* "Jalap, when assayed by the process described under 'Jalapæ Resina,' should yield not less than 9 nor more than 11 per cent. of resin having the properties of the official resin." *Br.* For Alcock's method of assay, see *A. J. P.*, 1892, 533.

M. Cadet de Gassicourt obtained from 500 parts of jalap, 24 of water, 50 of resin, 220 of gummy extract, 12·5 of fecula, 12·5 of albumen, 145 of lignin, 16·3 of saline matters, and 2·7 of silica, with a loss of 17 parts. Buchner and Herberger supposed that they had discovered a basic substance, which they called *jalapin*. G. A. Kayser found that the resin of jalap consists of two portions, one of which, amounting to seven parts out of ten, is hard and insoluble in ether, the other is soft and soluble in that menstruum. The hard resin he named *rhodeoretin*, and found to be identical with the jalapin of Buchner and Herberger. By reaction with the alkalies it is converted into an acid, called *rhodeoretinic acid*. Rhodeoretin is slightly soluble in water, freely so in alcohol, and insoluble in ether, chloroform, or benzene; and the alcoholic solution is precipitated both by ether and water. It is dissolved by solutions of the alkalies, more quickly if heated, and is not precipitated by acids, having become soluble by conversion into the acid above referred to. It purges violently in the dose of three or four grains, and is supposed to be the active principle of jalap. Mayer confirmed and extended the observations of Kayser. He gave the name of *convolvulin* to Kayser's rhodeoretin, and announced its formula as $C_{31}H_{50}O_{16}$. This substance is colorless when pure, dissolving easily in ammonia, and is not reprecipitated by acids, because of its conversion into *convolvulic acid*, which is a hydrate of the glucoside convolvulin. This, on being treated with nitric acid, yields *sebacic acid*. Convolvulin possesses in a high degree the purgative properties of jalap. Mayer obtained from *Ipomœa orizabensis* a resin which he called *jalapin*, which was afterwards shown by Mr. Keller to be identical with the resin of scammony. Mayer's jalapin differs from convolvulin in being soluble in ether. The formula of jalapin, according to Dr. Samuelson, is $C_{34}H_{56}O_{16}$, which would show it to be a homologue of convolvulin, $C_{31}H_{50}O_{16}$. Poleck (*A. J. P.*, 1892, p. 465) has continued the investigation of the jalapin from *I. orizabensis*, and confirms the identity of it with scammonin, giving it the formula $C_{34}H_{56}O_{3}$. He suggests that the name of jalapin, which is misleading, should be replaced by *orizabin*. To *jalapic acid* he gives the formula $H_2C_{17}H_{28}O_9$, and to *jalapinolic acid* $HC_{16}H_{29}O_3$. A. Kromer (*Pharm. Ztsch. f. Russl.*, 1894, Nos. 1–7) has made a study of convolvulin. He finds it to be lævogyre, and gives it the formula $C_{61}H_{108}O_{27}$, which is deduced from its analysis and decomposition products; alkalies decompose it into one molecule of volatile *methylethyl-acetic acid*, $C_5H_{10}O_2$, and two molecules of monobasic *convolvulinic acid*, $C_{28}H_{52}O_{14}$. This is amorphous, yielding a white hygroscopic powder soluble in water and alcohol, insoluble in ether; strong sulphuric acid colors it red or brown-red; by the action of acids one molecule of convolvulinic acid yields two molecules of a glucose and one molecule of convolvulinolic acid, $C_{16}H_{30}O_3$, which is insoluble in water, melts at 46° C., is not colored by sulphuric acid, and is isomeric with jalapinolic acid and scammonolic acid, both of which melt at from 63°–64° C. A. F. Stevenson (*N. R.*, 1879, 359) has studied the two resins found in jalap, and furnishes a tabular statement of the differences be-

* The poor quality of Mexican jalap makes the question of the possibility of the cultivation of the plant important. In 1834, Widnmann, an apothecary of Munich, showed that in the gardens of Munich the jalap plant would grow and produce tubers yielding as high as 22 per cent. of resin. His results have been confirmed, especially by Clamor Marquart, at Bonn. In England, jalap yielding nearly 12 per cent. of resin has been successfully grown. (*P. J. Tr.*, Feb. 1869.) There seems to be no doubt that the jalap plant will flourish in a temperate climate. It is a question whether the medicinal results are not better in temperate than in hot climates. Thus, M. Warden (*P. J. Tr.*, Aug. 1887) found tubers produced in Northwestern India to be somewhat below the standard.

The question as to possible substitutes for the official species is also growing in importance. Prof. Flückiger has pointed out that the seeds of the *Ipomœa hederacea* (*Kaladana seeds*) yield very readily 8 per cent. of resin identical with that obtained from *Ipomœa purga*. As this plant is very abundant in India, it would appear to be a possible commercial source for jalap resin. Prof. Shimoyama, of Tokio, has shown that jalap resin can also be obtained from the *Ipomœa triloba* (*Pharbitis triloba*) of Japan. M. K. Hyrano confirms this, and states that the seeds of the plant have long been used in Japan, under the name of "*kengashi*." (For details, and method of extracting the resin, see *P. J. Tr.*, Oct. 1888.)

tween the soft resin jalapin and the hard resin convolvulin, which we give in a foot-note.* The proportion of resin to the other ingredients of the root varies considerably in different specimens. According to Gerber, the root contains 7·8 per cent. of hard resin, 3·2 of soft resin, 17·9 of extractive, 14·5 of gummy extract, 8·2 of a coloring substance which becomes red under the influence of the alkaline carbonates, 1·9 of uncrystallizable sugar, 15·6 of gum mixed with some saline matters, 3·2 of bassorin, 3·9 of albumen, 6·0 of starch, and 8·2 of lignin, with some water, and various salts. For the method of obtaining the resin of jalap pure, see *Resina Jalapæ.*

Jalap is apt to be attacked by worms, which, however, are said to devour the amylaceous or softer parts, and to leave the resin, so that the worm-eaten drug is more powerfully purgative than that which is sound. Thus, out of 397 parts of the former, M. Henry obtained 72 parts of resin, while from an equal quantity of the latter he procured only 48 parts. Hence worm-eaten jalap should be employed for obtaining the resin, but should not be pulverized, as it would afford a powder of more than the proper strength. The drug is also liable to various adulterations, or fraudulent substitutions, which, however, can usually be detected without difficulty. Those which have attracted particular attention are mentioned in the note below.†

*1. *Solvents.*

Solvent.	Jalapin.	Convolvulin.
Chloroform.	Readily soluble.	Slightly soluble.
Ether.	Very soluble.	Insoluble.
Petrol. naphtha.	Slightly soluble.	Insoluble.
Oil of turpentine.	Slightly soluble.	Insoluble.
Benzene.	Slightly soluble.	Insoluble.
Carbon disulph.	Easily soluble.	Insoluble.
Water.	Slightly soluble.	Slightly soluble.
Hydrochloric acid.	Slightly soluble.	Readily soluble.
Sulphuric acid.	Very soluble, with production of maroon color, changing to black.	Readily soluble, with production of bright red coloration.
Caustic potassa.	Easily soluble.	Easily soluble, with production of odor of whiskey when heated.
Ammonia.	Readily soluble, more so than convolvulin.	Slightly soluble.

2. *Reactions with Oxidizing Agents on convolvulin and jalapin dissolved in concentrated sulphuric acid.*

Agent.	Jalapin.	Convolvulin.
Potassium bichromate.	Produces odor of rancid butter and reddish brown color.	Produces odor of rancid butter and olive-green color.
Potassium permanganate.	Same reactions.	Same reactions.
Potassium nitrate.	Same reactions, but not so strong.	Same reactions.
Potassium chlorate.	Same reactions, but not so strong.	Same reactions.
Manganese dioxide.	Same odor, and color dark green.	Same odor, and color rose-pink.

† *Tampico Jalap.* (*Purga de Sierra Gorda*, Mexican.) This drug closely resembles in appearance, odor, and taste the true jalap, but the tubers are somewhat smaller, more elongated and shrivelled. According to Mr. Ambrose Andouard, it is the *jalap digité majeur* of M. Guibourt. Through the efforts of Mr. Daniel Hanbury, of London, aided by two Prussian officials in Mexico, Mr. Hugo Finck, vice-consul at Cordova, and Mr. E. Bonecke, consul-general at Mexico, the origin of the drug was traced to the state of Guanajuato, where it grows along the Sierra Gorda, near San Luis de la Paz. In this place it is purchased from the Indians, and conveyed by mules to Tampico, where it enters into commerce. Through the agency of the same gentlemen, Mr. Hanbury, after some failures, succeeded in obtaining a living tuber, from which he raised a flourishing plant that proved to be an undescribed species of the genus *Ipomœa*, differing from *I. purga* by its bell-shaped corolla and pendulous flower-buds. To it Mr. Hanbury gave the name *I. simulans.* (*A. J. P.*, July, 1870.) Prof. H. Spirgatis, of Königsberg, obtained a resin by preparing a tincture of the Tampico jalap, evaporating, washing, boiling the residue in water, redissolving in alcohol, and decolorizing by charcoal. He gave it the name of *tampicin.* Its physical properties are similar to those of the jalap resin. It is brittle, tasteless, inodorous, insoluble in water, soluble in ether and alcohol, and in solution has a feeble acid reaction. By strong alkalies it is changed into a soluble acid which Prof. Spirgatis calls *tampicic acid.* By the action of dilute sulphuric, nitric, or hydrochloric acid, it is converted, slowly if cold, but rapidly with heat, into a peculiar acid called *tampicolic*, with sugar. For the mode of preparing these acids, and their properties, the reader is referred to an article in *N. R.*, July, 1871, p. 50. The melting point of tampicin is 130° C.; its formula is $C_{34}H_{54}O_{14}$. The percentage of it yielded by the drug varies from a minimum of 10 per cent. (Hanbury) to a maximum of 15 per cent. (Umney). Andouard states that it is purgative.

According to Prof. Herlant, even in powder it is easy to detect the presence of the root of *Mirabilis jalapi*, which is sometimes used as an adulterant to jalap, by the presence of acicular raphides (calcium oxalate). Tampico jalap can also be distinguished from the Vera Cruz variety by the microscope. In Tampico jalap the starch is arranged in little compact masses in the cell, whilst in Vera Cruz jalap the starch occurs in grains irregularly united, or isolated and much larger than those of the Tampico variety. The agglomerated masses of resin in the Tampico jalap are smaller than in the Vera Cruz jalap.

Mechoacan. Jalap is said to be sometimes adulterated with *bryonia root*; but no instance of the kind has come

Jalap should be rejected when it is light, of a whitish color internally, of a dull fracture, spongy, or friable. Powders of calomel and jalap, taken on long voyages to southern climates, are said, when brought back, to have become consolidated, and so far chemically altered as plainly to exhibit globules of mercury. This change is ascribed by Schacht and Wackenroder

under our notice; and the two drugs are so widely different that the fraud should be instantly detected. (See *Bryonia.*) It is probable, however, that the adulteration which has been considered as bryonia root is the *mechoacan,* which in Europe is sometimes called American bryony and was formerly erroneously supposed to be derived from a species of Bryonia. Mechoacan is a product of Mexico, which was taken to Europe even before the introduction of jalap. The plant producing it has been conjectured to be *Ipomœa macrorrhiza* of Michaux, which is believed to grow in Mexico near Vera Cruz, as well as in our Southern States, and the root of which is said to weigh, when of full size, from fifty to sixty pounds, and, according to Dr. Baldwin, has little or no purgative power. But this origin is quite uncertain: Guibourt states that the mechoacan of Europe is the product of *Asclepias contrayerva.* (*Journ. de Pharm. et de Chim.,* iv. 1866.) Mechoacan is in circular slices, or fragments of various shapes, white and farinaceous within, and, as found in the European markets, generally destitute of bark, of which, however, portions of a yellowish color sometimes continue to adhere. The larger slices are sometimes marked with faint concentric striæ; and upon the exterior surface are brown spots and ligneous points, left by the radicles after removal. (*Guibourt.*) Though tasteless when first taken into the mouth, it becomes after a time slightly acrid. It is very feebly purgative. We have seen flat circular pieces of root, mixed with jalap, altogether answering this description, except that the cortical portion still remained, between which and the starchy parenchyma there was an evident line of division.

Orizaba Root. Male Jalap. Light, Woody, or *Fusiform Jalap. Jalap Stalks. Purgo Macho* (Mexican). This is the product of a plant named by M. Ledanois *Convolvulus orizabensis,* from the city of Orizaba, in the neighborhood of which it grows abundantly. A description of it was first published in this country by Mr. D. B. Smith, in a paper in *A. J. P.* (ii. 22). For an account of the plant the reader is referred to the same journal (x. 224). The recent root is large, spindle-shaped, sometimes twenty inches in length, branched at its lower extremity, yellow on its outer surface, and white and milky within. The drug, as described by Guibourt, is in circular pieces, two or three inches in diameter, or in longer and more slender sections. As we have seen it, the shape of the pieces is often such as to indicate that the root has been sliced transversely and each circular slice divided vertically into quarters. The horizontal cut surface is dark from exposure, unequal from the greater shrinking in desiccation of some parts than others, and presents the extremities of numerous fibres, which are often concentrically arranged, and run in the longitudinal direction of the root. Internally the color is grayish, and the texture, though much less compact than that of jalap, is sometimes almost ligneous. The taste is at first slight, but after a time becomes somewhat acrid and nauseous. It has cathartic properties similar to those of the true jalap, but feebler, requiring to be given in a dose of from thirty to sixty grains in order to operate effectively. (*Journ. de Pharm.,* xxiv. 166.) The resin of *C. orizabensis,* which has been unfortunately named *jalapin* by Meyer, is, according to that chemist, changed by boiling with baryta water into an acid called *jalapic acid;* and both jalapin and jalapic acid are glucosides, being resolved by boiling dilute acid into glucose, and a peculiar substance which he designates as *jalapinol.* (See *Journ. de Pharm.,* 3e sér., xxix. 123.) It differs from jalap resin in consisting of only one principle, which is entirely soluble in ether. But both resins are distinguished from all others by being gradually dissolved in concentrated sulphuric acid, and deposited again after some hours in a soft state. (*Chem. Gaz.,* No. 53; from Liebig's *Annalen.*) Its formula is $C_{34}H_{56}O_{16}$, and it is homologous with convolvulin, or true jalap resin. Samuelson (*Inaug. Diss.,* Breslau, 1883), who has made a study of it, considers it to be the anhydride of the dibasic jalapic acid, $2C_{17}H_{30}O_9 - 2H_2O = C_{34}H_{56}O_{16}$. He gives to jalapic acid the formula $C_{17}H_{30}O_9$, and states that it is formed from the jalapin by the action of alkalies. Jalapinol, $C_{16}H_{30}O_3 + 1\frac{1}{2}H_2O$, he says is an aldehyde, as it reduces ammoniacal silver solution, and yields a crystalline compound with acid potassium sulphite. Potassium permanganate oxidizes jalapinol to jalapinolic acid, $C_{16}H_{30}O_4$. Hanbury and Flückiger obtained 11·8 per cent. of it from the root, and state that it is probably the jalapin of English pharmacy. It is considered by chemists identical with the resin of scammony, and is affirmed to have similar drastic properties. These results were confirmed by Poleck (*loc. cit.*), except that jalapinol could not be obtained.

Rose-scented Jalap. Overgrown Jalap. A false jalap was some years since brought into market, imported from Mexico into New York in considerable quantities, and was offered for sale under the name of *overgrown jalap.* A specimen brought to Philadelphia and examined by a committee of the College of Pharmacy presented the following characters. It was in light, entire or vertically sliced tubers, of different forms and magnitudes, spindle-shaped, ovate and kidney-form, some as much as six inches long and three thick, others much smaller, externally somewhat wrinkled, with broad, flattish, light-brown ridges, and shallow darker furrows, internally grayish white, with distant darker concentric circles, sometimes uniformly amylaceous, of a dull rough fracture, a loose texture, a slight, peculiar, and sweetish odor, and a feeble jalap-like taste. The powder was of a light-gray color, and did not irritate the nostrils or throat during pulverization. The root differed from mechoacan by the absence of the marks of rootlets, and from male jalap by the want of a fibrous structure. It yielded by analysis, in 100 parts, 3 of a soft and 4 of a hard and brittle resin, 17 of gummy extractive, 28 of starch and inulin, 10 of gum and albumen, 23·2 of lignin, and 14·8 of saccharine matter and salts of lime, including loss. In doses of from fifteen to twenty grains it produced no effect on the system. A similar root was described by Guibourt by the name of *rose-scented jalap.* It was taken to France from Mexico, mixed with genuine jalap. It proved equally inefficacious as a purgative, and probably had the same origin. This spurious drug is probably the product of a Convolvulus or Ipomœa. (See *A. J. P.,* xiv. 289.)

Two varieties of false jalap, imported into New York, are described by Mr. John H. Currie in the *N. Y. Journ. of Pharm.* for Jan. 1852. The first corresponds with the root above described as that of *Convolvulus orizabensis,* or *male jalap,* both in appearance and in the character of its resinous ingredient. The second is a tuberous root, resembling, in shape, color, and size, the butternut, or fruit of *Juglans cinerea,* being black or nearly so externally, dull over most of the surface but glossy in spots, with deep longitudinal incisions, internally yellow or yellowish white, with a horny fracture, and upon the transversely cut surface marked with sparse dots, as if from delicate fibres. It contains no resin, and appears to be inert.

In the *Journal de Pharmacie* (Dec. 1863, p. 477, and March, 1864, p. 212) three other tubers are described by M. Guibourt which have been offered in the market for jalap,—one named *false jalap of New Orleans,* because imported into France from that city, the second *digitate jalap* (*jalap digité*), from the arrangement of its component tubers, and the third *radiated false jalap* (*faux-jalap rayonné*), from the stellate appearance of the cut surface. These jalaps do not closely resemble in physical properties the true root.

Another false jalap, some tubers of which were exhibited to Prof. Procter by Mexicans, who stated that they were

to a fungous growth. (*Arch. der Pharm.*, xxxix. 239.) The best criterion of good quality in jalap is the proportion of its resinous constituent; and all specimens intended for use in the powdered form, or in any liquid preparation, should be rejected if they contain less than 12 per cent. of resin.

Medical Properties and Uses. Jalap is an active cathartic, operating briskly and sometimes painfully upon the bowels, and producing copious watery stools. The aqueous extract purges moderately, without much griping, and is said to increase the flow of urine. The portion not taken up by water gripes severely. The watery extract obtained from jalap, previously exhausted by rectified spirit, is said to have no cathartic effect, but to operate powerfully by urine. (*Duncan.*) The alcoholic extract, usually called resin of jalap, purges actively, and often produces severe griping. From these facts it would appear that the virtues of this cathartic do not depend exclusively upon any one principle. Experiments, however, by Mr. John C. Long, of Philadelphia, seem to show that the gummy extract, which he took in the quantity of a drachm without any effect, is inert; while the soft resin, or that soluble in ether, which was thought to have but feeble power, if any, acted powerfully as a hydragogue cathartic in the dose of three grains. (*A. J. P.*, 1861, p. 489.) Jalap was introduced into Europe in the latter part of the sixteenth or the beginning of the seventeenth century, and now ranks among the purgative medicines most extensively employed. It is applicable to most cases in which an active cathartic is required, and from its hydragogue powers is especially adapted to the treatment of dropsy. It is generally given in connection with other medicines, which assist or qualify its operation. In dropsical complaints it is usually combined with potassium bitartrate. With calomel it forms a cathartic compound which has long been highly popular, in the United States, in bilious fever and other complaints attended with congestion of the liver or portal circle. In overdoses it may produce dangerous hypercatharsis. It is said to purge when applied to a wound. Jalapin when taken internally is probably absorbed, but as yet its presence has never been detected in the urine, and it remains uncertain whether it is eliminated or destroyed. Müller (*Inaug. Diss.*, Dorpat, 1885) found traces of it in the blood, and even in the heart, lungs, and spleen, of cats poisoned with it.

The dose of jalap in powder is from ten to twenty grains (0·65–1.3 Gm.); of the extract, from four to eight grains (0·26–0·52 Gm.); of the resin, from two to four grains (0·13–0·26 Gm.). The dose of calomel and jalap is five grains (0·33 Gm.) of each; of potassium bitartrate and jalap, two drachms (7·8 Gm.) of the former and from ten to fifteen grains (0·65–0·97 Gm.) of the latter.

"The bark of the root of Juglans cinerea, Linné (nat. ord. Juglandaceæ), collected in autumn." *U. S.*

Ecorce de Noyer gris, *Fr.;* Graue Wallnussrinde, *G.*

Gen. Ch. MALE. *Amentum* imbricated. *Calyx* a scale. *Corolla* six-parted. *Filaments* four to eighteen. FEMALE. *Calyx* four-cleft, superior. *Corolla* four-cleft. *Styles* two. *Drupe* coriaceous, with a furrowed nut. *Willd.*

Several products of *Juglans regia*, or common *European walnut*, are used medicinally in Europe. The hull of the fruit has been employed as a vermifuge from the times of Hippocrates, and has been recommended in syphilis and for old ulcers. The expressed oil of the fruit has been deemed efficacious against the tape-worm, and is also used as a laxative injection. The *leaves*, long occasionally employed for various purposes in both regular and domestic practice, have been found by Professor Négrier, of Angers, in the highest degree efficacious in scrofula. He gave to children a teacupful of a pretty strong infusion, or six grains of the aqueous extract, or an equivalent dose of a syrup prepared from the extract, two, three, or four times a day, and at the same time applied a strong decoction to the ulcers, and as a collyrium when the eyes were diseased. No injury ever resulted from a long-continued use of the remedy. It appears to act as a moderately aromatic bitter and astringent. (*Arch. Gén.*, 3e sér., x. 399 and xi. 41.) They are said also to have proved useful as a topical application in malignant pustule. (*Ibid.*, 5e sér.,

produced on grounds in Mexico belonging to them, is described by him in *A. J. P.* (Sept. 1868, p. 389), to which the reader is referred for a particular account of it. Though differing in shape and interior structure from genuine jalap, they had precisely the odor of that product, and a similar wrinkled appearance and mottled brown color externally, and were probably derived from a plant either of the same genus as jalap or of one closely related to it.

x. 609.)* The leaves of our *J. nigra*, or common *black walnut*,† and those of *J. cinerea*, probably possess the same properties.

Juglans cinerea. Willd. *Sp. Plant.* iv. 456; Bigelow, *Am. Med. Bot.* ii. 115; Carson, *Illust. of Med. Bot.* ii. 42, pl. 86; *B. & T.* 247.—*J. cathartica.* Michaux, *N. Am. Sylva*, i. 160. This is an indigenous forest tree, known in different sections of the country by the names of *butternut*, *oilnut*, and *white walnut*. In favorable situations it attains a great size, rising sometimes fifty feet, with a trunk three or four feet in diameter at the distance of five feet from the root. The stem divides, at a short distance from the ground, into numerous nearly horizontal branches, which spread widely and form a large tufted head. The young branches are smooth and of a grayish color, which has given origin to the specific name of the plant. The leaves are very long, and consist of from five to nine pairs of sessile leaflets, and a single petiolate leaflet at the end. These are two or three inches in length, oblong-lanceolate, rounded at the base, acuminate, finely serrate, and somewhat downy. The male and female flowers are distinct upon the same tree. The former are in large aments, four or five inches long, hanging down from the sides of the shoots of the preceding year's growth, near their extremity. The fertile flowers are at the end of the shoots of the season. The ovary is surmounted by two large, feathery, rose-colored stigmas. Sometimes a single fruit is suspended by a thin pliable peduncle; sometimes several fruits are attached to the sides and extremity of the same peduncle. The drupe is oblong-oval, with a terminal projection, hairy, viscid, green in the immature state, but brown when ripe. It contains a hard, dark, oblong, pointed nut, with a rough, deeply and irregularly furrowed surface. The kernel is thick, oily, and pleasant to the taste.

The butternut grows in Canada, and throughout the whole northern, eastern, and western sections of the old United States. In the Middle States, the flowers appear in May and the fruit ripens in September. The tree, if pierced immediately before the leaves unfold, yields a richly saccharine juice, from which sugar may be obtained, nearly if not quite equal to that from the sugar-maple. The wood, though neither strong nor compact, is useful for some purposes on account of its durability and its exemption from the attacks of worms. The fruit, when half grown, is sometimes made into pickles, and, when ripe, affords in its kernel a grateful article of food. The bark is used for dyeing wool a dark-brown color, though inferior for this purpose to that of the black walnut. It is said to be rubefacient when applied to the skin. The inner bark is the medicinal portion: that of the root, being considered most efficient, is directed by the Pharmacopœia. It should be collected in May or June.

On the living tree, the inner bark, when first uncovered, is of a pure white, which becomes immediately on exposure a fine lemon color, and ultimately changes to deep brown. It has a fibrous texture, and is officially described as follows: "In flat or curved pieces, about 5 Mm. thick; the outer surface dark gray and nearly smooth, or deprived of the soft cork and deep brown; the inner surface smooth and striate; transverse fracture short, delicately checkered, whitish and brown; odor feeble; taste bitter and somewhat acrid." *U. S.* Its medical virtues are extracted by boiling water. Dr. Bigelow could detect no resin in the bark; and the presence of tannin was not evinced by the test of gelatin, though a brownish-black color was produced by ferrous sulphate. Mr. Charles O. Thiebaud found the bark to be destitute of tannic acid and of any vegetable alkaloid, but to contain bitter extractive oily matter in large proportion, a volatilizable acid crystallizing in bright, orange-yellow crystals, and appearing to bear some analogy with chrysophanic acid, named *juglandic acid*, another acid crystallizing in tabular colorless crystals, and a volatile acid, with ashes, potassium largely, with traces of sodium, calcium, and aluminum. (*A. J. P.*, 1872, p. 253.) In a subsequent analysis, Mr. E. S. Dawson found resin in very small proportion, a volatile acid, and, in addition to the bases discovered by Mr. Thiebaud, magnesium, combined, as were the other bases, with carbonic, hydrochloric, phosphoric, and silicic acids. Prof. Maisch has no doubt that the juglandic acid of Mr. Thiebaud is the *nucin* of A. Vogel, Jr., found in green walnut peel. (*Ibid.*, April, 1874, 167.) E. D. Truman (*Ibid.*, 1893, 426) made proximate analyses of the root bark and the trunk

* *Nucitannic Acid.* In the walnut, between the kernel and the shell, is a thin membrane, which closely embraces the cotyledon, called the *episperm*, which consists of two layers, the inner very thin, colorless, translucent, and perfectly tasteless, the outer coarser, somewhat colored, and of a bitter, disagreeable taste. The latter, examined chemically by Dr. T. L. Phipson, was found to contain, among other principles, as gallic and ellagic acid, etc., a new variety of tannic acid, which he proposes to name *nucitannic acid* or *nucitannin*, to which the outer membrane chiefly owes its unpleasant taste. It is a glucoside; as when boiled for some hours with dilute hydrochloric acid it splits into glucose and a peculiar red acid substance, which he calls *rothic acid*, $C_{14}H_{12}O_7$, and the properties of which he has pretty thoroughly investigated. (*Chem. News*, Sept. 3, 1869, p. 116.)

† For an exhaustive chemical examination of black walnut leaves by Miss L. J. Martin, see *A. J. P.*, 1886, p. 468.

bark for comparison. In the trunk bark, instead of the crystallizable juglandic acid, he found an uncrystallizable acid and a crystalline resin. Tanret and Villiers isolated from the leaves a carbohydrate, *nucite*, $C_6H_{12}O_6 + 2H_2O$, which fuses at 218° C., is not fermentable, and does not reduce Fehling's solution. It has since been shown to be identical with *inosite*. Tanret also (*Jahresb. f. Pharm.*, 1876, 198) thinks that he has obtained an alkaloid from walnut leaves, which he proposes to call *juglandine*. The European walnut bark yielded *glycyrrhizin* abundantly to Sestini. *Juglon*, $C_{10}H_6O_3$, the characteristic constituent of *Juglans regia*, has been prepared synthetically by Bernthsen and Semper, and is now recognized as *α-oxynaphthoquinone*, $C_{10}H_5(OH)O_2$, as it can be made from dioxynaphthalene by the action of chromic acid mixture. It is in brownish-red crystalline needles having a faint odor of walnut hulls, and is sternutatory. (*Ber. der Chem. Ges.*, 1887, 934.)

Medical Properties and Uses. Butternut is a mild cathartic, operating without pain or irritation, and resembling rhubarb in the property of evacuating without debilitating the alimentary canal. It was much employed during our Revolutionary war by Dr. Rush and other physicians attached to the army. It is especially applicable to cases of habitual *costiveness* and other bowel affections, particularly *dysentery*, in which it has acquired considerable reputation. In connection with calomel it has sometimes been used in our *intermittent* and *remittent fevers*, and other complaints attended with congestion of the abdominal viscera. The official extract should always be preferred. The dose of it is from twenty to thirty grains (1·3–1·95 Gm.) as a purge, from five to ten grains (0·33–0·65 Gm.) as a laxative. Mr. E. S. Dawson states that a tincture, two troyounces of the bark in a pint of diluted alcohol, will act decidedly as a cathartic in the dose of from one to two fluidrachms (3·75–7·5 C.c.). (*A. J. P.*, 1874.)

KAMALA. U. S. Kamala.

(KA-MĀ'LA.)

"The glands and hairs from the capsules of Mallotus Philippinensis (Lamarck), Mueller Arg. (nat. ord. Euphorbiaceæ)." *U. S.*

Rottlera, *U. S.* 1870; Kameela, Spoonwood; Kalmie, *Fr.*, *G.*

The genus Rottlera was named in honor of the Rev. Dr. Rottler, a Danish missionary, and as now recognized was established by Roxburgh. It belongs to the natural order of Euphorbiaceæ, and includes another species having medical virtues, the *Rottlera schimperi*, a large tree of Abyssinia, the bark of which, under the name of *cortex musenæ*, or *musena bark*, has attracted some attention from its presumed anthelmintic virtues.*

Rottlera tinctoria (*Mallotus philippinensis*, De Cand. *Prodrom.* xv. 980; also (Lamarck) Mueller-Arg.), which is described and figured by Roxburgh in his treatise on *The Plants of the Coast of Coromandel* (ii. 36), is a small tree from fifteen to twenty feet in height, growing in Abyssinia and Southern Arabia, throughout Hindostan, in several of the East India islands, in China, and in Australia. The fruit is a roundish, three-valved, three-celled capsule, of about the size of a small cherry, marked externally with three furrows, and thickly covered with a red powder. This is the official part of the plant. Very large quantities of it are collected in Hindostan. The berries, placed in large baskets, are rolled about and rubbed with the hands, and the powder thus freed sifts through the open wicker-work.†

Properties. Kamala, as brought to our market, is a light, finely granular, very mobile powder, of a brownish-red or madder color, with little smell or taste, but producing a slight sense of acrimony in the mouth, and feeling gritty under the teeth. (When the grittiness is excessive, the drug has probably been adulterated with earthy matters.) It is inflammable, and flashes almost like gunpowder when dropped into the flame of a candle. It is insoluble in cold and but very slightly soluble in boiling water; but alkaline solutions, alcohol, and ether dissolve a large proportion of it, forming a deep red solution, from which water precipitates resinous

* *Cortex Musenæ.* This bark is in quills several inches long, an inch or more in diameter, rough and fissured externally, with a brown epidermis, and beneath this successively a thin greenish cellular coat, a thicker pale yellow periderm, and a tough, very fibrous liber. It is inodorous, but has a sweetish nauseous taste, followed by an enduring sense of acrimony in the fauces. It was found by Mr. C. Thiel to contain an acrid substance analogous to saponin, a bitter principle, a fatty wax-like substance, yellow coloring matter, extractive, and various salts. It is said to be used in Abyssinia, with kousso, in the treatment of tape-worm. (*Neues Jahrb. für Pharm.*, Jan. 1863.)

† A peculiar kind of kamala, evidently not the product of *Rottlera tinctoria*, has been imported from Aden. Under the microscope the grains are cylindrical or subconical, 170 to 200 mm. long by 70 to 100 broad, with oblong resin-cells arranged perpendicularly in three or four tiers. When heated to 212° F. the powder turns black. Under the name of *Vars*, *Wars*, or *Wurrus*, this drug is said to be used in Southern Arabia for the same purposes that kamala is employed for elsewhere. It is believed to be obtained from *Hemingia grahamiana*. (*P. J. Tr.*, Sept. 1887.)

matter, "imparting a deep red color to alkaline liquids, alcohol, ether, or chloroform, and a pale yellow tinge to boiling water." *U. S.* Under the microscope, it consists of garnet-red, semi-transparent, roundish, glandular granules, from $\frac{1}{500}$ to $\frac{1}{250}$ of an inch in diameter, and containing numerous red, club-shaped vesicles, more or less mixed with minute stellate hairs, and the remains of stalks and leaves, the latter of which are easily removed by careful sifting. It has been examined chemically by Dr. Thos. Anderson, of Glasgow, and by G. Leube, in Germany. As given by the former, the constituents are, in 100 parts, 78·19 of resinous coloring matter, 7·34 of albumen, 7·14 of cellulose, etc., a trace of volatile oil and volatile coloring matters, 3·84 of ashes, and 3·49 of water. The amount of earthy impurities, chiefly sand, in commercial kamala, varies greatly, sometimes amounting to fifty or even sixty per cent. It can readily be estimated by heating the drug to redness and weighing the residue. The U. S. Pharmacopœia allows of the presence of "not more than 8 per cent. of ash." Any specimen of kamala containing more than the official percentage of impurity should be rejected. Of the resinous coloring substances, Dr. Anderson obtained one in a pure state by allowing a concentrated ethereal solution to stand for two days, draining and pressing in bibulous paper the resulting mass of granular crystals, and purifying them from adhering resin by repeated solution in ether and recrystallization. To this substance he gave the name of *rottlerin*. It is in the form of minute crystalline plates, of a yellow color and a satin-like lustre, insoluble in water, sparingly soluble in cold but more so in boiling alcohol, and readily dissolved by ether, and by alkaline solutions, which assume a dark red color. Rottlerin melts when heated moderately, and at a higher heat is decomposed, giving off pungent vapors. Its formula, according to Dr. Anderson, is $C_{11}H_{10}O_3$. (*Chem. Centralbl.*, 1855, 372.) A. and W. Perkin (*Ber. d. Chem. Ges.*, 19, 3109) and Jawein (*Ibid.*, 20, 182) both state that rottlerin can be extracted from kamala by the action of carbon disulphide. Jawein gives its fusing point as 200° C., and says that it is easily soluble in hot alcohol and acetic acid. In a later communication of A. G. Perkin (*P. J. Tr.*, 1893, 159, 236), he states that when extracted with ether, kamala yields a dark brownish resinous product from which six distinct substances can be isolated. Five of these—viz., rottlerin, isorottlerin, a wax, and two resins, one of high and one of low melting point—form the principal constituents. There is also present a trace of a yellow crystalline coloring matter melting at from 192°–193° C. The formula $C_{11}H_{10}O_3$ for rottlerin is confirmed. Perkin also finds in kamala a small quantity of a sugar soluble in water; in a still later communication (*Journ. Chem. Soc.*, 1894, 230) he states that three colorless acids each containing nitrogen were produced by the action of nitric acid on rottlerin. Leube found a resin soluble in ether and cold alcohol, another resin soluble in ether and boiling alcohol, starch, gum extractive, tannin, albumen, and citric acid. He failed to obtain the rottlerin of Dr. Anderson. The ashes were in the extraordinary proportion of 25·85 per cent., and of the ashes 83·8 per cent. consisted of insoluble silica. Silica probably enters essentially into the constitution of the minute granules, and its presence accounts for their grittiness under the teeth. Leube failed to find rottlerin, but its existence has been abundantly confirmed by Mr. Thos. B. Groves, who states that it is changed by exposure, and may, therefore, be absent in old specimens. (*P. J. Tr.*, 1872, 228.) The active constituent is supposed to be the resin extracted by ether.

Medical Properties and Uses. Kamala is actively or even violently purgative in full doses, occasionally causing nausea, but seldom vomiting. It has been long used in India in the treatment of *tape-worm*, but its properties were first brought to general notice by Dr. C. Mackinnon, a British army surgeon in India. (*Indian Annals Med. Sci.*, 1854.) He found it extraordinarily efficient in the treatment of tænia, having used it in fifty cases and failed in bringing away the worm in two only. The testimony of other practitioners in India and Great Britain goes to confirm the statements of Dr. Mackinnon, and there can be little doubt of the vermifuge powers of the medicine. It is given, without previous preparation of the patient, in the dose of from one to three drachms (3·9–11·65 Gm.), suspended in water, mucilage, or syrup. In the latter dose it sometimes acts violently. The worm is usually expelled dead at the third or fourth stool. If the first dose fails to operate on the bowels, it may be repeated in four hours, or followed by a dose of castor oil. Dr. Anderson, a British army surgeon in India, has employed the medicine successfully in the form of tincture, made in the proportion of six ounces to sixteen fluidounces of rectified spirit, of which the dose is from one to four fluidrachms (3·75–15 C.c.). As an external remedy, kamala is used by the people of India in various affections of the skin, particularly *scabies*. Dr. Wm. Moore, of Dublin, has employed it usefully in *herpetic ringworm*. (*Dub. Hosp. Gaz.*, Nov. 15, 1857.)

KAOLINUM. Br. Kaolin.

(KĀ-Ǫ-LĪ'NŬM.)

"A native aluminium silicate, powdered, and freed from gritty particles by elutriation." *Br.*

Porcelain Clay, Fuller's Earth, Bolus Alba.

Kaolin, $Al_2(SiO_3)_3 + Al_2O(OH)_4$, occurs in abundant deposits as a decomposition product of felspar; the latter is a double silicate of aluminum and alkali, and in its weathering, the alkali is gradually eliminated. A pure kaolin contains approximately 47 per cent. of silica, 40 per cent. of alumina, and 13 per cent. of water.

Large deposits of kaolin have been recently opened in Florida. It is now used extensively for clarifying oils, such as lard and cotton-seed oils and mineral lubricating oils. The British Pharmacopœia describes it as "A soft whitish powder insoluble in *water* or in diluted acids. The product of its fusion with alkalies, digested in *water*, and neutralized with *hydrochloric acid*, affords the reactions characteristic of aluminium, a gelatinous precipitate of silica being formed."

Kaolin is used as an absorbent powder when dusted upon the surface of the body in irritated conditions of the skin. *Cimolite* is a perfumed powder having similar physical properties to kaolin. Kaolin is not easily affected by most chemical reagents, and it forms a good diluent or excipient for silver nitrate, potassium permanganate, or other salts which are decomposed by organic substances.

KINO. U. S., Br. Kino.

(KĪ'NŌ.)

"The inspissated juice of Pterocarpus Marsupium, Roxburgh (nat. ord. Leguminosæ)." *U. S.* "The juice obtained from incisions made in the trunk of Pterocarpus Marsupium, Roxb., evaporated to dryness." *Br.*

Gummi (s. Resina) Kino; Kino, *Fr., G., It.;* Quino, *Sp.*

The term kino was originally applied to a vegetable extract or inspissated juice taken to London from the western coast of Africa, and introduced to the notice of the profession by Dr. Fothergill. Vegetable products obtained from various other parts of the world, resembling kino in appearance and properties, afterwards received the same name; and much confusion and uncertainty existed, and in some degree still exist, in relation to the botanical and commercial history of the drug. We shall first give an account of the general properties of the medicines denominated kino, and then treat of the several varieties.

General Properties. Kino, as found in commerce, is usually in small, irregular, angular, shining fragments, seldom as large as a pea, of a dark reddish-brown or blackish color, very brittle, easily pulverizable, and affording a reddish powder, much lighter colored than the drug in its aggregate state. If in large masses, it may be reduced without difficulty into these minute fragments. It is without odor, and has a bitter, highly astringent taste, with a somewhat sweetish after-taste. It burns with little flame, and does not soften with heat. It imparts its virtues and a deep red color to water and alcohol, but is nearly insoluble in ether. Cold water forms with it a clear infusion. Boiling water dissolves it more largely; and the saturated decoction becomes turbid on cooling, and deposits a reddish sediment. The tincture is not disturbed by water. When long kept, it often gelatinizes, and loses its astringency. (See *Tinctura Kino.*) Kino undoubtedly consists chiefly of a modification of tannic acid or tannin, which has received the name of *kino-tannic acid*, with extractive, gum, and sometimes probably a little resin; but we need a careful analysis of the different well-ascertained varieties. The aqueous solution is precipitated by gelatin, the soluble salts of iron, silver, lead, and antimony, mercuric chloride, and sulphuric, nitric, and hydrochloric acids. The precipitate with iron is of an olive or greenish-black color. The alkalies favor the solubility of kino in water, but essentially change its nature and destroy its astringency. The Br. Ph. requires that kino should be almost entirely soluble in *alcohol* (90 per cent.), but should yield little or nothing to *ether*, and that not less than 80 per cent. should be soluble in boiling *water*.

1. East India Kino. Malabar Kino. This is the variety at present probably most used and most highly esteemed, and the only one recognized by the British and United States Pharmacopœias. Its origin was long unknown. It is now ascertained, through the researches of Drs. Pereira, Royle, Wight, and others, to be the product of *Pterocarpus marsupium*, a lofty tree growing upon the mountains of the Malabar coast of Hindostan. Kino is the juice of the tree extracted through longitudinal incisions in the bark and afterwards dried in the sun. Upon drying it breaks into small fragments, and is put into wooden boxes for exportation. It

is collected near Tellicherry, and exported from Bombay. It is sometimes imported into this country directly from the East Indies, but more commonly from London. From a communication in the *Journal of the Asiatic Society of Bengal*, by the Rev. F. Mason, it appears that kino is also collected in the Tenasserim provinces, in Farther India, and has been exported from Maulmain to Europe. It is produced by a tree called *Pa-douck*, which was supposed to be a species of Pterocarpus, although its precise characters were not certainly known. (*A. J. P.*, xxi. 134.) Dr. Christison subsequently recognized, in a description of this tree furnished to him by Mr. Begbie, of Maulmain, the precise characters of *Pterocarpus marsupium;* so that this kino has the same origin as that from Malabar. *Pterocarpus indicus*, of the Mauritius Islands, where it is known as *sang dragon*, also yields a red kino to commerce.

East India kino is in small, angular, glistening fragments, of a uniform consistence, appearing as if formed by the breaking down of larger masses. The larger fragments are opaque and nearly black; but minute splinters are sometimes translucent, and of a deep garnet redness when viewed by transmitted light. This variety of kino is very brittle, readily breaking between the fingers, and easily pulverized, affording a dark reddish powder, a portion of which, resulting from the mutual attrition of the fragments, is often found interspersed among them. When chewed, it softens in the mouth, adheres somewhat to the teeth, and tinges the saliva of a blood-red color. In odor, taste, and chemical relations it corresponds with the account already given of kino in general. When kino is boiled in water, the decoction deposits, on cooling, a bright red substance; and a similar deposition takes place when a cold filtered aqueous solution is long exposed with a broad surface to the air. According to Hennig, kino consists of tannic acid with a trace of gallic acid, kinoic acid, pectin, ulmic acid, and inorganic salts, with excess of earthy bases. (See *A. J. P.*, xv. 544.) C. Etti obtained a new constituent, *kinoin*, by extracting kino with ether. He finally adopted the following method as more practicable. One part of gum kino is added to 2 parts of boiling diluted (1–5) hydrochloric acid. Kino-red immediately separates as a soft mass, becoming gradually solid on cooling, while the *kinoin*, mixed with a small quantity of kino-red, remains in solution. The solid residue is once more boiled with water, the liquids are united and shaken with ether. The ethereal solution, on evaporation, leaves a crystalline reddish residue, which is dissolved in hot water, on the cooling of which tolerably pure crystals of *kinoin* are obtained. By continued recrystallization they are obtained colorless. Their formula is $C_{14}H_{12}O_6$, and *kino-red* is the anhydride of this: $2C_{14}H_{12}O_6 - H_2O = C_{28}H_{22}O_{11}$. This kino-red, heated to 160°–170° C., parts with a molecule of water and yields a lower anhydride, $C_{28}H_{20}O_{10}$. Both anhydrides are precipitated by gelatin, but kinoin itself is not. When heated with hydrochloric acid to 120°–130° C., kinoin yields methyl chloride, gallic acid, and catechol, and hence probably has the constitution of a *guaiacol* or *methyl-catechol gallate*. Kino contains about 1·5 per cent. of kinoin. (*Ber. d. Deutsch. Chem. Ges.; N. R.*, Feb, 1879.) Kremel found Malabar kino, Butea gum, eucalyptus kino, and the kino from *Coccoloba uvifera* to be free from Etti's kinoin, but to contain a body acquiring, like kinoin, a red color with ferric chloride, which proved to be *pyrocatechuic acid;* this was present either alone or mixed with gallic acid. (*A. J. P.*, 1883, 267.) For a description of the seeds of *Butea frondosa*, from which *Bengal kino* is produced, see *Pharm. Rev.*, 1896, 232.

2. West India, or Jamaica Kino. This is believed to be the product of the *Coccoloba uvifera*, or *sea-side grape*, a tree twenty feet or more in height, bearing beautiful broad shining leaves, and large bunches of purple berries, to which it owes its vernacular name. It grows in the West Indies and neighboring parts of the continent. The kino is said to be obtained by evaporating a decoction of the wood and bark, which are very astringent. Many years since, a thick reddish-brown liquid was imported into Philadelphia from the West Indies, which, when dried by exposure to the air in shallow vessels or by heat, afforded an extract having all the properties of kino, for which it was sold by the druggists. This has long been exhausted; but some years since, a considerable quantity of West India kino was brought into this market, which may still enter into the consumption of the country. It was contained in large gourds, into which it was evidently poured while in a liquid or semi-liquid state, and then allowed to harden. When taken from the gourd it breaks into fragments of various sizes, upon an average about as large as a hazelnut, and having some tendency to the rectangular form. The consistence of these fragments is uniform, their surface smooth and shining, and their color a dark reddish brown approaching to black. They are, however, neither so glistening nor so black as the East India kino. In mass they are quite opaque, but in thin splinters are translucent and of a ruby redness. They are readily broken by the fingers into smaller fragments,

are easily pulverized, and yield a dull-reddish powder, considerably lighter colored than that of the former variety. The West India kino is without color, and has a very astringent, bitterish taste, with a scarcely observable sweetish after-taste. It adheres to the teeth when chewed, though rather less than the East India variety, and colors the saliva red. The solubility of Jamaica kino was very carefully examined by Prof. Robert Bridges, who found that cold water dissolved 89 per cent., and ordinary official alcohol 94 per cent. The portion dissolved by alcohol and not by water was probably of a resinous nature, as it appeared to be viscid, and very much impeded the filtration of the watery solution. Considering the nature of this substance, the form of kino in which it was found is probably, like that from the East Indies, an inspissated juice. Guibourt, who states that Jamaica kino is but slightly dissolved by cold water, must have operated on a different product.

3. South American Kino. Caraccas Kino. In 1839, when the 4th edition of this Dispensatory was published, an astringent extract was described which had recently been introduced into our market, derived from Caraccas, and known by that name to the druggists. Since that period it has come much more extensively into use. It is probably the same as that described by Guibourt, in the last edition of his *History of Drugs*, as the kino of *Colombia*. As imported, this variety of kino is in large masses, some weighing several pounds, covered with thin leaves, or exhibiting marks of leaves upon their unbroken surface, externally very dark, and internally of a deep reddish-brown or dark port-wine color. It is opaque in the mass, but translucent in thin splinters, very brittle, and of a fracture always shining, but in some masses wholly rough and irregular, in others rough only in the interior, while the outer portion, for an inch or two in depth, breaks with a rather smooth and uniform surface, like that of the West India kino. This outer portion is easily broken into fine angular fragments, while the interior crumbles quite irregularly. Some of the masses are very impure, containing pieces of bark, wood, leaves, etc.; others are more homogeneous, and almost free from impurities. The masses are broken up by means of a mill so as to resemble East India kino, from which, however, this variety differs in being more irregular, less sharply angular, more powdery, and less black. On comparing the finer and more angular portions of the masses with the West India kino, the late Dr. Geo. B. Wood could discover no difference between the two varieties either in color, lustre, taste, or other sensible property. The colors of the powders were also identical. South American kino was found by Dr. Bridges to yield 93·5 per cent. to cold water, and 93 per cent. to alcohol; so that, while it has almost the same solubility as Jamaica kino in alcohol, it is somewhat more soluble in cold water. The aqueous solution in this case was not embarrassed by the adhesive matter which impeded the filtration in the former variety; and the want of a minute proportion of resinous matter in the South American kino is the only apparent difference between the two drugs. It is not improbable that they are derived from the same plant; and there is no difficulty in supposing that this may be the *Coccoloba uvifera*, as that tree grows as well upon the continent as in the islands.

4. African Kino. The original kino employed by Dr. Fothergill was known to be the product of a tree growing in Senegal, and upon the banks of the Gambia, on the western coast of Africa; but the precise character of the tree was not ascertained until a specimen, sent home by Mungo Park during his last journey, enabled the English botanists to decide that it was the *Pterocarpus erinaceus* of Lamarck and Poiret.* The Edinburgh and Dublin Colleges accordingly referred kino in chief to this plant, but, in so doing, overlooked the fact that not one of the varieties now used is brought from Africa. The importation of African kino has long ceased.† In 1896, however, a consignment of African kino reached London. It was

* A particular account of *Pterocarpus erinaceus* and its concrete juice, with a figure, by Dr. W. F. Daniell, is contained in the *P. J. Tr.* for August, 1854 (vol. xiv. p. 55).

† *Butea gum*, which has sometimes been mistaken for African kino, is the concrete juice of the *Butea frondosa*, or *Dhak-tree* of Hindostan, and also to some extent of *B. superba*. The juice flows from natural fissures, and from wounds made in the bark of the tree, and quickly hardens. It is in small elongated tears, or irregular angular masses, less in size than a grain of barley, apparently black and opaque, but translucent and of a ruby-red color when examined in small fragments by transmitted light; in some specimens the tears are much paler than described, and of a very beautiful ruby tint. Many of the tears have small portions of bark adhering to them. They are very brittle, and readily pulverizable, yielding a reddish powder. They are very astringent to the taste, do not adhere to the teeth when chewed, and tinge the saliva red. The relations of this product to water, alcohol, and other chemical reagents are nearly the same as those of ordinary kino. When freed from impurities, consisting of from 15 to 25 per cent. of wood, bark, sand, etc., it contains, according to Mr. E. Solly, 73·26 per cent. of tannin, 5·05 of soluble extractive, and 21·67 of gum and other soluble substances. It is used in the arts in India, and might undoubtedly be employed as kino in medicine. It is, however, very seldom imported into England, and never, at present, into this country. Dr. Pereira found a quantity in an old drug-store in London, and sent a portion to Guibourt, from which that writer drew up his description of African kino. It is possible that the kino which formerly reached us, full of small pieces of wood, bark, etc., may have been the *Butea gum*.

examined by E. M. Holmes, who stated that it was evidently yielded by *P. erinaceus.* (*Chem. and Drug.*, 1896, 226.) It is said to be still used by the Portuguese of Angola, under the name of *Sangue de Drago.* As described by Fothergill, the African kino, for which he proposed the name of *gummi rubrum astringens Gambinense*, was in lumps of about the size of those of gum Senegal or dragon's blood, and so similar in appearance to the latter that a good judge might easily be deceived. These lumps were hard, brittle, opaque, and almost black; but minute fragments were reddish and transparent like garnet. The drug was inodorous, of a strongly astringent and sweetish taste, and soluble in water to the extent of about five or six parts out of seven, forming a deep red astringent infusion. There can be little doubt that this variety of kino is a concrete juice, which exudes either spontaneously or from wounds in the bark, and hardens in the air. (*Med. Obs. and Inq.*, i. 358.)

5. Australian Kino. Botany Bay Kino. This kino was formerly supposed to be yielded by *Eucalyptus resinifera*, but is now known to be produced by a very large number of species. It is occasionally obtained in dried masses in the crevices in trees, sometimes by incisions into the bark, but more usually is simply scraped off the outside of the tree. It has been stated that five hundred pounds of the kino are sometimes yielded in a single year by one tree; but this seems to be a great exaggeration. Occasionally the juice reaches England unevaporated.* Australian kino usually occurs in dark, reddish-brown masses or grains, which when sufficiently thin may be translucent and garnet-like. It is very apt to contain much foreign matter, especially the scrapings from the bark. Coming from so many sources, it varies considerably in its physical characteristics and its relations to solvents. Although the Australian kino is produced by so many trees and is much used in Australia, it does not seem to be an important article of commerce. For further information concerning it the reader is referred to an elaborate paper on it by J. H. Maiden, in *P. J. Tr.*, Oct. 1889;† also *A. J. P.*, 1897, 1. Eucalyptus kino contains catechin, pyrocatechin, and kinoin, and in some specimens a volatile oil, giving a slightly aromatic odor to the drug which is especially developed by hydrochloric acid. (See also *Eucalypti Gummi.*)

6. Myristica Kino. There has been produced in Southern India a kino consisting of smaller or larger angular pieces, of deep garnet color, in thin fragments, and having the general characteristics of Malabar kino; according to E. Schaer, it is a product of *Myristica malabarica*, of *M. fragrans*, and probably of other species of the genus. In all important respects these kinos are said to correspond with Malabar kino, but to be distinguishable by containing crystals of calcium tartrate. As yet this variety of kino does not seem to have commercial importance.

In a later paper J. H. Maiden (*A. J. P.*, 1895, 575) announces the discovery in Australian kino of two new organic substances to which he gives the names *eudesmin* and *aromadendrin.* The former of these when purified exists as a pure white mass with a lustre resembling spermaceti. It is soluble in hot water, but crystallizes out again on cooling. It is soluble in alcohol, ether, acetic ether, and chloroform, but not in benzene, petroleum spirit, or carbon disulphide. It is dissolved by sulphuric acid with a dark color changing to purple, by nitric acid with a beautiful yellow color. Its formula is given as $C_{26}H_{30}O_8$, and its melting point as 99° C. The second substance was also obtained crystallized from boiling water, and melted at 162° C. No analysis has been made of it.

It is said that catechu, broken into small fragments, has sometimes been sold as kino. Fortunately, little injury can result from the substitution, as the medical virtues of the two substances are very nearly the same.

Medical Properties and Uses. Kino is powerfully astringent, and in this country is much used for the suppression of morbid discharges. In *diarrhœa*, not attended with febrile excitement or inflammation, it is often an excellent adjunct to opium and the absorbent medicines, and is a favorite addition to the chalk mixture. It is also used in *chronic dysentery* when astringents are admissible; in *leucorrhœa* and *diabetes;* and in *passive hemorrhages*, particularly

* *Kino juice* has a fine deep red color, a slightly aromatic odor, and a decidedly astringent taste, and on evaporation yields a genuine kino in varying amount. It must not be confounded with the so-called *Liquid Kino*, or *apple-tree juice*, which is obtained from incisions in the *Angophora intermedia* or *narrow-leaved apple-tree* of Australia. This varies from the consistency and colorlessness of water to an orange-brown or reddish-brown liquid as thick as molasses. It contains catechin and tannic acid, and is said to be especially employed for the purposes of tanning nets.

† The descriptions given by authors of this kino vary, because the Australian kinos themselves vary so much. Gathered with different degrees of care, and from probably fifty species of trees, they, of course, must be of varying character.

those from the uterus and the intestines. The dose of the powder is from ten to thirty grains (0·65–1·95 Gm.). The infusion may be made by pouring eight fluidounces of boiling water on two drachms of the extract, and straining when cool. Aromatics may be added, if deemed advisable. The dose is a fluidounce (30 C.c.). The proportion of alcohol in the tincture renders it frequently an unsuitable preparation. Locally applied, kino is often productive of benefit. Its infusion is useful as an injection in *leucorrhœa* and *obstinate gonorrhœa*, and thrown up the nostrils we have found it very efficacious in suppressing *epistaxis*. The powder is also a very useful application to indolent and flabby ulcers.

KRAMERIA. U. S. (Br.) Krameria. [Rhatany.]

(KRĂ-MĒ'RĬ-Ă.)

"The root of Krameria triandra, Ruiz et Pavon, and of Krameria Ixina, Linné (nat. ord. Polygaleæ)." *U. S.* "The dried root of (1) Para Rhatany, a species of Krameria, attributed to Krameria argentea, Mart.; or of (2) Peruvian Rhatany, Krameria triandra, Ruiz and Pavon." *Br.*

Krameriæ Radix, *Br.*, Rhatany Root; Radix Ratanhæ, *P. G.;* Radix Ratanhiæ; Ratanhia, *Fr.;* Ratanhiawurzel, *G.;* Ratania, *It., Sp.*

There is some dissension among botanists as to which natural order Krameria belongs. Chodat recently (*Arch. d. Sc. Phys. et Nat.*, t. xxiv., Nov. 1890) placed the genus in a distinct order by itself,—viz., the Krameriaceæ. Engler and Prantl consider its proper place to be among the Cæsalpinoideæ-Krameriеæ in the nat. ord. Leguminosæ.

Krameria triandra. Ruiz and Pavon, *Flor. Peruv.* i. 61. The rhatany plant is a shrub, having a long, much-branched, spreading root, of a blackish-red color; with a round, procumbent, very dark colored stem, divided into numerous branches, of which the younger are leafy and thickly covered with soft hairs, giving them a white, silky appearance. The leaves are few, sessile, oblong-ovate, pointed, entire, presenting on both surfaces the same silky whiteness with the young branches. The flowers are lake-colored, and stand singly on short peduncles at the axils of the upper leaves. There are only three stamens. The nectary consists of four leaflets, of which the two upper are spatulate, the lower roundish and much shorter. The fruit is globular, of the size of a pea, surrounded by stiff reddish-brown prickles, and furnished with one or two seeds. It is a native of the Peruvian Andes, growing in dry argillaceous and sandy places. It flowers at all seasons, but is at the height of its bloom in October and November. The root is dug up after the rains, and, according to Tschudi, it is especially obtained in the southern provinces of Peru. Closely allied to it is *K. Ixina* L., which is, however, distinguished by having four stamens, and occurs in Guinea and Northern Brazil. The name *rhatany* is said to express in the language of the Peruvian Indians the creeping character of the plant which yields the root.*

* There are various rhatanies in European commerce. *Savanilla*, or *New Granada Rhatany*, is yielded by the *K. tomentosa*, St. Hil. (*K. ixina*, var. β), growing in Colombia, British Guiana, and Northern Brazil. According to Flückiger and Hanbury, it is never so knotty and irregular as the true rhatany, and is well distinguished by its dull purplish-brown color, its thick, smooth bark (⅓ to ¼ the diameter of the wood), marked with longitudinal furrows and here and there deep transverse cracks, and by the bark not easily splitting off. Its tannic acid is different from that of the Peruvian drug. If the powdered root be shaken with water and reduced iron, filtered, and the liquid diluted with distilled water, an intense violaceous color will be produced. *Peruvian Rhatany*, similarly treated, gives a dingy brown. Thin sections of true rhatany, moistened with a ferrous salt, become grayish; Savanilla rhatany, violet. *Para Rhatany* was described by Berg in 1865, and is believed to be the root of *K. argentea*. It is in long pieces (some 16 to 20 inches), from an eighth to three-quarters of an inch in thickness, of a dark-gray or brownish color, and, like the Savanilla, becoming bluish black when immersed in a solution of ferrous sulphate, owing to the presence of tannic acid in the bark. In this variety the root has a peculiar elasticity distinguishing it from the Peruvian and Savanilla varieties. Some of the pieces exhibit numerous corky warts. There are also microscopical characters which distinguish it. Two forms of rhatany which M. Cotton has described as *Black and Brown Antilles Rhatany*, because produced in these islands, though admitted also to be derived from different places on the neighboring continent, have been pronounced by Dr. Flückiger, after a careful examination, to be identical with the Para rhatany. (*Pharm. Journ.*, July, 1870, p. 84.) According to the studies of R. G. Dunwoody, this rhatany contains the same active principles as the root of *K. triandra*, but in slightly less quantity. (*A. J. P.*, 1890.)

A rhatany appeared not long since in the London market from Guayaquil. It is described as a large woody root from one-half inch to two inches in diameter. The bark is of a reddish-brown color with blackish streaks, is thin in comparison to the meditullium, is of a fibrous texture, and is somewhat striated on the surface and dotted over with small warts. It has a very astringent taste, but no marked odor. Mr. E. M. Holmes thinks that it is not the product of the genus Krameria. According to the analysis of Mr. Passmore, *Guayaquil rhatany* contains a larger quantity of tannin than the Peruvian drug, but less than the Para or the Savanilla rhatany. (*P. J. Tr.*, xvi. 878.)

According to an analysis made in the University of Wisconsin, the *Krameria lanceolata*, Torrey, of North America yields 34·5 per cent. of extract and 17 per cent. of tannin, and is therefore richer than the official drug. When treated with iron it strikes a deep-purple color, and is thus easily distinguished from Para rhatany, which gives a dirty brown, and from Savanilla rhatany, which gives a violet color.

We receive rhatany in pieces of various shapes and dimensions, some being simple, some more or less branched, the largest as much as an inch in thickness, derived from the main body of the root, the smallest not thicker than a small quill, consisting of the minute ramifications. The pieces are often nearly cylindrical, and as much as two or three feet in length. Sometimes many of the radicles are united in a common head, which is short, and from half an inch to two inches or more in diameter. The roots are composed of a dark, reddish-brown, slightly fibrous, easily separable bark, and a central woody portion, less colored, but still reddish or reddish yellow: "From 1 to 3 Cm. thick, knotty and several-headed above, branched below, the branches long; bark smooth or, in the thinner pieces, scaly, deep rust-brown, 1 to 2 Mm. thick, very astringent, inodorous; wood pale brownish-red, tough, with fine medullary rays, nearly tasteless. The root of *Krameria Ixina* (Savanilla Rhatany) is less knotty and more slender and has a dark purplish-brown bark, about 3 Mm. thick." *U. S.* The British Pharmacopœia now recognizes two varieties of rhatany, which it describes as follows: "1. Para Rhatany occurs in cylindrical pieces, and is characterized by its purplish-brown color and smooth thick bark, marked at intervals by deep transverse cracks, and adhering firmly to the wood, which is of a pale reddish-brown color. Fracture short. 2. Peruvian Rhatany is characterized by its dark reddish-brown color and its yellowish woody axis, from which the bark readily separates. The bark is thinner than that of Para Rhatany, bright reddish brown internally, and rough and scaly except in the smaller pieces. Fracture splintery." Rhatany is without smell, but has a bitter, very astringent, slightly sweetish taste, which is connected with its medical virtues, and is much stronger in the cortical than in the ligneous part. The smallest pieces are therefore preferable, as they contain the largest proportion of the bark. The powder is of a reddish color. The virtues of the root are extracted by water and alcohol, to which it imparts a deep reddish-brown color. From the researches of Vogel, Gmelin, Peschier, and Trommsdorff, it appears to contain tannic acid, lignin, and minute quantities of gum, starch, saccharine matter, and an acid which Peschier considered as peculiar and named *krameric acid.* The tannic acid is in three states: 1st, that of purity, in which it is without color; 2d, that of phlobaphene or anhydride, in which it has lost its astringency and been rendered insoluble by the action of the air; and, 3d, that of extractive, which is a soluble combination of tannin and its anhydride, and is the substance which imparts to the infusion and tincture their characteristic reddish-brown color. (Soubeiran, *Journ. de Pharm.*, xix. 596.) The tannic acid of rhatany (*krameria-tannic* or *rhatania-tannic acid*) is separated by treating the ethereal extract of the bark with alcohol, and evaporating the alcoholic solution. It gives a dark-green precipitate with ferric chloride, a flesh-colored one with gelatin, and none with tartar emetic. (*Gmelin.*) The tannin of rhatany, in the presence of melted potassa, is transformed into *protocatechuic acid* and *phloroglucin*, and with dilute acids gives glucose and a peculiar red coloring principle, called *ratanhia red*, $C_{26}H_{22}O_{11}$. (*Journ. de Pharm. et de Chim.*, Janv. 1868, p. 73.) The proportion of red astringent matter obtained by Vogel was 40 per cent. The mineral acids and most of the metallic salts throw down precipitates with the infusion, decoction, and tincture of rhatany, and are incompatible in prescription.

In examining a specimen of extract of rhatany from America, Wittstein discovered an alkaloid, which he thought to be identical with tyrosine. A somewhat different result was obtained by M. Ruge, who, after an examination, showed that the new alkaloid is not identical with tyrosine, for it has the formula $C_{10}H_{13}NO_3$, whilst that of tyrosine is $C_9H_{11}NO_3$, but is rather homologous with it. Like tyrosine, it is an amido-acid, and forms salts equally with mineral acids and with strong bases. It was called *ratanhine* by Ruge. Gintl (*A. J. P.*, 1869, p. 300) obtained ratanhine from *resina d'angelim pedra*, a resin from Brazil. Dr. Kreitmair has also obtained this principle from a sample of extract of rhatany. (See *A. J. P.*, 1875, p. 266.)

Cold water, by means of displacement or percolation, extracts all the astringency of rhatany, forming a clear deep-red infusion, which upon careful evaporation yields an almost perfectly soluble extract. The root yields its virtues also to boiling water by maceration; but the resulting infusion becomes turbid upon cooling, in consequence of the deposition of apotheme taken up by the water when heated. By boiling with water a still larger proportion of the apotheme is dissolved, and a considerable quantity of the pure tannin becomes insoluble in cold water, and medicinally inert, either by combining with the starch which is also dissolved, or by conversion into apotheme through the agency of the atmosphere. The decoction is, therefore, an ineligible preparation, and the extract resulting from its evaporation, though greater in weight than that from the cold infusion, contains much less soluble and active matter. Alcohol dissolves a larger proportion of the root than water; but this success is owing to

the solution of apotheme, and the alcoholic extract contains little if any more of the astringent principle than that prepared by cold water, while it is encumbered with much inert matter. (See *Extractum Krameriæ.*)

Medical Properties and Uses. Rhatany is generally tonic and powerfully astringent, and may be advantageously given in *chronic diarrhœa*, *passive hemorrhages*, especially *menorrhagia*, some forms of *leucorrhœa*, and in all those cases in which kino and catechu are beneficial. It has long been used in Peru as a remedy in bowel complaints, as a corroborant in cases of enfeebled stomach, and as a local application to spongy gums. Ruiz, one of the authors of the Peruvian Flora, first made it known in Europe. It was not till after the year 1816 that it began to come into general use. It has the advantage over the astringent extracts imported, that, being brought in the state of the root, it is free from adulteration, and may be prescribed with confidence. The dose of the powder is from twenty to thirty grains (1·3–1·95 Gm.); but the decoction (an ounce to the pint) is preferable; the dose being from one to two fluidounces (30–60 C.c.). The extract, tincture, and syrup are official, and may be given in the dose, the first of from fifteen to twenty grains (0·97–1·3 Gm.), the second of from two to three fluidrachms (7·4–11·09 C.c.), and the third of half a fluidounce (14·8 C.c.). In the form of infusion, tincture, and extract, rhatany has been used locally in fissure of the anus, prolapsus ani, and leucorrhœa.

LACTUCARIUM. U. S. Lactucarium.

(LĂC-TŪ-CĀ′RI-ŬM.)

"The concrete milk-juice of Lactuca virosa, Linné (nat. ord. Compositæ)." *U. S.*

Lactucarium, *Fr.;* **Giftlattichsaft,** *G.*

The plants of this genus yield when wounded a milky juice, to which, indeed, they owe their generic name. In some of them this juice possesses valuable narcotic properties. This is the case, among others, with *L. sativa*, *L. virosa*, and *L. altissima*. It was supposed that our native *L. elongata*, or *wild lettuce*, might have similar virtues; and Dr. Bigelow was informed by physicians who had employed it that it acts as an anodyne, and promotes the secretion from the skin and kidneys. But, according to M. Aubergier, the milky juice of this plant is of a flat and sweetish taste without bitterness, contains much mannite, but no bitter principle, and is destitute of narcotic properties. (*Ann. de Thérap.*, 1843, p. 18.) The probability is that it is nearly or quite inert.* Therefore, though formerly holding a place in our national Pharmacopœia, it has been discarded. In Europe *Lactuca scariola* is said to be substituted for the official plant.

Lactuca sativa. Willd. *Sp. Plant.* ii. 1523; *B. & T.* 161. The garden lettuce is an annual plant. The stem, which rises above two feet, is erect, round, simple below, and branching in its upper part. The lower leaves are obovate, rounded at the end, and undulating; the upper are smaller, sessile, cordate, and toothed; both are shining, and of a yellowish-green color. The flowers are pale yellow, small, and disposed in an irregular terminal corymb. Before the flower-stem begins to shoot, the plant contains a bland pellucid juice, has little taste or smell, and is much used as a salad for the table; but during the period of inflorescence it abounds in a milky juice, which readily escapes from incisions in the stem, and has been found to possess decided medicinal as well as sensible properties. The juice is more abundant in the wild than in the cultivated plants. The original native country of the garden lettuce is unknown. The plant has been cultivated from time immemorial, and flourishes equally in hot and temperate latitudes. Some botanists suppose that *L. virosa* of the old continent is the parent of all the varieties of the cultivated plant.

Lactuca virosa. Willd. *Sp. Plant.* iii. 1526; Woodv. *Med. Bot.* p. 75, t. 31; *B. & T.* 160. The *acrid* or *strong-scented lettuce* is biennial, with a stem from two to four feet high, erect, prickly near the base, above smooth and divided into branches. The lower leaves are large, oblong-ovate, undivided, toothed, commonly prickly on the under side of the midrib, sessile, and horizontal; the upper are smaller, clasping, and often lobed; the bracts are cordate and pointed. The flowers are numerous, of a sulphur-yellow color, and disposed in a panicle. The plant is a native of Europe.

L. virosa is lactescent, and has a strong disagreeable smell like that of opium, and a bitter-

* An investigation of our native *Lactuca elongata* by Prof. Maisch has led to conclusions differing essentially from those of M. Aubergier. The milky juice collected by Prof. Maisch himself from plants in his neighborhood was converted quickly into a gelatinous mass, that shrunk much in drying, and, so far from a flat taste, had a persistent bitterness, and a heavy, nauseous, narcotic odor. Having prepared a syrup from this concrete juice, he gave it for trial to Drs. Da Costa and August Müller, who found it decidedly useful, and by the latter physician it was pronounced quite equal to the imported German lactucarium. (*A. J. P.*, 1869, p. 145.)

ish, acrid taste. It was admitted by the late Edinburgh and Dublin Pharmacopœias as one of the sources of lactucarium, which it is said to yield in greater quantity and of better quality than the garden lettuce. Mr. Schutz, of Germany, obtained only 17 grains, on the average, from a single plant of the garden lettuce, while a plant of *L. virosa* yielded 56 grains.

Lactucarium is chiefly produced in Scotland, in Rhenish Prussia, and in France. According to Mr. Fairgrieve, in Scotland * the plant cultivated is *L. virosa*, var. *montana*. Late in July or early in August the collectors proceed over the field, cutting the head of each stalk and scraping the flow into their vessels. This is repeated several times daily until the plants are exhausted. (*P. J. Tr.*, iii. 972.) M. Aubergier is said to have been the only French producer. He cultivated the *L. altissima*, a gigantic Caucasian plant, which reaches the height of 9 feet. In collecting, transverse incisions were made daily, beginning at the top. In Germany the plan is the same as that practised in Scotland.†

Lactucarium,‡ as brought from England, is in small, irregular lumps, about the size of a pea or larger, of a reddish-brown color externally, and of a narcotic odor and bitter taste. As prepared near Edinburgh, it is commonly in roundish, compact, and rather hard masses, weighing several ounces. (*Christison.*) A variety known in our market as *German lactucarium* is in pieces about an inch and a half long by an inch in thickness, four-sided, with one side convex and the three others flat, or slightly concave from shrinking, as if quarter sections of a saucer-shaped cake which had been divided before it was quite dry. The color on the outer or convex surface is darkish brown, that of the cut surfaces light yellowish brown. From experiments by Messrs. Parrish and Bakes, the German appears to be inferior to the English, as 44 per cent. of spirituous extract was obtained from the latter, and only 36 per cent. from the former, while the two extracts were about equal in their sensible properties. (*A. J. P.*, 1860, p. 226.) French lactucarium resembles the German, except in being in circular cakes about an inch and a half in diameter. The official description is as follows: "In sections of plano-convex, circular cakes, or in irregular, angular pieces, externally grayish-brown or dull reddish-brown, internally whitish or yellowish, of a waxy lustre; odor heavy, somewhat narcotic; taste bitter. It is partly soluble in alcohol and in ether. When triturated with water, it yields a turbid mixture, and, when boiled with water, it softens and yields a brownish-colored liquid which, after cooling, is not colored blue by iodine test-solution." *U. S.* In color, taste, and smell lactucarium bears considerable resemblance to opium, and has sometimes been called *lettuce opium*. It does not attract moisture from the air. It yields nearly half its weight to water, with which it forms a deep-brown infusion. It is partly soluble in ether and alcohol. From its resemblance in sensible properties and therapeutical effects to opium, it was conjectured to contain morphine, or some analogous principle; but this conjecture has not yet been verified. Buchner, Aubergier, and Walz claim severally to have discovered the active principle, which has been named *lactucin;* but the substances obtained by these different chemists are not exactly identical in properties; and the lactucin of Walz and Aubergier is considered by M. Lenoir as owing its bitterness to impurities, separated from which it is without taste and inert. For a full account of the earlier analyses of lactucarium, see 16th edition U. S. D. The later results are given below.§

* For the mode of cultivating and preparing lactucarium in England, see a communication by Mr. Thos. Fairgrieve to *P. J. Tr.*, June, 1873, p. 972.

† For various plans which have been suggested of collecting the drug, see 14th ed. U. S. D.

‡ The *thridace* of Dr. François, at one time supposed to be identical with lactucarium, is in all probability nothing more than the inspissated expressed juice of lettuce, and, indeed, was directed as such in the French Codex of 1837; the leaves being rejected, and the stalks alone, near the flowering period, being subjected to pressure.

§ Ludwig found, in 100 parts, 48·63 of substances insoluble in water, and 51·37 of substances soluble in water. Of the insoluble matter 42·64 parts were of *lactucerin* or *lactucone*, which he obtained by first exhausting lactucarium with water, then treating the insoluble residue several times with hot alcohol of 0·833, allowing the alcoholic solution to evaporate slowly, washing the yellowish substance thus procured with water, and purifying it by re-solution in alcohol, and crystallization. Thus obtained, it is in snow-white aggregated granules, dissolves in strong hot alcohol which deposits it on cooling, is readily soluble in ether but insoluble in water, becomes transparent and tenacious when moderately heated in a platinum dish, melts completely at a higher heat, with the escape of white odorous vapors, is incapable of saponification by caustic potassa, and is therefore not properly a fat, and in alcoholic solution faintly reddens litmus-paper. Besides this principle there were 3·99 parts of wax, and 2·00 of lignin and of a substance which swelled in ammonia, and was insoluble in water, alcohol, and ether. Of the 51·37 parts soluble in water, 6·98 were albumen, 1·75 lactucerin, held in solution by other substances, 27·68 bitter extract soluble in water and in alcohol, and 14·96 aqueous extract insoluble in alcohol of 0·830. The former of these extracts was found to contain a peculiar acid substance called *lactucic acid*, and the lactucin of Aubergier. *Lactucic acid* is of difficult crystallization, light yellow, strongly bitter, without sour taste, of an acid reaction, and readily soluble in alcohol and water. It has as much claim as any other discovered substance to be considered the active principle of lactucarium. *Lactucin*, purified by animal charcoal, is in white pearly scales, the solution of which exhibits no reaction with lead subacetate or solution of iodine. It is dissolved without change of color by concentrated sulphuric acid.

The ancients believed lettuce to be possessed of soporific properties, and many years ago Dr. J. R. Coxe, of Philadelphia, first proposed the employment of the inspissated milky juice as a medicine. It was chiefly, however, through the recommendation by Dr. Duncan, Sr., of Edinburgh, that the medicine came into use and was adopted as official in various pharmacopœias. It is claimed for it that it has, although in a very much inferior degree, the anodyne and calming properties of opium, without its disposition to derange the digestive organs. It has been employed in this country to some extent to allay *cough* and quiet *nervous irritation*, but we believe that the general experience is in accord with our own in finding it to be almost devoid of narcotic properties. We have never been able to obtain any good from its use. The dose is usually set down as from ten to twenty grains (0·65–1·3 Gm.), but much larger quantities may be given without obvious effects. Water distilled from lettuce (*eau de laitue*) is used in France as a mild sedative, in the quantity of from two to four ounces. The fresh leaves boiled in water are sometimes employed in the shape of cataplasm. It is said that in Egypt a mild oil is derived from the seeds, fit for culinary use.

LAMELLÆ. Discs.

Under this head are included in the British Pharmacopœia minute *gelatin discs* which contain traces of alkaloids, and which are designed to be inserted by oculists under the eyelid, in order to produce, through solution in the tears, such effects as they desire. A hot solution of gelatin containing the alkaloid in proper proportion is poured on a slightly greased glass or porcelain plate, cooled and dried, and then cut into discs, which, by previous calculation, will be found to contain the requisite quantity of medicament. A little glycerin is added to keep them from getting too hard and dry.

LAMELLÆ ATROPINÆ. Br. Discs of Atropine.

(LĄ-MĔL'LÆ ĂT-RŌ-PĪ'NÆ.)

"Discs of Gelatin, with some Glycerin, each weighing about $\frac{1}{50}$ grain (1·3 milligrammes), and containing $\frac{1}{5000}$ grain (0·013 milligramme) of Atropine Sulphate." *Br.*

LAMELLÆ COCAINÆ. Br. Discs of Cocaine.

(LĄ-MĔL'LÆ CŌ-CĄ-Ī'NÆ.)

"Discs of Gelatin, with some Glycerin, each weighing about $\frac{1}{50}$ grain (2.17 milligrammes), and containing $\frac{1}{50}$ grain (1·3 milligrammes) of Cocaine Hydrochloride.

"Each Disc is four times the strength of a Disc of Cocaine of the British Pharmacopœia of 1885." *Br.*

LAMELLÆ HOMATROPINÆ. Br. Discs of Homatropine.

(LĄ-MĔL'LÆ HŌ-MĂT-RŌ-PĪ'NÆ.)

"Discs of Gelatin, with some Glycerin, each weighing about $\frac{1}{50}$ grain (1·3 milligrammes), and containing $\frac{1}{100}$ grain (0·65 milligramme) of Homatropine Hydrobromide." *Br.*

LAMELLÆ PHYSOSTIGMINÆ. Br. Discs of Physostigmine.

(LĄ-MĔL'LÆ PHĬ-SŌ-STĬG-MĪ'NÆ.)

"Discs of Gelatin, with some Glycerin, each weighing about $\frac{1}{50}$ grain (1·3 milligrammes), and containing $\frac{1}{10000}$ grain (0·065 milligramme) of Physostigmine Sulphate." *Br.*

Besides the above ingredients, Ludwig found in lactucarium a substance resembling mannite, oxalic acid, another organic acid not well determined, a soft resin, potassa, magnesia, and ferric oxide. Distilled with diluted sulphuric acid, it gave an acid product smelling like lactucarium, which, saturated with calcium carbonate, and again distilled with potassium bisulphate, yielded an acid fluid having the odor of valerian. (*A. J. P.*, xx. 57.)

Kromayer (*Ann. Chem. Pharm.*, 105, p. 3) found also *lactucopikrin*, $C_{44}H_{32}O_{21}$, a brown, amorphous, and very bitter substance of weak acid reaction. It is easily soluble in water and alcohol. Ludwig's lactucic acid Kromayer considers to be an oxidation product of lactucopikrin.

Hesse (*Handwörterbuch*, iv. p. 8) prepared *lactucerin*, and finds it to crystallize in white needles, fusing point 210° C., soluble in hot ligroin, in chloroform, and in benzol. On fusion with potash it yields acetic acid and *lactuceryl alcohol*, $C_{18}H_{30}O$, which forms white needles, fusing at 162° C., and is easily soluble in ether, chloroform, and hot alcohol. Hesse has since (*Ann. der Ch. und Phar.*, 234, p. 243) determined that lactucarium contains the acetates of α- and β-*lactucerol*, $C_{18}H_{30}O$. These compound ethers are saponified with alcoholic potash and water added, which precipitates α- and β-lactucerol. These are washed, dried in the air, and taken up with boiling alcohol. On cooling, α-lactucerol separates out first and can be purified by recrystallization, while the β-lactucerol is obtained from the mother-liquor. The acetate of α-lactucerol fuses at 210° C., while that of β-lactucerol fuses at 230° C. For an examination of *Russian lactucarium*, by L. Schiperovitch, see *Pharm. Zeitschr. f. Russl.*, or *Drug. Circ.*, 1886.

LAPPA. U. S. Lappa. [Burdock.]

(LĂP'PA.)

"The root of Arctium Lappa, Linné, and of some other species of Arctium (nat. ord. Compositæ)." *U. S.*

Radix Bardanæ, *P. G.;* Bardane, *Fr.;* Klettenwurzel, *G.*

Gen. Ch. Coarse and rank biennials, of the Old World, unarmed, except the hooked tips of the involucral bracts forming the bur; with large and roundish, mostly cordate leaves, the lower on stout petioles, and middle-sized heads of pink or purplish flowers, in summer. (*Asa Gray.*)

The stem of the burdock is succulent, pubescent, branching, and three or four feet in height, bearing very large, cordate, denticulate leaves, which are green on their upper surface, whitish and downy on the under, and stand on long footstalks. The flowers are purple, globose, and in terminal panicles. The calyx consists of imbricated scales, with hooked extremities, by which they adhere to cloth and the coats of animals. The achenes are oblong, somewhat compressed and three-angled, ribbed, truncate. Although a native of Europe, burdock is abundant in the United States, where it grows on the roadsides, among rubbish, and in cultivated grounds. There are three recognized species of Arctium in North America,—viz., *A. tomentosum* (Lam.), Schk. (Woolly or Cottony Burdock); *A. Lappa*, L. (Burdock, Clotbur or Great Bur); and *A. minus*, Schk. (Common Burdock).

The burdock has a simple, spindle-shaped root a foot or more in length, brown externally and white and spongy within, furnished with thread-like fibres, and having withered scales near the top. It is officially described as "about 30 Cm. or more long, and, in its thickest portion, from 1 to 2 Cm. thick; nearly simple, fusiform, fleshy, longitudinally wrinkled, crowned with a tuft of whitish, soft, hairy leaf-stalks; grayish-brown, internally paler; fracture somewhat horny; bark rather thick, the inner part and the wood radially striate, the parenchyma free from starch,—often with cavities lined with white remains of tissue; odor feeble and unpleasant; taste mucilaginous, sweetish, and somewhat bitter." *U. S.* For medicinal purposes the root should be gathered when about a year old.

Inulin has been found in it by Guibourt, and sugar by Fée, while F. E. Hendershott believes that it contains a glucoside, besides arabin and pectin and extractives. (*Proceedings of Mich. Pharm. Assoc.*, 1887.) Professor Trimble also obtained from the root a bitter, crystalline glucoside. (*Pharm. Era*, 1888, p. 133.) Thos. Donaldson (*A. J. P.*, 1890, p. 123) found 8·6 per cent. of yellow fixed oil and about 1 per cent. of white waxy matter. The inulin usually exists in parenchymatous cells in a different state, but if sections of the green root be dehydrated by soaking in 95 per cent. alcohol, the inulin will be found in spheroidal form.

An interesting account of burdock and its use as an edible vegetable in Japan, by Inazo Nitobe, may be found in *A. J. P.*, 1897, 416.

Medical Properties. Burdock root is considered to be a diuretic and diaphoretic alterative, especially useful in the *gouty*, *scorbutic*, and *syphilitic* and *scrofulous diatheses;* also in various chronic skin diseases, especially in *psoriasis*, *prurigo*, and *acne*. (*Med. and Surg. Rep.*, 1868.) To prove effectual, its administration must be long continued. A pint may be given daily of the decoction, made by boiling two ounces of the root in three pints of water to two pints. The fluid extract and syrup have also been prepared. The fresh leaves have been employed both externally and internally in cutaneous eruptions and ulcerations. The fruit has been largely substituted for the root, especially in the form of the tincture of burdock fruit.

LAUROCERASI FOLIA. Br. Cherry-Laurel Leaves.

(LÂU'RŌ-CĔR'Ą-SĪ FŌ'LĮ-Ą.)

"The fresh leaves of Prunus Laurocerasus, Linn." *Br.* (Nat. ord. Rosaceæ.)

Laurier-cerise, *Fr.;* Kirschlorbeer, *G.;* Lauro-ceraso, *It.*

Cerasus lauro-cerasus. De Cand. *Prodrom.* ii. 540.—*Prunus lauro-cerasus.* Willd. *Sp. Plant.* ii. 988; *B. & T.* 98. This is a small evergreen tree, rising 15 or 20 feet, with long spreading branches, which, as well as the trunk, are covered with a smooth, blackish bark. The leaves, standing alternately on short strong footstalks, are oval-oblong, from five to seven inches in length, acute, finely toothed, firm, coriaceous, smooth, beautifully green and shining, with oblique nerves, and yellowish glands at the base. The flowers are small, white, strongly odorous, and disposed in simple axillary racemes. The fruit is an oval drupe, very similar in shape and structure to a small black cherry. The cherry-laurel is a native of Asia Minor, but is culti-

vated in Europe, both for medical use and for the beauty of its shining evergreen foliage. Almost all parts of it have more or less of the odor of hydrocyanic acid.

In their recent and entire state cherry-laurel leaves have scarcely any smell; but, when bruised, they emit the characteristic odor of the plant in a high degree. Their taste is somewhat astringent and strongly bitter, with the flavor of the peach kernel. They are officially described as "Thick, coriaceous, on short strong petioles, oblong or somewhat obovate, from five to seven inches (twelve and a half to seventeen centimetres) in length, tapering towards each end, recurved at the apex, distantly but sharply serrate and slightly revolute at the margins, dark green, smooth, and shining above, much paler beneath, and with a prominent midrib, on either side of which, near the base, are one or two glandular depressions." *Br.* They yield a peculiar oil and hydrocyanic acid by distillation with water, which they strongly impregnate with their flavor. One pound, avoirdupois, of the fresh leaves yields 40·5 grains of the oil. (*Centralbl.*, 1855, 205.) The oil resembles that of bitter almonds, for which it is said to be sometimes sold in Europe, where it is employed to flavor liquors and various culinary preparations, but, as the glucoside of cherry-laurel leaves is decomposed more slowly than ordinary crystallized amygdalin, it is liable to hold hydrocyanic acid, and hence to be poisonous. The glucoside referred to has been termed *laurocerasin*, or "amorphous amygdalin." It is decomposed by emulsion into hydrogen cyanide, benzaldehyde, and sugar, but more slowly than ordinary amygdalin. Its optical activity also differs from that of ordinary amygdalin. (Jacobsen, *Die Glycoside*, 25.) That the oil exists already formed, to a certain extent, in the fresh leaves, is rendered probable by the fact, stated by Winckler, that they yield it in considerable quantity when distilled without water. (*Journ. de Pharm.*, xxv. 195.) The fresh leaves are used to flavor milk, cream, etc., and more safely than the oil; though they also are poisonous, when too largely employed.

Medical Properties and Uses. The leaves of the cherry-laurel possess properties similar to those of hydrocyanic acid; and the water distilled from them is much employed in various parts of Europe for the same purposes as that active medicine. But it is deteriorated by age, and therefore, as kept by pharmacists, must be of variable strength. Mr. J. Bröker, a Dutch pharmacologist, has satisfied himself, by numerous experiments, that the proportion of hydrocyanic acid in the leaves varies with the season, the age of the plant, the character of the soil and of the weather, and thinks that, in consequence of this variability, they are inferior for medical use to bitter almonds, which in this respect have a more uniform composition. He found the proportion of the acid in the leaves greatest in July, and least in February. (*B. and F. Med.-Chir. Rev.*, Oct. 1868, p. 517.) It is not, therefore, to be regretted that the want of the plant in this country has prevented the general introduction of so variable a remedy as the distilled water. (See *Aqua Laurocerasi.*)

LEPTANDRA. U. S. Leptandra. [Culver's Root.]

(LEP-TĂN'DRA.)

The rhizome and roots of Veronica Virginica, Linné (nat. ord. Scrophularineæ)." *U. S.*

Culver's Physic, Black Root; Racine de Leptandra, ou de Véronique de Virginie, *Fr.*; Leptandra-Wurzel, *G.*

Gen. Ch. Calyx five-parted, segments acuminate. *Corolla* tubular-campanulate, border four-lobed, a little ringent, unequal, the lower lamina narrower. *Stamens* and at length the *pistils* much exserted; filaments below, and tube of the corolla pubescent. *Capsule* ovate, acuminate, two-celled, many-seeded, opening at the summit. *Nuttall.*

Veronica virginica, Linn.; Gray, *Man. of Bot., etc.* p. 290.—*Leptandra virginica.* Nuttall, *Genera of N. Am. Plants*, i. 7; Rafinesque, *Med. Flora*, vol. ii. This plant, commonly called *Culver's root*, or *Culver's physic*, is an herbaceous perennial, with a simple, erect stem, three or four feet high, smooth or downy, furnished with leaves in whorls, and terminating in a long spike of white flowers. The leaves, of which there are from four to seven in each whorl, are lanceolate, pointed, and minutely serrate, and stand on short footstalks. A variety was seen by Pursh with purple flowers, which was described and figured as a distinct species by Rafinesque, under the name of *L. purpurea.* The plant flowers in July and August. It grows throughout the United States east of the Mississippi, affecting mountain meadows in the South and rich woods in the North, and is not unfrequently cultivated.

Properties. The root consists of a rhizome or root-stalk several inches in length, sometimes branched, with numerous long slender radicles. As found in commerce, the rhizome is usually broken into pieces an inch or more long, from two to four lines in thickness, either beset with the rootlets or very rough from their remains when broken, very hard and firm, and

of difficult fracture, dark brown externally, light-colored and ligneous within. The rootlets are round, smooth, slender, generally broken, but, when not so, six inches or more in length, and almost black, being much darker colored than the caudex. The official description is as follows: "Of horizontal growth, from 10 to 15 Cm. long, and about 5 Mm. thick, somewhat flattened, bent and branched, deep blackish-brown, with cup-shaped scars on the upper side, hard, of a woody fracture, with a thin, blackish bark, a hard, yellowish wood, and a large, purplish-brown, about six-rayed pith; roots thin, wrinkled, very fragile; inodorous; taste bitter and feebly acrid." *U. S.* The odor is feeble and not disagreeable, the taste bitterish, somewhat nauseous, and feebly acrid. Water and alcohol extract the virtues of the root. For a microscopical description of leptandra, by A. P. Breithaupt, see *A. J. P.*, 1897, 235. According to Prof. E. S. Wayne, of Cincinnati, it contains volatile oil, extractive, tannin, gum, resin, and a peculiar crystalline principle, to which the virtues of the medicine may be ascribed. To this principle the name of *leptandrin* properly belongs. Prof. F. F. Mayer confirmed the presence of the crystalline principle, and proved it to be a glucoside. Prof. Wayne obtained it by treating an infusion of the root with lead subacetate, filtering, precipitating the excess of lead by sodium carbonate, filtering to separate the lead carbonate, passing the filtered liquid through animal charcoal which absorbed all the active matter, washing the charcoal with water till the washings began to be bitter, then treating it with boiling alcohol, and allowing the alcoholic solution to evaporate spontaneously. By dissolving the powder thus obtained in water, treating this with ether, and allowing the ether to evaporate, needle-shaped crystals were obtained, which had the bitter taste of the root. The resinous matter obtained by making a tincture of the root and precipitating this with water has been improperly called leptandrin, and considered the active principle. The pure resin is probably inert; and the preparation referred to owes what activity it may possess to some of the true leptandrin associated with it. Leptandrin is soluble in water, alcohol, and ether. It has not been isolated for use. (*Proc. A. P. A.*, 1856, p. 34.) Subsequently Mr. Wayne obtained from the root a saccharine principle having the properties of *mannite*. (*A. J. P.*, 1859, p. 557.) G. Steinmann (*A. J. P.*, 1887, p. 229) obtained pale lemon-yellow crystals of a peculiar agreeable odor and a very bitter taste. They were not precipitated from solution by Mayer's reagent or by tannin, and did not yield glucose on being boiled with dilute sulphuric acid.

Medical Properties. The recent root is said to act violently as a cathartic, and sometimes as an emetic. In the dried state it is much milder, but less certain. The practitioners calling themselves Eclectics consider it an excellent cholagogue, and use both the impure resin, which they call leptandrin, and the root itself as a substitute for mercurials.* Dr. A. P. Dutcher, of Cleveland, Ohio, has not found it to act decidedly on the liver, but believes that it has a special influence on the muciparous follicles of the intestines, and acts very advantageously in cases of *duodenal indigestion* and *chronic constipation*. (*Med. and Surg. Rep.*, March 28, 1868.) Prof. Rutherford, in his experiments upon dogs, found leptandrin to act rather feebly upon the liver. The full cathartic dose of the powder is from twenty grains to a drachm (1·3–3·9 Gm.); that of the impure resin referred to, from two to four grains (0·13–0·26 Gm.). Dr. J. Adolphus says that in the dose of from one to two grains (0·065–0·13 Gm.) the powder acts like rhubarb. On the same authority, from five to ten drops (0·3–0·6 C.c.) of a strong tincture, given every two hours, produce a mild aperient effect. (*Ibid.*, Jan. 11, 1868, p. 23.)

LIMONES. Lemons.

(LĪ-MŌ′NĒŞ.)

The fruit of Citrus Limonum.

Limons, Citrons, *Fr.;* Limonen, Citronen, *G.;* Limoni, *It.;* Limones, *Sp.*

LIMONIS CORTEX. U. S., Br. Lemon Peel.

(LĪ-MŌ′NĬS CÔR′TĔX.)

"The rind of the recent fruit of Citrus Limonum, Risso (nat. ord. Rutaceæ)." *U. S.* "The fresh outer part of the pericarp of the fruit of Citrus medica, Linn., var. β Limonum, Hook. f." *Br.* (Nat. ord. Aurantiaceæ.)

Limonis Pericarpium; Cortex Fructus Citri, *P. G.;* Ecorce (Zeste) de Citron, de Limon, *Fr.;* Citronenschale, Limonenschale, *G.*

* Prof. J. U. Lloyd communicated a process for resin of leptandra (or leptandrin) to the American Pharmaceutical Association in 1880. (See *A. J. P.*, 1880, 491.)

LIMONIS SUCCUS. U. S. (Br.) Lemon Juice.

(LĪ-MŌ'NĬS SŬC'CŲS.)

"The freshly expressed juice of the ripe fruit of Citrus Limonum, Risso (nat. ord. Rutaceæ)." *U. S.* "The freshly expressed juice of the ripe fruit of Citrus medica, Linn., var. β Limonum, Hook. fil." *Br.*

Succus Limonis, *Br.*, Succus Citri; Lime Juice; Suc de Citron (de Limon), *Fr.*; Citronensaft, Limonensaft, *G.*

For some general remarks on the genus CITRUS, see *Aurantii Cortex.*

Citrus medica. Willd. *Sp. Plant.* iii. 1426; Woodv. *Med. Bot.* p. 582, t. 189. This tree closely resembles *Citrus aurantium*, before described. The leaves, however, are larger, slightly indented at the edges, and stand upon footstalks which are destitute of the winged appendages that characterize the other species. The flowers, moreover, have a purplish tinge on their outer surface, and the fruit is entirely different in appearance from the orange. There are several varieties of *Citrus medica*, which some botanists consider as distinct species, but which scarcely differ except in the character of their fruit. Those particularly deserving of notice are the citron, lemon, and lime. 1. In the *citron*, *C. medica* of Risso (*Bentley & Trimen*, p. 53), the fruit is very large, sometimes six inches in length, ovoidal, with a double rind, of which the outer layer is yellowish, thin, unequal, rugged, with innumerable vesicles filled with essential oil; the inner is white, very thick and spongy. It is divided in the interior into nine or ten cells, filled with oblong vesicles, which contain an acid juice precisely like that of the lemon, and used for the same purposes. The rind is applied to the preparation of conserves, to which it is adapted by its thickness. The fruit is called *cédrat* by the French. 2. The *lemon* (*C. medica*, var. *limon* of Linnæus, *Citrus limonum* of Risso) (*Bentley & Trimen*, p. 54) is smaller than the preceding, with a smoother and thinner rind, a pointed nipple-shaped summit, and a very juicy, acid pulp. In other respects it closely resembles the citron, to which, however, it is usually preferred in consequence of the greater abundance of its juice. 3. The *lime* is still smaller than the lemon, with a smoother and thinner rind, oval, rounded at the extremities, of a pale-yellow or greenish-yellow color, and abounding in a very acid juice, which renders it highly useful for the purposes to which the lemon is applied. It is the product of the variety *C. acris* of Miller.

The *Citrus medica*, like the orange-tree, is a native of Asia. It is now known to grow wild in Northern India, and was introduced into Europe from Persia or Media. It was first cultivated in Greece, afterwards in Italy, as early as the second century, and has now spread over the whole civilized world, being raised by artificial heat where the climate is too cold to admit of its exposure during winter to the open air.

We are supplied with lemons and limes chiefly from the West Indies and the Mediterranean. Though the former of these fruits only is directed by the United States Pharmacopœia, both kinds are employed indiscriminately for most medicinal purposes; and the lime affords a juice at least equal, in proportional quantity and acidity, to that obtained from the lemon.*

As lemons rapidly deteriorate on keeping, if exposed to the air, the suggestions of protecting them by dipping them in melted paraffin, or by using a varnish of shellac dissolved in alcohol, made by Mr. George Mee, of London, are not without value. Mr. Mee found that lemons thus covered with varnish continued sound for many months. (See *A. J. P.*, 1866, p. 474.)

Properties. The exterior rind of the lemon has a fragrant odor, and a warm, aromatic, bitter taste, somewhat similar to that of the orange, though less agreeable. It is usually found in narrow, thin bands, with very little of the spongy, white, inner layer adhering to it. "The spongy, inner layer usually present in the segments should be removed before the Lemon Peel is used." *U. S.* It contains a bitter principle, and yields, by expression or distillation, an essential oil, which is much used for its flavor. Both this and the rind itself are recognized in the Pharmacopœias. (See *Oleum Limonis.*) When the white, spongy portion of the rind is boiled in water, and the decoction evaporated, crystals are deposited of a substance called *hesperidin.* This is a glucoside, and has the formula $C_{22}H_{26}O_{12}$, and is decomposed by dilute acids into hesperetin, $C_{16}H_{14}O_6$, and glucose, $C_6H_{12}O_6$. It turns dingy black when gently warmed with alcoholic solution of ferric chloride. It is bitter, but, as it is found most largely in the spongy and comparatively tasteless part of the rind, it may be doubted whether it is entitled to be considered as the active bitter principle. (See *A. J. P.*, xxvi. 553.) Lemon peel yields its virtues to water, wine, and alcohol. E. G. Clayton (*The Analyst*, 19, 134) calls

* *Limeseed Oil.* The seed of the lime contains 58 per cent. of fixed oil, which is said to equal in flavor the best olive oil. Its tendency to resist rancidity is reputed to be very great. (*Brit. and Col. Drug.*, 1894, 411.)

attention to the distinction between lemon peel and orange peel when moistened by strong hydrochloric acid. Orange peel under these circumstances changes in color from a yellow to a rich dark green color, while lemon peel retains its hue or assumes a dingy yellowish-brown tint. The juice is the part for which the fruit is most esteemed. It is sharply acid, with a peculiar grateful flavor, and consists chiefly of citric acid (some 10 per cent.), gum and sugar (from 3 to 4 per cent.), and inorganic salts (2·28 per cent.). It sometimes has in it a little volatile oil, derived by pressure from the rind. The U. S. P. gives the following standard tests: "Specific gravity: not less than 10·30 at 15° C. (59° F.). It has an acid reaction upon litmus paper, due to the presence of about 7 per cent. of citric acid. On evaporating 100 Gm. of the juice to dryness, and igniting the residue, not more than 0·5 Gm. of ash should remain." "A slightly turbid yellowish liquid, with a sharply acid taste. Specific gravity 1·030 to 1·040. One fluid ounce contains 30 to 40 grains (or 100 cubic centimetres contain 7 to 9 grammes) of citric acid. When Lemon Juice is evaporated to dryness, and the residue is incinerated, it should yield not more than 3 per cent. of ash. 110 minims (or 100 cubic centimetres) of Lemon Juice are neutralized by about 11½ grains (or 11·4 grammes) of Potassium Bicarbonate, by about 9½ grains (or 9·5 grammes) of Sodium Bicarbonate, and by about 16½ grains (or 16·5 grammes) of Sodium Carbonate." *Br.* As lemons cannot always be obtained, the juice is often kept in a separate state; but, from its liability to spontaneous decomposition, it speedily becomes unfit for medical use, and, though various means have been resorted to for its preservation, it can never be made to retain for any length of time its original flavor unaltered. The best substitute for lemon juice is a solution of crystallized citric acid in water, in the proportion of about an ounce to the pint, with the addition of a little oil of lemon; but even this solution is nearly useless as an antiscorbutic. One of the most effectual methods of preserving the juice is to allow it to stand for a short time after expression, till a coagulable matter separates, then to filter, and introduce it into glass bottles, with a stratum of almond oil or other sweet oil upon its surface. It will keep still better if the bottles containing the filtered juice be suffered, before being closed, to stand for fifteen minutes in a vessel of boiling water. Another mode is to add one-tenth of alcohol and to filter. The juice may also be preserved by concentrating it either by evaporation with a gentle heat, or by exposure to a freezing temperature, which congeals the watery portion and leaves the juice much stronger than before. When used, it may be diluted to the former strength; but, though the acid properties are retained, the flavor of the juice is found to have been deteriorated. Lemon syrup is another form in which the juice is preserved.

The British Pharm. (1885) gave the sp. gr. of lemon juice at from 1·035 to 1·045, and the quantity of citric acid in a fluidounce of it from 30 to 40 grains. Mr. W. W. Stoddart found, in lemons from six different sources, an average of 42·53 grains in an ounce of the juice, and a mean sp. gr. of 1·044. By other authorities the proportions are given very differently. Thus, Mr. Watts gives 20·5 grains to the ounce, or 4·7 per cent. of the juice. The fact is that the quantity of acid varies very greatly. Mr. Stoddart found it to diminish rapidly with the advance of summer, with little change in the sp. gr. (*P. J. Tr.*, Oct. 1868.) H. H. Robins, after examining large consignments of lemons, states that the average yield taken from a year's receipts was 35·23 grains in a fluidounce. (*Chem. and Drug.*, 1896, 742.) A solution of tartaric acid in water, with the addition of a little sulphuric acid, and flavored with the oil of lemon, has been fraudulently substituted for lemon juice, particularly as an antiscorbutic on long voyages, for which purpose it is quite useless. An application of the test for tartaric and sulphuric acids will at once detect the fraud.

Medical Properties and Uses. The rind of the lemon is sometimes used to qualify the taste and increase the power of stomachic infusions and tinctures. The juice is refrigerant, and, properly diluted, forms a refreshing and agreeable beverage in *febrile* and *inflammatory affections*. It may be given with sweetened water in the shape of lemonade, or may be added to the mildly nutritive drinks, such as gum-water, barley-water, etc., usually administered in *fevers*. It is also much employed in the formation of those diaphoretic preparations known by the names of *neutral mixture* and *effervescing draught*. (See *Mistura Potassii Citratis*, 1880.) One of the most beneficial applications of lemon juice is to the prevention and cure of *scurvy*, for which it may be considered almost a specific. For this purpose, ships destined for long voyages should always be provided with a supply of the concentrated juice. In England every foreign-going ship is required by law to take such a supply of lemon juice that every seaman shall have a daily allowance of an ounce after having been ten days at sea. It has been employed with advantage in *acute rheumatism* in doses of from one to four fluidounces (30–120

C.c.) from four to six times a day. It has been used with benefit as a local application in *pruritus of the scrotum*, in *uterine hemorrhage* after delivery, in *sunburn*,* and as a gargle in *diphtheritic sore throat.*

LINIMENTA. Liniments.

(LĬN-Ĭ-MĔN'TĄ.)

Embrocations, *E., Fr.;* Linimente, Einreibungen, *G.*

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand. The former official preparations belonging to this class which have been omitted in the present edition of the U. S. Pharmacopœia are the *Liniments of Cantharides* and *Subacetate of Lead.*

LINIMENTUM ACONITI. Br. Liniment of Aconite.

(LĬN-Ĭ-MĔN'TŬM ĂC-Ǫ-NĪ'TĪ.)

Liniment d'Aconit, *Fr.;* Akonitliniment, *G.*

"Aconite Root, in No. 40 powder, 20 *ounces* (Imperial) or 500 grammes; Camphor, 1 *ounce* (Imp.) or 25 grammes; Alcohol (90 per cent.), *a sufficient quantity.* Mix the powdered Aconite Root with *twenty fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; set aside in a closed vessel for three days, agitating occasionally; transfer to a percolator; when the liquid ceases to pass, continue the percolation with more of the Alcohol, allowing the liquid to drop into a receiver containing the Camphor, until *thirty fluid ounces* (Imp. meas.) or seven hundred and fifty cubic centimetres of the liniment are produced." *Br.*

The British preparation is simply a very strong tincture of aconite root and camphor; that of the U. S. P. 1870 † is almost equivalent to a fluid extract of aconite. Either may be applied alone by means of a camel's-hair pencil, or in connection with two parts or more of soap liniment or chloroform liniment, by rubbing it on the part affected. Experiments made by Mr. W. Donovan with a tincture prepared by macerating the fresh root, sliced, in rectified spirit for only twenty-four hours, proved that the preparation thus made, though acting in the same way, was much more powerful than the official (*Br.*). (*P. J. Tr.*, 2d ser., vi. 57.) The inference is that the fresh root should be used in preparing this liniment, and that a simple maceration is all that is required. There is a great waste both of aconite and of spirit in the process, as no provision is made, either by displacement with water or by expression, to separate from the mass in the percolator the strongly impregnated spirit retained in it. According to Mr. J. T. Porter, it requires twenty-eight parts, by measure, for every sixteen parts, by weight, of the dry root. On expressing the marc the loss of spirit was reduced to from 6 to 12 per cent. (*Ibid.*, xi. 66.) It is to be regretted that percolation to exhaustion and partial evaporation were not directed, as in the U. S. process for fluid extracts.

LINIMENTUM AMMONIÆ. U. S., Br. Ammonia Liniment.

(LĬN-Ĭ-MĔN'TŬM ĄM-MŌ'NĮ-Æ.)

Liniment of Ammonia, Volatile Liniment; Linimentum Ammoniatum, *P. G.;* Linimentum volatile, Linimentum ammoniacale; Liniment ammoniacal (volatil), Savon ammoniacal, *Fr.;* Flüchtiges Liniment, Flüchtige Salbe, *G.*

"Ammonia Water, *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims]; Alcohol, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Cotton Seed Oil, *six hundred cubic centimeters* [or 20 fluidounces, 138 minims], To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them by agitation in a bottle, which should be well stoppered. This Liniment should be freshly prepared, when wanted." *U. S.*

"Solution of Ammonia, 1 *fl. ounce* (Imperial measure) or 25 cubic centimetres; Almond Oil, 1 *fl. ounce* (Imp. meas.) or 25 cubic centimetres; Olive Oil, 2 *fl. ounces* (Imp. meas.) or 50 cubic centimetres. Shake together." *Br.*

The process of the U. S. Pharmacopœia differs from that of the U. S. P. 1870 not only in the proportion of ammonia water, which has been slightly reduced, but in the substitution of cotton seed oil for olive oil. The addition of 5 per cent. of alcohol prevents immediate separation, renders the mixture more uniform, and aids materially in binding together the oily and

* An excellent formula for this purpose is: glycerin and lemon juice, each, a fluidounce, bismuth subnitrate one drachm; to be applied freely to the affected parts.

† *Linimentum Aconiti*, U. S. 1870. "Take of Aconite Root, in fine powder, *eight troyounces;* Glycerin *a fluidounce;* Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of Alcohol, and let it macerate for twenty-four hours; then pack it in a conical percolator, and gradually pour Alcohol upon it until two pints of tincture have been obtained. Distil off a pint and a half of alcohol, and evaporate the remainder until it measures seven fluidounces; to this add the Glycerin, and mix them thoroughly."

aqueous constituents. A liniment is now furnished which is liquid at ordinary temperatures. The ammonia liniment of the U. S. P. 1870 was usually solid and unmanageable. Whilst complete saponification is not a desideratum in this liniment, a better oil than cotton seed oil is lard oil, which will form a white, smooth mixture.

The U. S. and British Pharmacopœias agree at present very nearly in the strength of this liniment; the U. S. preparation being somewhat the stronger. In the process, the ammonia reacts with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white, opaque emulsion. The liniment is an excellent rubefacient, frequently employed in *inflammatory affections of the throat*, in *catarrhal and other pectoral complaints of children*, and in *rheumatic pains*. It is applied by rubbing it, or placing a piece of flannel saturated with it, over the affected part. Should it occasion too much inflammation, it must be diluted with oil.

LINIMENTUM BELLADONNÆ. U. S., Br. Belladonna Liniment.

(LĬN-Ĭ-MĔN'TUM BĔL-LĂ-DŎN'NÆ.)

Liniment of Belladonna; Liniment de Belladone, *Fr.;* Belladonna-Liniment, *G.*

"Camphor, *fifty grammes* [or 1 ounce av., 334 grains]; Fluid Extract of Belladonna Root, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Camphor in about *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the Fluid Extract, and then add enough of the latter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Liquid Extract of Belladonna, 10 *fl. ounces* (Imperial measure) or 250 cubic centimetres; Camphor, 1 *ounce* (Imp.) or 25 grammes; Distilled Water, 2 *fl. ounces* (Imp. meas.) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Dissolve the Camphor in *six fluid ounces* (Imp. meas.) or one hundred and fifty cubic centimetres of the Alcohol; add the Liquid Extract of Belladonna, the Distilled Water, and sufficient of the Alcohol to produce *twenty fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Liniment. Set aside for twenty-four hours; filter." *Br.* The process for the liniment of the British Pharmacopœia has been improved by using an assayed liquid extract. It affords a valuable means of applying belladonna externally.

LINIMENTUM CALCIS. U. S., Br. Lime Liniment. [Carron Oil.]

(LĬN-Ĭ-MĔN'TUM CĂL'CIS.)

Liniment of Lime; Liniment calcaire, Savon calcaire, *Fr.;* Kalkliniment, *G.*

"Solution of Lime, Linseed Oil, of each, *one volume*. Mix them by agitation." *U. S.* "Solution of Lime, 2 *fl. ounces* (Imperial measure) or 50 cubic centimetres; Olive Oil, 2 *fl. ounces* (Imp. meas.) or 50 cubic centimetres. Shake together." *Br.*

The lime forms a soap with the oil, of which there is a great excess, that separates upon standing. Olive oil, as directed by the British Pharmacopœia, is often substituted for that of flaxseed, which was originally used, but it possesses no other advantage than that of having a less unpleasant odor. The use of cotton seed oil in the U. S. P. 1880 did not meet the expectations of those who proposed it, and the U. S. P. 1890 has reinstated linseed oil. This is a very useful application in recent *burns* and *scalds*, when smeared thickly upon lint or cotton batting. It is sometimes called *Carron oil*, from having been much employed at the Carron iron-works in Scotland.

LINIMENTUM CAMPHORÆ. U. S., Br. Camphor Liniment.

(LĬN-Ĭ-MĔN'TUM CĂM'PHŌ-RÆ.)

Liniment of Camphor, Linimentum Camphoratum, Oleum Camphoratum; Camphorated Oil; Liniment camphré, Huile camphrée, *Fr.;* Kampferliniment, *G.*

"Camphor, in coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Cotton Seed Oil, *eight hundred grammes* [or 28 ounces av., 96 grains], To make *one thousand grammes* [or about two pints]. Introduce the Camphor and the Cotton Seed Oil into a suitable flask, and apply a gentle heat, by means of a water-bath, loosely stoppering the flask during the operation. Agitate from time to time, until the Camphor is dissolved." *U. S.*

"Camphor, in flowers, 1 *ounce* (Imperial) or 20 grammes; Olive Oil, 4 *fl. ounces* (Imp. meas.) or 80 cubic centimetres. Dissolve the Camphor in the Olive Oil." *Br.*

S. D. Wetterstroem prefers cold solution to the official method, thus avoiding any loss of camphor. (*West. Drug.*, 1897, 68.) This is employed as an anodyne embrocation in *sprains, bruises, rheumatic or gouty affections of the joints*, and other local pains. It is also supposed to

have a discutient effect when rubbed upon glandular swellings. J. Weichselbaum has found camphor liniment to be a specific for the itching produced by cowhage. (*A. J. P.*, xlii. 519.)

LINIMENTUM CAMPHORÆ AMMONIATUM. Br. Ammoniated Liniment of Camphor.

(LĬN-Ĭ-MĔN'TŬM CĂM'PHŌ-RÆ ĂM-MŌ-NĪ'Ā-TŬM.)

Compound Liniment of Camphor, *Br.;* Liniment camphré ammoniacal, *Fr.;* Ammoniak- und Kampfer-Liniment, *G.*

"Camphor, 2½ *ounces* (Imperial) or 50 grammes; Oil of Lavender, 1 *fl. drachm* (Imp. meas.) or 2·5 cubic centimetres; Strong Solution of Ammonia, 5 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity.* Dissolve the Camphor and Oil of Lavender in *twelve fluid ounces* (Imp. meas.) or two hundred and forty cubic centimetres of the Alcohol; add the Strong Solution of Ammonia gradually, shaking them together until, after adding sufficient of the Alcohol to produce *twenty fluid ounces* (Imp. meas.) or four hundred cubic centimetres of the Liniment, a clear solution is formed." *Br.*

This is used as a rubefacient and at the same time anodyne embrocation in local pains, particularly of a rheumatic character.

LINIMENTUM CHLOROFORMI. U. S., Br. Chloroform Liniment.

(LĬN-Ĭ-MĔN'TŬM ȼHLŌ-RŌ-FÖR'MĪ.)

Liniment of Chloroform; Liniment au Chloroforme, *Fr.;* Chloroform-Liniment, *G.*

"Chloroform, *three hundred cubic centimeters* [or 10 fluidounces, 69 minims]; Soap Liniment, *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims]. To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix them by agitation." *U. S.*

"Chloroform, 2 *fl. ounces* (Imperial measure) or 50 cubic centimetres; Liniment of Camphor, 2 *fl. ounces* (Imp. meas.) or 50 cubic centimetres. Mix." *Br.*

A very great improvement was made in this preparation by the Committee of Revision of 1880, in the substitution of soap liniment for the olive oil. This change had been proposed in a previous edition of this Dispensatory, and it was desirable on account of the greasy residue which was left on the skin by the old preparation. The British Pharmacopœia has retained the oily vehicle. This is an excellent local application in painful affections. As the chloroform rapidly evaporates, it is desirable, in order to obtain its full anodyne effect, to guard against this by using waxed paper, or some other impermeable covering.

LINIMENTUM CROTONIS. Br. Liniment of Croton Oil.

(LĬN-Ĭ-MĔN'TŬM CRŌ-TŌ'NĬS.)

Liniment crotonné, *Fr.;* Krotonöl-Liniment, *G.*

"Croton Oil, 1 *fl. ounce* (Imperial measure) or 20 cubic centimetres; Oil of Cajuput, 3½ *fl. ounces* (Imp. meas.) or 70 cubic centimetres; Alcohol (90 per cent.), 3½ *fl. ounces* (Imp. meas.) or 70 cubic centimetres. Mix." *Br.*

This is a pustulating preparation, the irritant influence of which has been increased by the substitution of the oil of cajuput and the spirit for the olive oil of the original formula. From ten to thirty minims (0·6–1·9 C.c.) or more may be rubbed upon a limited surface, and repeated twice a day or oftener till an eruption is produced.

LINIMENTUM HYDRARGYRI. Br. Liniment of Mercury.

(LĬN-Ĭ-MĔN'TŬM HĪ-DRÄR'ǤY-RĪ.)

Linimentum Mercuriale; Liniment mercuriel, *Fr.;* Quecksilber-Liniment, *G.*

"Ointment of Mercury, 1 ounce (Imperial) or 30 grammes; Strong Solution of Ammonia, 160 minims (Imp. meas.) or 10 cubic centimetres; Liniment of Camphor, *a sufficient quantity.* Add the Strong Solution of Ammonia to sufficient of the Liniment of Camphor to produce *one fluid ounce and a half* (Imp. meas.) or forty-five cubic centimetres; triturate the Ointment of Mercury with sufficient of the Liniment of Camphor to produce *one fluid ounce and a half* (Imp. meas.) or forty-five cubic centimetres; mix the two liquids." *Br.*

This is a stimulating liniment, employed for the discussion of chronic glandular enlargements, swellings of the joints, and venereal tumors, and to promote the absorption of fluid. It is said to be more apt to salivate than is mercurial ointment. One fluidrachm (3·7 C.c.) may be rubbed upon the affected part night and morning. It should be thoroughly agitated before being applied.

LINIMENTUM OPII. Br. Liniment of Opium.

(LĬN-Ị-MĔN'TŬM Ō'PĮ-Ī.)

Anodyne Liniment; Liniment opiacé, *Fr.*; Opiumliniment, *G.*

"Tincture of Opium, 2 *fl. ounces* (Imperial measure) or 50 cubic centimetres; Liniment of Soap, 2 *fl. ounces* (Imp. meas.) or 50 cubic centimetres. Mix; set aside for a few days; filter." *Br.*

This is commonly called *anodyne liniment*, and is employed as an anodyne and gently rubefacient embrocation in *sprains*, *bruises*, and *rheumatic* or *gouty pains*. We are informed that the preparation which has been commonly used under the name of *anodyne liniment* is that of the late London Pharmacopœia, as given in former editions of the U. S. Dispensatory, consisting of one part by measure of tincture of opium and three parts of soap liniment, and consequently having only half the opiate strength of the present British liniment.

LINIMENTUM POTASSII IODIDI CUM SAPONE. Br. Liniment of Potassium Iodide with Soap.

(LĬN-Ị-MĔN'TŬM PŌ-TĂS'SĮ-Ī Ī-ŎD'Ị-DĪ CŬM SĄ-PŌ'NĒ.)

Liniment savonneux ioduré, *Fr.*; Jodkalium-Seifenliniment, *G.*

"Curd Soap, recently prepared and in shavings, 2 *ounces* (Imperial) or 40 grammes; Potassium Iodide, 1½ *ounces* (Imp.) or 30 grammes; Glycerin, 1 *fl. ounce* (Imp. meas.) or 20 cubic centimetres; Oil of Lemon, 1 *fl. drachm* (Imp. meas.) or 2·5 cubic centimetres; Distilled Water, 10 *fl. ounces* (Imp. meas.) or 200 cubic centimetres. Reduce the Curd Soap to fine shreds; mix it with the Distilled Water and Glycerin in a porcelain dish on a water-bath; when the Soap is dissolved, pour the liquid into a mortar in which the Potassium Iodide has previously been powdered; mix briskly by trituration; continue the trituration until the mixture is cold; set aside for an hour; then rub well the Oil of Lemon into the cream-like product." *Br.*

This preparation is apparently intended, by application to the surface, which may be attended with a gentle friction, to produce the absorption of the iodide, and thus to obtain its alterative and deobstruent effects through the circulation. The soap and glycerin act as demulcents, and thus obviate in some measure the local irritation of the salt.*

LINIMENTUM SAPONIS. U. S., Br. Soap Liniment.

(LĬN-Ị-MĔN'TŬM SĄ-PŌ'NĬS.)

Tinctura Saponis Camphorata, *U. S.* 1850; Camphorated Tincture of Soap; Linimentum Saponato-Camphoratum Liquidum, *P. G.*; Liquid Opodeldoc; Liniment savonneux camphré, *Fr.*; Flüssiger Opodeldok, *G.*

"Soap, in fine powder, *seventy grammes* [or 2 ounces av., 205 grains]; Camphor, in small pieces, *forty-five grammes* [or 1 ounce av., 257 grains]; Oil of Rosemary, *ten cubic centimeters* [or 162 minims]; Alcohol, *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Introduce the Camphor and the Alcohol into a suitable bottle, and shake until the Camphor is dissolved. Then add the Soap and Oil of Rosemary, and shake the bottle well for a few minutes. Lastly, add enough Water to make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims], and again shake until the liquid becomes clear. Set it aside, in a cool place, for twenty-four hours, then filter." *U. S.*

"Soft Soap, 2 *ounces* (Imperial) or 40 grammes; Camphor, 1 *ounce* (Imp.) or 20 grammes; Oil of Rosemary, 3 *fl. drachms* (Imp. meas.) or 7·5 cubic centimetres; Alcohol (90 per cent.), 16 *fl. ounces* (Imp. meas.) or 320 cubic centimetres; Distilled Water, 4 *fl. ounces* (Imp. meas.) or 80 cubic centimetres. Dissolve the Soap in the Distilled Water; dissolve the Camphor and Oil of Rosemary in the Alcohol; mix the solutions; set aside for one week; filter." *Br.*

* It seems to have been clearly established by the discussion carried on in *P. J. Tr.*, 2d ser., xi., that Castile soap, and even individual brands of soap, vary so much that it is impossible to get uniform results from the former official process, the preparation sometimes being beautifully transparent and jelly-like, at other times opaque and ointment-like. Various remedies were proposed, but finally Mr. N. Smith called attention to the fact that the formula adopted by the reviewers of the Pharmacopœia differs from the original one of Dr. Rumsey. This Mr. Smith states to be as follows: "Take of White Curd Soap (made from Russian tallow) two ounces; Potassium Iodide one ounce and a half; Glycerin one ounce; Distilled Water ten ounces; Essential Oil of Lemon one drachm. Reduce the Soap into fine shreds, and melt in a water-bath, with the whole of the Water and the Glycerin; when the Soap is perfectly dissolved, pour it into a No. 9 Wedgwood mortar in which the potassium iodide has been previously reduced to fine powder; mix briskly, and continue the trituration until the mortar has become cool and the liniment assumes the character of ice-cream. Set aside for an hour, after which gently rub in the Oil of Lemon." It will be noticed that Dr. Rumsey's process has been practically adopted by the present British Pharmacopœia.

This process is intended to furnish a saturated solution of Castile soap. The recommendation in the 16th edition of this Dispensatory, that powdered soap be used in preference to soap in shavings in this liniment, has been adopted by the U. S. P. 1890, for powdered soap does not vary greatly in the proportion of water left in it; the process is one recommended by Prof. Geo. W. Sloan, of Indianapolis, and if all the details are carefully followed it is a great improvement over that of the U. S. P. 1880. The British preparation is now made with soft (potash) soap; this method was recommended by J. T. Hornblower. (*Chem. and Drug.*, 1894, 571.) The liniment is said to be made more quickly and precipitation is avoided. In 1859 Mr. Dean showed that sodium oleate is freely soluble in alcohol, while the palmitate is nearly insoluble, consequently the latter salt is left behind in the British process. Although olive oil contains a large percentage of olein, yet it has been proposed to substitute almond oil,* for it is still richer. The economy of this is, however, very doubtful. Castor oil has also been suggested. (*A. J. P.*, xliv. 529.) G. H. Barckhausen states that the potassa soaps are perfectly soluble in alcohol, and suggests rape-seed oil as a good base. (*A. J. P.*, 1873, p. 17.)

In former editions of the U. S. Pharmacopœia, this preparation, though commonly called *Soap Liniment*, received the name of *Tinctura Saponis Camphorata*, to distinguish it from a similar preparation called *Opodeldoc*, which, having a soft semi-solid consistence, held the title *Linimentum Saponis Camphoratum*.†

Soap Liniment is much used, as an anodyne and gently rubefacient embrocation, in *sprains, bruises*, and *rheumatic* or *gouty pains*.

LINIMENTUM SAPONIS MOLLIS. U. S. Liniment of Soft Soap.

[Tinctura Saponis Viridis, Pharm. 1880.]

(LĬN-Ī-MĔN'TUM SĀ-PŌ'NĬS MŎL'LĬS.)

"Soft Soap, *six hundred and fifty grammes* [or 22 ounces av., 406 grains]; Oil of Lavender Flowers, *twenty cubic centimeters* [or 325 minims]; Alcohol, *three hundred cubic centimeters* [or 10 fluidounces, 69 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Oil of Lavender Flowers with the Alcohol, dissolve in this the Soft Soap by stirring or agitation, and set the solution aside for twenty-four hours. Then filter it through paper, and pass enough Water through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

This is the *tincture of green soap* of Prof. Hebra under a new name: it should never have been called Tinctura Saponis Viridis, as it belongs clearly in the class of liniments and is always used externally. C. E. Smith suggested the preparation of this liniment from the fixed oil directly, which has the advantage of convenience as well as of greater uniformity of strength.‡

LINIMENTUM SINAPIS COMPOSITUM. U. S. (Br.) Compound Liniment of Mustard.

(LĬN-Ī-MĔN'TUM SĪ-NĀ'PĬS CŌM-PŎS'Ī-TŬM.)

Linimentum Sinapis, *Br.*, Liniment of Mustard; Liniment sinapisé composé, *Fr.*; Zusammengesetztes Senfliniment, *G.*

"Volatile Oil of Mustard, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Fluid Extract of Mezereum, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Camphor, *sixty*

* A formula for making almond oil soap on the small scale may be found in *P. J. Tr.*, 2d ser., xi. 417.

† *Opodeldoc.* "Take of Common Soap, sliced, *three ounces*; Camphor *an ounce*; Oil of Rosemary, Oil of Origanum, each, *a fluidrachm*; Alcohol *a pint*. Digest the Soap with the Alcohol, by means of a sand-bath, till dissolved; then add the Camphor and Oils, and, when they are dissolved, pour the liquid into broad-mouthed bottles. This liniment has, when cold, the consistence of a soft ointment." *U. S. P.* 1850.

This preparation differs from the official Linimentum Saponis chiefly in being prepared with common white soap, made with animal fat, instead of Castile soap, which is made of olive oil. The former is peculiarly adapted to the purposes of this formula, in consequence of assuming, when its alcoholic solution cools, the consistence characteristic of the liniment. It is customary after the solution of the soap has been effected to pour the liquid into small wide-mouthed glass bottles, containing about four fluidounces, in which it concretes into a soft, translucent, uniform, yellowish-white mass. This liniment melts with the heat of the body.

‡ *Liniment of Soft Soap.* Dissolve 75 Gm. potassa in 200 C.c. of water, put the solution in a bottle of about 1500 C.c. capacity, add 325 Gm. linseed oil and 300 C.c. alcohol, and shake the mixture briskly for some time, until there is no further separation of oil on standing. Let the solution stand in a moderately warm place for twenty-four (to forty-eight) hours, then dissolve in it 20 C.c. oil of lavender, add enough water to make the product measure 1000 C.c., mix and filter. The process is easily finished in ten days, the main precaution to be observed being that the potassa be neither stronger nor weaker than 90 per cent., unless allowance be made for difference in strength. Refined cotton-seed oil or olive oil may be used instead of linseed oil without changing the proportion of potassa, but these oils usually produce a liniment of lighter color than would be obtained from linseed oil. (*A. J. P.*, 1896, 187.)

grammes [or 2 ounces av., 51 grains]; Castor Oil, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Camphor in *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol, and add the Fluid Extract of Mezereum; then add the Oil of Mustard and the Castor Oil and, finally, enough Alcohol to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Volatile Oil of Mustard, 1½ *fl. drachms* (Imperial measure) or 2 cubic centimetres; Camphor, 120 grains (Imp.) or 3 grammes; Castor Oil, 5 *fl. drachms* (Imp. meas.) or 7 cubic centimetres; Alcohol (90 per cent.), 4 *fl. ounces* (Imp. meas.) or 43 cubic centimetres. Dissolve the Camphor in the Alcohol; add the Oil of Mustard and Castor Oil; mix." *Br.*

This preparation is slightly weaker than the British. It affords a convenient method of applying the volatile oil of mustard, and may often be appropriately used as a substitute for sinapisms. The extract of mezereon is also a very energetic irritant. The castor oil seems to be added in order to increase somewhat the consistence of the liniment, and was probably chosen from among oleaginous substances in consequence of its solubility in alcohol. The effect is increased if the liniment be applied on flannel, and volatilization guarded against by covering it with oiled silk. For the circumstances calling for the use of this liniment, see *Sinapis.*

LINIMENTUM TEREBINTHINÆ. U. S., Br. Turpentine Liniment.

(LĬN-Ī-MĔN'TUM TĔR-Ē-BĬN'THĪ-NÆ.)

Liniment of Turpentine; Liniment térébenthiné, *Fr.;* **Terpentinliniment,** *G.*

"Resin Cerate, *six hundred and fifty grammes* [or 22 ounces av., 406 grains]; Oil of Turpentine, *three hundred and fifty grammes* [or 12 ounces av., 151 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the Resin Cerate in a capsule, on a water-bath, then add the Oil of Turpentine, and mix them thoroughly." *U. S.*

"Soft Soap, 1½ *ounces* (Imperial) or 37·5 grammes; Distilled Water, 5 *fl. ounces* (Imp. meas.) or 125 cubic centimetres or a sufficient quantity; Camphor, 1 *ounce* (Imp.) or 25 grammes; Oil of Turpentine, 13 *fl. ounces* (Imp. meas.) or 325 cubic centimetres. Mix the Soft Soap with *two fluid ounces* (Imp. meas.) or fifty cubic centimetres of the Distilled Water; dissolve the Camphor in the Oil of Turpentine; gradually add the latter solution to the former, triturating until the mixture becomes a thick creamy emulsion; lastly mix with sufficient Distilled Water to produce *one pint* (Imp. meas.) or five hundred cubic centimetres." *Br.*

The U. S. preparation is the liniment originally proposed by Dr. Kentish, and subsequently so highly lauded as a remedy in *burns* and *scalds.* It should be applied as soon after the occurrence of the accident as possible, and should be discontinued when the peculiar inflammation excited by the fire is removed. The best mode of application is to cover the burnt or scalded surface with pledgets of patent lint saturated with the liniment. It should not be allowed to come in contact with the sound parts. This liniment may also be successfully applied in other cases of cutaneous inflammation requiring stimulation, as in certain conditions of *erysipelas.* The present British preparation, so far as regards its rubefacient operation, may be looked upon as almost undiluted oil of turpentine; the soft soap having little other effect than to give consistence to the liniment, and the camphor acting as an anodyne, and both being too small in bulk to dilute the oil materially. It is a very ineligible and variable preparation.

LINIMENTUM TEREBINTHINÆ ACETICUM. Br. Liniment of Turpentine and Acetic Acid.

(LĬN-Ī-MĔN'TUM TĔR-Ē-BĬN'THĪ-NÆ Ā-CĔT'Ī-CŬM.)

Liniment térébenthiné acétique, *Fr.;* **Terpentin- und Essig-Liniment,** *G.*

"Oil of Turpentine, 4 *fl. ounces* (Imperial measure) or 100 cubic centimetres; Glacial Acetic Acid, 1 *ounce* (Imp.) or 25 grammes; Liniment of Camphor, 4 *fl. ounces* (Imp. meas.) or 100 cubic centimetres. Mix." *Br.*

This is a powerful rubefacient liniment, combining the irritant properties of the oil of turpentine and acetic acid, though somewhat diluted by the camphor liniment.* Glacial acetic acid was substituted for acetic acid in the 1885 revision in equivalent proportion: the change is an improvement pharmaceutically, as it now affords a clear solution.

* *St. John Long's Liniment.* Under this name a liniment is often used which is made as follows: "Take the yolk of one egg, 5 fluidrachms of Acetic Acid, 3 fluidounces of Oil of Turpentine, 2½ fluidounces of Rose Water, and ½ fluidrachm of Oil of Lemon. Make an emulsion."

LINUM. U. S., Br. Linseed. [Flaxseed.]

(LĪ'NŬM.)

"The seed of Linum usitatissimum, Linné (nat. ord. Lineæ)." *U. S.* "The dried ripe seeds of Linum usitatissimum, Linn." *Br.*

Lini Semina, *Br.* (1885); Semen Lini, *P. G.;* Grains de Lin, Semence de Lin, *Fr.;* Leinsame, Flachssamen, *G.;* Semi di Lino, *It.;* Linaza, *Sp.*

LINUM CONTUSUM. Br. Crushed Linseed.

(LĪ'NŬM CŌN-TŪ'SŬM.)

"Linseed reduced to a coarse powder." *Br.*

Linum usitatissimum. Willd. *Sp. Plant.* i. 1533; *B. & T.* 39. Common flax is an annual plant, with an erect, slender, round stem, about two feet in height, branching at top, and, like all other parts of the plant, entirely smooth. The leaves are small, lanceolate, acute, entire, of a pale-green color, sessile, and scattered alternately over the stem and branches. The flowers are terminal, and of a delicate-blue color. The calyx is persistent, and composed of five ovate, sharp-pointed, three-nerved leaflets, which are membranous on their border. The petals are five, obovate, striated, minutely scalloped at their extremities, and spread into funnel-shaped blossoms. The filaments are also five, united at the base; and the germ, which is ovate, supports five slender styles, terminating in obtuse stigmas. The fruit is a globular capsule, about the size of a small pea, having the persistent calyx at the base, crowned with a sharp spine, and containing ten seeds in distinct cells. This highly valuable plant, now almost everywhere cultivated, is said by some to have been originally derived from Egypt, by others from the great elevated plain of Central Asia. It flowers in June and July, and ripens its seeds in August.*

The seeds are oval, oblong, flattened on both sides, with acute edges, somewhat pointed at one end, one to two lines in length, smooth, glossy, brown externally, and yellowish white within, "covered with a transparent, mucilaginous epithelium, which swells considerably in water; the embryo whitish or pale greenish, with two large, oily, plano-convex cotyledons, and a thin perisperm." *U. S.* They are inodorous, and have an oily mucilaginous taste. Meyer found in them fixed oil, wax, resin, extractive, tannin, gum, nitrogenous mucilage, starch, albumen, gluten, and various salts. M. Meurein could find no starch, but detected phosphates, which had escaped the notice of Meyer. (*Journ. de Pharm.*, 3e sér., xx. 97.) Their investing coat abounds in a peculiar gummy matter or mucilage, which is readily imparted to hot water, forming a thick viscid fluid, that lets fall white flakes upon the addition of alcohol, and affords a copious dense precipitate with lead subacetate. The viscid mucilage of linseed cannot be filtered until it has been boiled. It contains in the dry state more than 10 per cent. of mineral substances; when freed from these and dried at 110° C., it corresponds, like althæa-mucilage, to the formula $C_{12}H_{20}O_{10}$. The seeds by exhaustion with cold or warm water afford of it about 15 per cent. By boiling with nitric acid, it yields crystals of mucic acid; by dilute mineral acids, it is broken up into dextrogyre gum, sugar, and cellulose. (Kirchner and Tollens, *Ann. der Chem.*, 175, 215.) Jorissen and Hairs (*Drogues Simples*, Planchon et Collin, t. ii. 685) have obtained from the young plant a glucoside, to which they give the name of *linamarin*, which crystallizes in colorless needles without odor, but possessing a fresh and bitter taste. It differs from amygdalin in not being decomposed by emulsion, but dilute acids decompose it into sugar, hydrocyanic acid, and a third product which is volatile and possesses certain of the characters of the acetones. Linseed contains about 4 per cent. of nitrogen, corresponding to about 25 per cent. of protein substances. After expression of the oil these substances remain in the cake, so that the latter contains 5 per cent. of nitrogen and constitutes a very important article for feeding cattle. In the ripe state linseed is altogether destitute of starch, though this substance is found in the immature seed in the very cells which subsequently yield the mucilage. The mucilage may be considered, as in analogous cases, to be a product of the

* The linseeds in commerce have been divided by Mr. E. M. Holmes into two groups. The first group, characterized by the seeds being of sufficient size for six or seven to weigh a grain, contains Bombay, Bold Calcutta, Sicilian, and Ionian seed; in the group of small seeds (10 to 12 to the grain) are English, Dutch, Russian, and ordinary Calcutta varieties. An important practical point noticed by Mr. Holmes is that many of these seeds are apparently purposely adulterated with weed seeds, which are nearly always smaller than the linseeds, and can therefore be separated by the sieve. When linseed meal is to be made for medical use, this separation should always be insisted upon, as many of the weed seeds are from Cruciferæ, and are irritating. For detailed information as to varieties of linseed, weed seeds, etc., the reader is referred to Mr. Holmes's paper. (*P. J. Tr.*, July, 1881; also *N. R.*, 1881.)

transformation of starch. (Flückiger, *Pharmacographia*, 2d ed., p. 99.) The interior of the seed, or nucleus, is rich in a peculiar oil, which is separated by expression, and extensively employed in the arts. (See *Oleum Lini.*)

The ground seeds are found in commerce under the name of *flaxseed meal.* This is of a dark-gray color, highly oleaginous, and when mixed with hot water forms a soft adhesive mass, much employed for luting by practical chemists. "*Ground Linseed* (Linseed Meal, or Flaxseed Meal), for medicinal purposes, should be recently prepared, free from unpleasant or rancid odor. When extracted with carbon disulphide, it should yield not less than 25 [30 per cent., Br. Ph.] per cent. of fixed oil.* The filtered infusion of Ground Linseed, prepared with boiling water and allowed to cool, has an insipid, mucilaginous taste, and should not be colored blue by iodine test-solution (absence of *starch*)." *U. S.* The cake remaining after the expression of the oil, usually called *oil-cake*, or, when ground, *cake-meal*, retains the mucilaginous matter of the envelope, and affords a nutritious food for cattle. The average composition of linseed oil-cake is thus given by Schaedler (*Technologie der Fette und Oele*, 1883): moisture, 10·56 per cent.; oil, 9·83 per cent.; non-nitrogenous fibre, 44·61 per cent.; ash, 6·5 per cent.; proteid matter, 28·5 per cent. Much of the linseed meal of commerce is simply cake-meal, which was, indeed, official in the former Br. Ph.; but such meal is unfit for medicinal use, not only because it contains very little oil, but also because the oil which is in it has, through rupture of the cells and partial expression, been so exposed to the air as to produce rancidity. Linseed meal is sometimes adulterated with corn meal, or other meals containing starch, whose presence is at once revealed by the iodine test.

Medical Properties and Uses. Flaxseed is demulcent and emollient. The mucilage obtained by infusing the entire seeds in boiling water, in the proportion of half an ounce to the pint, is much and very advantageously employed in *catarrh*, *dysentery*, *nephritic* and *calculous complaints*, *strangury*, and other inflammatory affections of the mucous membranes of the lungs, intestines, and urinary passages. By decoction water extracts a portion of the oleaginous matter, which renders the mucilage less fit for administration by the mouth, but superior as a laxative enema. The meal mixed with hot water forms an excellent emollient poultice.

LIQUORES. Solutions.

(LĮ-QUŌ′RĒŞ—lę-kwō′rēz.)

Solutés, *Fr.*; Lösungen, *G.*

The U. S. Pharmacopœia includes in this class of preparations all *aqueous* solutions without sugar in which the substance acted on is wholly soluble in water, excluding those in which the dissolved matter is gaseous or very volatile, as in the Aquæ, or Waters.

Although several changes were made in the strength of preparations of this class in the U. S. Pharmacopœia of 1880 for the sake of round numbers and to adjust the relative quantity of solid to the solvent, so as to avoid fractions in the percentages, yet it was a question whether these were advantages sufficient to overbalance the *disadvantage* of changing the doses of important preparations. Since the important change was made then, which makes the powerful solution to contain one per cent. of active ingredient, it would certainly be a serious mistake to alter this proportion to any extent in the future.

In the British Pharmacopœia it has been deemed expedient, in almost all instances in which the substance to be dissolved is an isolated solid body, to make the solutions of uniform strength, without regard to the physiological powers of the medicine, or its ordinary dose. There is a convenience in this plan to the prescriber, in relation to all medicines which habitually present themselves to his mind in the solid state; but to alter the strength of a solution which has been long known, and the dose of which is familiar, in order to make it conform with others, is to run the risk of frequent serious errors for the sake of an idea. The Br. Pharm. 1898 introduced under this head ten concentrated infusions, with the object of affording an easy method of making, through dilution, ordinary infusions. Their titles (see *Liquor Calumbæ Concentratus*) are very inappropriate.

* The value of a sample of crushed linseed can be absolutely determined only by analysis. It should contain from 25 to 35 per cent. of oil, not more than 8 or 8·5 per cent. of husk, and less than 8 per cent. of ash. The following *test* is said to be sufficient for practical purposes: "Put half an ounce of the meal into a glass vessel, pour six ounces of boiling water over it, stir well, and allow it to stand for twelve hours. If first-class, it should absorb all the water, and show a thin scum of white glutinous liquid on the top, which will adhere closely to a glass rod or a wooden pencil dipped into it. If the meal does not absorb nearly all the water, it is of inferior quality. The amount of inferiority must be judged by the amount of water not absorbed, and by the character of the fluid on the top of the solution. If it is thin and non-glutinous, the meal is of inferior quality."

LIQUOR ACIDI ARSENOSI. U. S. (Br.) Solution of Arsenous Acid.

(LĪ'QUOR ĂÇ'Ị-DĪ ÄR-SĒ-NŌ'SĪ.)

Liquor Arsenici Hydrochloricus, *Br.;* Liquor Arsenici Chloridi, *U. S. P.* 1870; Hydrochloric Solution of Arsenic, *E.;* Liqueur arsénicale hydrochlorique, *Fr.;* Chlorarsenik-Lösung, *G.*

"Arsenous Acid, *ten grammes* [or 154 grains]; Diluted Hydrochloric Acid, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Diluted Hydrochloric Acid with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Distilled Water, add the Arsenous Acid, and boil the mixture until all the Arsenous Acid is dissolved. Filter the solution, and pass enough Distilled Water through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Arsenious Anhydride, in powder, 87½ *grains* (Imperial) or 10 grammes; Hydrochloric Acid, 2 *fl. drachms* (Imp. meas.) or 12·5 cubic centimetres; Distilled Water, *a sufficient quantity*. Heat the Arsenious Anhydride and the Hydrochloric Acid with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of Distilled Water in a one-pint (or one-litre) flask until a clear solution is obtained; cool; add sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution." *Br.*

This solution is stronger than the Liquor Arsenici Chloridi of the U. S. P. 1870. It contains 4·5 grains of arsenous acid in a fluidounce; the U. S. P. 1870 preparation corresponded in strength with the old British solution (4 grains in a fluidounce). The increase in strength was made in order to make the relation one that would be easy to recollect, namely, 1 per cent. by weight, and the British Pharmacopœia has wisely followed the example, so that both preparations are practically identical. The name has also been changed, as the former title was a misnomer. The hydrochloric acid does not enter into combination with the arsenous acid; it merely aids in its solution. The British title is, in our opinion, to be preferred, because the U. S. name does not indicate the presence of the hydrochloric acid.

Properties. The hydrochloric solution of arsenous acid was first recognized by the U. S. Pharmacopœia at the revision of 1870. According to the British Pharmacopœia, it is "A colorless liquid having an acid reaction. 25 cubic centimetres diluted with *water* should discharge the color of 50·8 to 50·9 cubic centimetres of the *volumetric solution of iodine*, the presence of a slight excess of *sodium bicarbonate* being maintained throughout the operation. 110 minims contain 1 grain of Arsenious Anhydride; 100 cubic centimetres contain 1 gramme." The following test is given in the U. S. P. 1890: "If 24·7 C.c. of Solution of Arsenous Acid be boiled for a few minutes with 2 Gm. of sodium bicarbonate, the liquid cooled, diluted with water to 100 C.c., and mixed with a little starch test-solution, it should require from 49·4 to 50 C.c. of iodine decinormal volumetric solution to produce the blue tint of starch iodide (corresponding to 1 Gm. of arsenous acid in 100 C.c. of the Solution)."

Medical Properties. The medical properties of this solution are the same as those of Fowler's solution, with which it corresponds in strength, being nearly three times as strong as the former London solution of arsenic chloride. Dose, from two to eight minims (0·12–0·5 C.c.).

LIQUOR ACIDI CHROMICI. Br. Solution of Chromic Acid.

(LĪ'QUOR ĂÇ'Ị-DĪ ÇHRŌ'MỊ-CĪ.)

"An aqueous solution containing the equivalent of 25 per cent. of Chromic Anhydride, CrO_3; or 29·5 per cent. of chromic acid regarded as H_2CrO_4." *Br.*

"Chromic Anhydride, 1 *ounce* (Imperial) or 25 grammes; Distilled Water, 3 *fl. ounces* (Imp. meas.) or 75 cubic centimetres. Dissolve." *Br.*

This is officially described as "an orange-red, inodorous, caustic, strongly acid liquid. Specific gravity, 1·185. It should respond to the tests described under 'Acidum Chromicum.'" It is simply a definite solution of chromic acid, and will probably be found convenient as a caustic application. (See p. 43.)

LIQUOR AMMONII ACETATIS. U. S., Br. Solution of Ammonium Acetate. [Spirit of Mindererus.]

(LĪ'QUOR ĄM-MŌ'NỊ-Ī ĂÇ-Ę-TĀ'TĪS.)

"An aqueous solution of Ammonium Acetate [$NH_4C_2H_3O_2 = 76·87$], containing about 7 per cent. of the salt, together with small amounts of acetic and carbonic acids." *U. S.*

Liquor Ammoniæ Acetatis; Liquor Ammonii Acetici, *P. G.;* Acétate d'Ammoniaque liquide, *Fr.;* Essigsaure Ammonium-Lösung, *G.*

"Ammonium Carbonate, *five grammes* [or 77 grains]; Diluted Acetic Acid, *one hundred*

cubic centimeters [or 3 fluidounces, 183 minims]. Add the Ammonium Carbonate (which should be in translucent pieces, free from white, pulverulent bicarbonate) gradually to the cold Diluted Acetic Acid, and stir until it is dissolved. This preparation should be freshly made when wanted." *U. S.*

"Ammonium Carbonate, 1 *ounce* (Imperial) or 50 grammes; Acetic Acid, Distilled Water, of each *a sufficient quantity*. Dissolve the Ammonium Carbonate in ten times its weight of Distilled Water; neutralize with Acetic Acid; add sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution. A little of the Solution, heated in a test-tube to expel carbonic anhydride, should be neutral or only slightly acid to *test-papers*. Solution of Ammonium Acetate should be preserved in a green glass bottle." *Br.*

This preparation is an aqueous solution of ammonium acetate.* The U. S. process by which it is formed involves the decomposition of ammonium carbonate by dilute acetic acid. The formula of commercial ammonium carbonate is complex, but if we consider the salt as neutral carbonate, the reaction is expressed by the following equation: $(NH_4)_2CO_3 + (C_2H_3O_2.H)_2 = (C_2H_3O_2.NH_4)_2 + H_2O + CO_2$. Distilled vinegar was formerly used, but it has been abandoned for diluted acetic acid, which is much to be preferred, because, besides furnishing a solution of the acetate of uniform strength, a result which cannot be attained by the employment of distilled vinegar, it avoids the production of a brownish solution, which uniformly follows the use of the latter, especially when it has been condensed in a metallic worm. The quantity of ammonium carbonate necessary to saturate a given weight of the acid of average strength cannot be laid down with precision, on account of the variable quality of the salt. The preparation, when made with the diluted acetic acid of the U. S. Pharmacopœia, contains about 7 per cent. of ammonium acetate. It is more convenient to add the salt to the acid than to add the acid to the salt, as the point of saturation is thus more easily attained. In ascertaining this point by test-paper, the alkaline reaction will begin, though a portion of free acetic acid may still remain; a little of it being insufficient to overcome the natural alkaline reaction of the salt. A complication is caused by the presence of free carbonic acid, which may be expelled from the liquid towards the end of the saturation by warming it. Supposing it to be free from carbonic acid, the best rule is to cease adding the ammonium carbonate upon the occurrence of the least sign of alkalinity.

The formula of the U. S. P. 1890 differs from that formerly official in dropping what has been called the "mixed solution process." It is to be regretted that the old process of saturating the diluted acetic acid with the ammonium carbonate was not entirely abandoned in the last revision and the process of mixing the solutions alone directed. The separate solutions keep well, and the rapidity and ease with which this preparation can be made by the pharmacist, by simply mixing equal measures of the solutions, are advantages which at once recommend its exclusive use, whilst the physician is more apt to secure a fresh preparation, and one which usually retains a quantity of carbonic acid gas to render the preparation grateful to the patient.

As some pharmacists will prefer to make solution of ammonium acetate in this way, the following process, based on that of the U. S. P. 1880, is offered. Ammonium Carbonate, *one hundred grammes* [or 3 ounces av., 230 grains]; Acetic Acid, *two hundred and seventy cubic centimeters* [or 9 fluidounces, 62 minims]; Distilled Water, *one thousand seven hundred and thirty cubic centimeters* [or 58 fluidounces, 240 minims]. Dissolve the Ammonium Carbonate in *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 60 minims] of Distilled Water, and filter the solution. To the Acetic Acid add *seven hundred and eighty cubic centimeters* [or 26 fluidounces, 180 minims] of Distilled Water. Keep the solutions in separate, well-stopped bottles, and when solution of ammonium acetate is to be dispensed measure equal quantities of each solution and mix them.

The present British process does not differ essentially from ours: in the Br. Pharmacopœia of 1864 the strong solution of ammonia was used instead of the carbonate, and the ammonia combined directly with the acetic acid, without other reaction. There was an advantage in this process in the use of ammonia instead of its carbonate, as the difficulty of ascertaining the precise point of saturation arising from carbonic acid was avoided; but in this solution, as in the neutral mixture, a great benefit remedially is gained by the presence of that acid, which reconciles the stomach to the medicine, and sometimes even allays vomiting in febrile diseases. With this view of the subject it is better to use ammonium carbonate; the change has been made in the present Br. Pharmacopœia, but the advantages are practically lost because the

* For method of making dry ammonium acetate, see *A. J. P.*, 1875, 25.

solution is nearly always made in advance of actual use, and official solution of ammonium acetate is rarely sparkling, but as generally dispensed it has a flat, mawkish taste quite in contrast with that made by the "mixed solution process."

Properties. Solution of ammonium acetate, when made of pure materials, is "a clear, colorless liquid, free from empyreuma, of a mildly saline, acidulous taste, and an acid reaction. It is wholly volatilized by heat. When Solution of Acetate of Ammonium is heated with potassium or sodium hydrate, vapor of ammonia is evolved. When heated with sulphuric acid, the Solution gives off vapor of acetic acid." *U. S.* When it contains an excess of alkali, its taste is bitterish. It should be freshly prepared at short intervals, as its acid becomes decomposed and a portion of ammonium carbonate is generated. When pure it is not precipitated by barium chloride. Silver nitrate precipitates crystals of silver acetate, soluble in water, and especially in nitric acid. An insoluble precipitate with this test is silver chloride, and shows the presence of hydrochloric acid. Potassa disengages ammonia; sulphuric acid, acetous vapors. When evaporated to dryness, the residue is wholly dissipated by heat, with the smell of ammonia. It is incompatible with acids, the fixed alkalies and their carbonates, lime water, magnesia, magnesium sulphate, corrosive sublimate, the iron, copper, and zinc sulphates, and silver nitrate. When it contains free carbonic acid, it produces with lead acetate or subacetate a precipitate of lead carbonate, which, being mistaken for the sulphate, has sometimes led to the erroneous conclusion that sulphuric acid was present in the distilled vinegar, when this has been employed. *Ammonium acetate* is a salt of difficult crystallization, and very deliquescent. When perfect it probably has an alkaline reaction, like potassium and sodium acetates. It may be obtained by sublimation from a mixture of equal parts of dry potassium or calcium acetate and ammonium chloride, or, according to Berthelot, by dissolving glacial acetic acid in ammonia, keeping the retort cool, and adding enough water to prevent the crystallization of the salt during the neutralization; the solution is then evaporated in a current of dry, gaseous ammonia until the liquid solidifies on cooling. It is then introduced into a large capsule, and this placed upon caustic lime, under a large bell-glass, in which a considerable quantity of ammonia gas is injected. After a few days the crystalline mass is broken, and the capsule replaced as before upon lime in an ammoniacal atmosphere, under the bell-glass. When this operation has been repeated several times, a perfectly pure ammonium acetate is obtained, which crystallizes in large needles, like potassium nitrate, and resembling ammonium formate; it is extremely soluble in water, and does not possess an acid reaction. (*A. J. P.*, 1875, p. 25.) It is formed by the union of one molecule of acetic acid, $H.C_2H_3O_2$, with one group, NH_4, from $NH_4.OH$, the hydrate, or $(NH_4)_2CO_3$, the carbonate. When evaporated to dryness, however, it readily yields an acid salt, $C_2H_3O_2.NH_4 + C_2H_4O_2$. The molecular weight of the normal salt is 77.

Medical Properties and Uses. Solution of ammonium acetate is a valuable diaphoretic, much employed in febrile diseases. If, instead of promoting its determination to the skin by external warmth, the patient walk about in a cool air, its action will be directed to the kidneys. In large doses, it is said to relieve *painful menstruation*. It is sometimes used externally as a discutient. Mixed in the quantity of a fluidounce with seven fluidounces of rose-water and two fluidrachms of laudanum, it forms a useful collyrium in *chronic ophthalmia*. The late Dr. A. T. Thomson used it as a lotion with good effect in *porrigo* affecting the scalp. The dose is from half a fluidounce to a fluidounce and a half (15–45 C.c.) every three or four hours, mixed with water and sweetened with sugar. It proves sometimes very grateful to febrile patients when prescribed with an equal measure of carbonic acid water.

LIQUOR AMMONII CITRATIS. Br. Solution of Ammonium Citrate.

(LĪ'QUOR ĄM-MŌ'NI-Ī CĪ-TRĀ'TĪS.)

Citrate d'Ammoniaque liquide, *Fr.;* Citronensaure Ammoniak-Flüssigkeit, *G.*

"Ammonium Carbonate, 1¾ *ounces* (Imperial) or 87·5 grammes or a sufficient quantity; Citric Acid, 2½ *ounces* (Imp.) or 125 grammes; Distilled Water, *a sufficient quantity*. Dissolve the Citric Acid in five times its weight of Distilled Water; neutralize with Ammonium Carbonate; add sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution. A little of the Solution, heated in a test-tube to expel carbonic anhydride, should be neutral or only slightly acid to *test-papers*. Solution of Ammonium Citrate should be preserved in a green glass bottle." *Br.*

This solution may be used for the same purposes as Solution of Ammonium Acetate, in the dose of from two to six fluidrachms (7·5–22·5 C.c.).

LIQUOR ARSENI ET HYDRARGYRI IODIDI. U. S. (Br.) Solution of Arsenic and Mercuric Iodide. [Donovan's Solution.]

(LĪ'QUOR ÄR'SE-NĪ ĔT HĬ-DRÄR'GY-RĪ Ī-ŏD'I-DĪ.)

Liquor Arsenii et Hydrargyri Iodidi, *Br.*, Solution of Arsenious and Mercuric Iodides; Liquor Arsenici et Hydrargyri Iodidi, *Br.* 1867, *U. S.* 1870; Solution of Hydriodate of Arsenic and Mercury; Solutio Donovani; Soluté d'Iodo-arsénite de Mercure, Liqueur de Donovan, *Fr.*; Jodquecksilber Arsenik-Lösung, Donovan'sche Tropfen, *G.**

"Arsenic Iodide, *ten grammes* [or 154 grains]; Red Mercuric Iodide, *ten grammes* [or 154 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Powder the Arsenic Iodide, and mix it with the Red Mercuric Iodide by trituration. Add *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Distilled Water, and continue the trituration until solution is effected. Filter the solution, and pass enough Distilled Water through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.*

"Arsenious Iodide, 87½ *grains* (Imperial) or 10 grammes; Mercuric Iodide, 87½ *grains* (Imp.) or 10 grammes; Distilled Water, *a sufficient quantity*. Triturate the Arsenious Iodide and Mercuric Iodide with *three* to *four fluid ounces* (Imp. meas.) or one hundred and fifty to two hundred cubic centimetres of the Distilled Water until nearly all is dissolved; pass through a filter; wash the latter with sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution. A clear pale yellow liquid with a metallic taste. It affords the reactions characteristic of mercuric salts, arsenium, and iodides. 110 minims correspond to 1 grain of Arsenious Iodide, AsI_3, and to 1 grain of Mercuric Iodide, HgI_2; 100 cubic centimetres correspond to 1 gramme of each salt." *Br.*

This solution was introduced to the notice of the medical profession in 1839 by Mr. Donovan, of Dublin, as a therapeutic agent combining the medical virtues of its three ingredients, and was adopted as an official preparation in the U. S. and Dublin Pharmacopœias of 1850. It was dropped from the British Pharmacopœia of 1867, but reintroduced in the 1885 revision, and fortunately made to correspond in strength with the U. S. preparation,—namely, 1 per cent. of each of the active ingredients. The formula of the U. S. Pharmacopœia is the simplified one of Prof. Procter, which consists essentially in dissolving equal weights of arsenic teriodide and mercuric iodide (red iodide) in a measured quantity of distilled water. The change in the quantities of the two salts from the process of the U. S. P. 1870 is very trifling. The proportion of equal weights corresponds nearly to single molecules of the component iodides.

Properties. This solution has a pale-yellow color and a slightly styptic taste. Sometimes, however, the color is orange-yellow, owing to the presence of free iodine. This may be recombined by rubbing the solution with a little metallic mercury or arsenic, in fine powder, and the proper hue be thus restored. The solution is incompatible with laudanum and the soluble salts of morphine. On the supposition that it is an aqueous solution of iodides, it will contain them in the proportion of one mol. of arsenic teriodide 456, to one of mercuric iodide 454, which are nearly equal weights. The British solution has the sp. gr. 1·016.

Medical Properties. This preparation has been found decidedly useful as an alterative in various diseases of the skin, such as the different forms of *psoriasis*, *impetigo*, *porrigo*, *lepra*, *pityriasis*, *lupus*, and *venereal eruptions*, both papular and scaly. In *chronic rheumatism* and in advanced specific diseases, especially "*night pains*," it is often useful. The dose is from five to ten drops (0·3–0·6 C.c.) three times a day, given preferably in distilled water.

LIQUOR ATROPINÆ SULPHATIS. Br. Solution of Atropine Sulphate.

(LĪ'QUOR ĂT-RO-PĪ'NÆ SŬL-PHĀ'TĬS.)

"Atropine Sulphate, 17½ *grains* (Imperial) or 1 gramme; Salicylic Acid, 2 *grains* (Imp.) or 0·12 gramme; Distilled Water, 4 *fl. ounces* (Imp. meas.) or 100 cubic centimetres or a

* *Clemens's Solution. Arsenic bromide* was introduced as a remedy in diabetes by Clemens. It is best administered in the form of a solution, which has been prepared by Mr. R. F. Fairthorne according to the following formula: "77 grains of metallic arsenic in powder are added in small portions to 240 grains of bromine, the latter being placed in a long test-tube immersed in ice-water to control the otherwise violent reaction. One hundred grains of the tribromide obtained are dissolved in sufficient distilled water to make ten fluidounces. One minim will then contain one-forty-eighth of a grain." According to Clemens, the commencing dose of such a solution is one minim three times a day, increased gradually until the equivalent of one-fifth of a grain of the salt is daily exhibited. The clinical reports in regard to this remedy in *diabetes* seem to indicate that along with a restricted diet it is occasionally of distinct service, but in the majority of instances fails to accomplish good. (See, also, *Liquor Potassii Arseniatis et Bromidi*, National Formulary, PART II.)

sufficient quantity. Dissolve the Atropine Sulphate and Salicylic Acid in sufficient recently boiled and cooled Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the solution. 110 minims contain 1 grain of Atropine Sulphate; 100 cubic centimetres contain 1 gramme." *Br.*

This solution contains 1 per cent. of atropine sulphate. Camphor water was substituted for distilled water on account of its antiseptic properties at the 1885 revision. Salicylic acid and distilled water are now used (1899) with the same object in view. The dose is one minim.

LIQUOR BISMUTHI ET AMMONII CITRATIS. Br. Solution of Bismuth and Ammonium Citrate.

(LĪ'QUOR BĬS-MŪ'THĪ ĔT ĄM-MŌ'NĮ-Ī CĪ-TRĀ'TĬS.)

Liquor Bismuthi; Soluté de Citrate de Bismuth ammoniacal, *Fr.*; Citronensaure Wismuth-Ammoniak-Lösung, *G.*

" Bismuth Oxynitrate, 613 *grains* (Imperial) or 70 grammes; Potassium Citrate, 613 *grains* (Imp.) or 70 grammes; Potassium Carbonate, 175 *grains* (Imp.) or 20 grammes; Nitric Acid, 1 *fl. ounce* (Imp. meas.) or 50 cubic centimetres; Solution of Ammonia, Distilled Water, of each *a sufficient quantity*. Dissolve the Bismuth Oxynitrate in the Nitric Acid diluted with an equal volume of Distilled Water; add Distilled Water with constant stirring until the liquid is very faintly opalescent; add the Potassium Citrate and Carbonate dissolved in a little Distilled Water; heat the liquid to the boiling point; cool; separate the precipitate; wash it with Distilled Water until free from nitrates. Gradually add Solution of Ammonia to the moist precipitate until it is just dissolved; dilute with Distilled Water to *one pint* (Imp. meas.) or one thousand cubic centimetres; filter." *Br.*

The British Pharmacopœia (1898) adopted a new process for this preparation, which is a modification of Bartlett's process. (See below.) An acid solution of bismuth is treated with a solution of potassium citrate and potassium carbonate, the precipitate washed and dissolved in solution of ammonia, and then diluted with water in proper proportions. (See *Bismuthi et Ammonii Citras*, p. 269.)

Some years since, a secret preparation was made and sold by Mr. Schacht, of Clifton, England, under the name of *Liquor Bismuthi*. Mr. Ch. R. C. Tichborne, having analyzed the liquid and found it to contain bismuth oxide, ammonia, and citric acid, announced the discovery at a meeting of the Pharmaceutical Society, when Mr. Schacht, being present, acknowledged the correctness of the analysis, stating, at the same time, that he had never made a secret of the composition of his solution to medical practitioners, and that a fluidrachm of his liquid contained one grain of the teroxide. (*P. J. Tr.*, 1864, p. 301.) A formula for the preparation was given by Mr. Tichborne, which, however, on repeated trial by Mr. N. Gray Bartlett, of Chicago, proved to be impracticable. After numerous experiments, Mr. Bartlett succeeded in making a solution which had all the desired qualities. (See *A. J. P.*, Jan. 1865.) He first prepares a *bismuth citrate* by dissolving a *troyounce* of bismuth subcarbonate in 720 *grains* of nitric acid, diluting the solution after effervescence has ceased with *a fluidounce and a half* of distilled water gradually introduced, and then adding this solution, slowly and with constant stirring, to another solution made by dissolving 600 *grains* of potassium citrate in *two pints* of distilled water. By an interchange, potassium nitrate and bismuth citrate are formed, the latter of which, being insoluble, is precipitated, and is obtained by throwing the whole upon a filter, thoroughly washing the salt with distilled water, and then drying it on bibulous paper with a gentle heat. The next step is to prepare the *bismuth and ammonium citrate*. This is done by rubbing the bismuth citrate with sufficient distilled water to make a paste, and adding to this gradually, and with constant trituration, stronger ammonia water until the citrate is dissolved, care being taken to avoid an excess of ammonia. The solution is now filtered, and spread on glass to dry.

Various modifications of Mr. Bartlett's process have been suggested, though it may be doubted whether any one, on the whole, is preferable to the original. Besides the processes offered by Mr. T. P. Blunt and Mr. Tichborne, in England, Mr. A. E. Ebert and Prof. Markoe have each proposed a modification of Mr. Bartlett's process. (See *A. J. P.*, 1866, p. 1, and 1869, p. 151.) In Ebert's formula the solution of bismuth nitrate is decomposed by caustic potassa in the presence of citric acid, instead of the potassium citrate already formed; in Markoe's, crystallized sodium carbonate is substituted for the caustic alkali, to which various objections exist. After precipitating the solution of bismuth nitrate to which citric acid has been added, with sodium carbonate, washing the precipitate to get rid of the sodium nitrate,

and dissolving the residue of the precipitate in ammonia water, Markoe completes the process by determining the proportion of bismuth teroxide contained in the solution, and then diluting the liquid so that each fluidrachm shall contain one grain of teroxide. For other methods of making this solution, see 17th ed. U. S. D., 794.

The British Pharmacopœia describes this preparation as "A colorless solution, with a slightly metallic taste. Specific gravity 1·070. Slightly alkaline to *test-paper;* is freely miscible with *water;* heated with alkalies evolves ammonia, and yields a white precipitate. Evaporated to dryness and the product ignited, a residue with a yellow edge results, which when suitably treated should not yield any reaction characteristic of silver, lead, copper, arsenium, iron, selenium, or tellurium. A mixture of 10 cubic centimetres of the Solution with 40 cubic centimetres of *water*, treated with *hydrogen sulphide* in excess, yields a black precipitate, which, when washed and dried, should weigh at least 0·55 gramme. 1 fluid drachm contains an amount of bismuth equivalent to about 3 grains, or 1 cubic centimetre the equivalent of 0·05 gramme, of Bismuth Oxide."

Bismuth and ammonium citrate, obtained by Mr. Bartlett's process, is in fine, glossy, translucent, colorless scales, of a slightly acidulous, somewhat metallic, not disagreeable taste, very soluble in water, but not deliquescent, and of an acid reaction. (See page 269.) From an analysis by Mr. Bartlett, it appears to possess the formula $Bi,C_6H_5O_7,NH_3 + 3H_2O$. Rother, however (1876), considers that the formula should be written $C_6H_5O_7(NH_4)_3Bi(OH)_3$.

There is no occasion for a permanent solution of this salt, as it may at any time be dissolved when wanted for use. But, as it is in the liquid form that it has obtained its present reputation, we give a formula for a permanent solution prepared by Mr. Bartlett. Dissolve 260 *grains* of bismuth and ammonium citrate in *fourteen fluidounces* of distilled water, neutralize the solution with ammonia water, and add *two fluidounces* of alcohol. The solution of the salt without addition is liable to spontaneous decomposition; but, in the opinion of Mr. Bartlett, it is completely protected by the ammonia and alcohol, so that in this state it will keep indefinitely.

Medical Properties and Uses. This preparation is much more astringent than are the insoluble salts of bismuth, and is at the same time irritant, and not possessed of the peculiar medical properties which grow out of the insolubility of the subnitrate or subcarbonate. It is, therefore, not a substitute for these, and is adapted to the treatment of *diarrhœas* of relaxation rather than of irritation. Dose of the solution, from one-half to one fluidrachm (1·9–3·75 C.c.).

LIQUOR CALCIS. U. S., Br. Solution of Lime. [Solution of Calcium Hydrate. Lime Water.]

(LĪ'QUOR CAL'CĪS.)

"A saturated, aqueous solution of Calcium Hydrate [$Ca(OH)_2 = 73·83$]. The percentage of Calcium Hydrate varies with the temperature, being somewhat over 0·17 per cent. at 15° C. (59° F.), and diminishing as the temperature rises." *U. S.*

Aqua Calcis; Aqua Calcariæ, *P. G.;* Eau Liqueur de Chaux, *Fr.;* Kalkwasser, *G.*

"Lime, *twelve grammes* [or 185 grains]; Distilled Water, *a sufficient quantity.* Slake the Lime by the gradual addition of *seventy cubic centimeters* [or 2 fluidounces, 176 minims] of Distilled Water, then add *three hundred and sixty cubic centimeters* [or 12 fluidounces, 83 minims] more of Distilled Water, and agitate occasionally during half an hour. Allow the mixture to settle, decant the liquid and throw it away. Then add to the residue *thirty-six hundred cubic centimeters* [or 121 fluidounces, 350 minims] of Distilled Water, agitate thoroughly, wait a short time for the coarser particles to subside, and pour the liquid, holding the undissolved Lime in suspension, into a glass-stoppered bottle. From time to time shake the bottle, so as to keep the solution saturated. Pour off the clear liquid when it is wanted for use." *U. S.*

"Calcium Hydroxide, 2 *ounces* (Imperial) or 50 grammes; Distilled Water, *a sufficient quantity.* Wash the Calcium Hydroxide with Distilled Water until free from chlorides; then shake it with *one gallon* (Imp. meas.) or four litres of Distilled Water in a stoppered green glass bottle for two or three minutes; set aside for twelve hours. The clear Solution may be drawn off with a siphon as it is required for use, and should then be transferred to a green glass bottle." *Br.*

A solution of calcium hydrate, $Ca(OH)_2$, in water is the result of these processes. By the slaking of the lime it is reduced to powder, and rendered more easily diffusible through the water. According to both Pharmacopœias, the solution is to be kept in bottles with a portion of undissolved hydrate, which causes it always to be saturated whatever may be the tempera-

ture and to whatever extent it may be exposed to the air. If care be taken to have a considerable quantity of the solution in the bottle, and to avoid unnecessary agitation, the upper portion will always remain sufficiently clear for use. The employment of distilled water as the solvent may seem a useless refinement; but in many places the common water is very impure. Water dissolves but a minute proportion of lime, and, contrary to the general law, less when hot than when cold. Hence the propriety of employing cold water in the process. According to Mr. Phillips, a pint of water (the wine pint of the U. S. P. 1870) at 212° F. dissolves 5·6 grains of lime, at 60° F. 9·7 grains, and at 32° F. 11·0 grains. For Green's automatic device for dispensing lime water in excellent condition, see *Proc. A. P. A.*, 1893, 474.

Properties. Lime water is "a clear, colorless liquid, without odor, and having a saline and feebly caustic taste. It absorbs carbon dioxide from the air, so that a pellicle of calcium carbonate forms on the surface of the liquid. On being heated, it becomes turbid from separation of calcium hydrate, which redissolves again when the liquid is cooled. It gives a strongly alkaline reaction with litmus paper. The alkaline reaction of the Solution should entirely disappear, after it has been saturated with carbon dioxide, and subsequently boiled (absence of *alkalies* and *their carbonates*). In other respects it should conform to the reactions and tests given under Lime (see *Calx*). 50 C.c. of Solution of Lime should require, for complete neutralization, about 20 C.c. of oxalic acid decinormal volumetric solution (corresponding to about 0·14 (0·148) per cent. of Calcium Hydrate), phenolphtalein being used as indicator." *U. S.* Exposed to the air it attracts carbonic acid, and becomes covered with a pellicle of insoluble calcium carbonate, which, subsiding after a time, is replaced by another, and so on successively till the whole of the lime is exhausted. Hence the necessity of keeping lime water either in closely-corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime. "24 cubic centimetres should require for neutralization 10 cubic centimetres of the *decinormal volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead or for chlorides. 1 fluid ounce contains the equivalent of about ½ grain, or 1000 cubic centimetres rather more than 1 gramme, of Lime, CaO." *Br.*

Medical Properties and Uses. Lime water is antacid, tonic, and astringent, and is very usefully employed in *dyspepsia* with acidity of stomach, *diarrhœa*, *diabetes*, and *gravel* attended with superabundant secretion of uric acid. Mixed with an equal measure of milk, which completely covers its offensive taste, it is one of the best remedies in our possession for nausea and vomiting dependent on irritability of stomach. We have found a diet exclusively of lime water and milk to be more effectual than almost any other plan of treatment in *dyspepsia* accompanied with vomiting of food. In this case one part of the solution to two or three parts of milk is usually sufficient. Externally it is employed as a wash in *tinea capitis* and *scabies*, as an application to foul and gangrenous *ulcers*, as an injection in *leucorrhœa* and *ulceration of the bladder* or *urethra*, and, mixed with linseed or olive oil, as a liniment in *burns* and *scalds*. Having been found to possess the property of dissolving false membrane, it has naturally been employed as a local remedy in *pseudo-membranous croup*. There are two methods of applying the remedy: one by directing lime water spray, produced by the atomizer, so that it shall be inhaled by the patient; the other by causing the patient to inhale freely the vapors arising from lime undergoing the process of slaking with water. The dose of lime water is from two to four fluidounces (60–118 C.c.) several times a day. When employed to allay *nausea*, it is usually given in the dose of a tablespoonful mixed with the same quantity of milk, and repeated at intervals of half an hour, an hour, or two hours. If too long continued it debilitates the stomach. The urine of persons who take large quantities of lime water is often alkaline, and sometimes distinctly ammoniacal. According to the researches of John J. Abel, this is due to the presence in the urine of calcium carbamate, which is prone to undergo ammoniacal disintegration.

LIQUOR CALCIS CHLORINATÆ. Br. Solution of Chlorinated Lime.

(LĪ'QUOR CĂL'CĬS ĊHLŌ-RĮ-NĀ'TÆ.)

Chlorure de Chaux liquide, *Fr.*; Chlorkalk-Flüssigkeit, *G.*

"Chlorinated Lime, 1 *pound* (Imperial) or 500 grammes; Distilled Water, 1 *gallon* (Imp. meas.) or 5 litres. Mix; transfer the mixture to a stoppered bottle: set aside for three hours, shaking occasionally; filter through calico. Preserve the filtrate in a stoppered bottle in a cool, dark place." *Br.*

For the properties and uses of this preparation, see *Calx Chlorinata*. The British Pharmacopœia gives the following test of its strength: "Specific gravity about 1·055. Each gramme

mixed with 0·5 gramme of *potassium iodide* dissolved in *water*, when acidulated with 1 cubic centimetre of *hydrochloric acid*, gives a brownish-red solution which requires for the discharge of its color not less than 5·6 cubic centimetres of the *volumetric solution of sodium thiosulphate*, corresponding to 2 per cent. of available chlorine. The Solution should yield, when fresh, about 3 per cent. of available chlorine." This determines its strength in chlorine, by determining the quantity of iodine which the chlorine contained in it is capable of separating from potassium iodide. Notwithstanding, however, that a test of its character is thus given by the Pharmacopœia, its strength must vary according to the quality of the chlorinated lime employed. It is one of the best antidotes for hydrogen sulphide, ammonium sulphydrate, potassium sulphide, and hydrocyanic acid. The dose for internal use is from twenty minims to a fluidrachm (1·23–3·69 C.c.). For external application the solution may be diluted with twice its bulk of water, or may be used of the full strength in some cutaneous affections.

LIQUOR CALUMBÆ CONCENTRATUS. Br. Concentrated Solution of Calumba.

(LĪ'QUOR CA-LŬM'BÆ CŎN-CĔN-TRĀ'TŬS.)

"Calumba Root, in No. 5 powder, 10 *ounces* (Imperial) or 500 grammes; Alcohol (90 per cent.), 4½ *fl. ounces* (Imp. meas.) or 225 cubic centimetres; Distilled Water, 20 *fl. ounces* (Imp. meas.) or 1000 cubic centimetres or a sufficient quantity. Macerate the Calumba for twenty-four hours with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of Distilled Water; press strongly; again macerate the residue for twenty-four hours with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of Distilled Water; press strongly. Mix the expressed liquids, and heat for five minutes to 180° F. (82·2° C.). When cold add the Alcohol; set aside; decant or filter, adding sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Concentrated Solution." *Br.*

This is a new preparation of the British Pharmacopœia. It should, in our opinion, be named "*Infusum Calumbæ Concentratum*," as it is nothing more than a concentrated infusion, preserved with alcohol, and intended to be used by the pharmacist for the quick preparation of the infusion of calumba by dilution with water. It is ten times as strong as the ordinary infusion. The dose is from one-half to one fluidrachm (1·9 to 3·75 C.c.).

LIQUOR CAOUTCHOUC. Br. Solution of India-rubber.

(LĪ'QUOR CAŎUT'CHŎUC.)

"India-rubber, 1 *ounce* (Imperial) or 50 grammes; Benzol, 10 *fl. ounces* (Imp. meas.) or 500 cubic centimetres; Carbon Bisulphide, 10 *fl. ounces* (Imp. meas.) or 500 cubic centimetres. Cut the India-rubber into fine shreds, and place it in a well-stoppered bottle containing the previously mixed Benzol and Carbon Bisulphide. Set aside in a cool place, and agitate occasionally until solution is effected." *Br.*

This solution is an improvement on the solution of gutta-percha formerly official; it was introduced into the Br. Pharm. (1898) mainly for use in the preparation of mustard paper. It may be used like collodion as an external protective application.

LIQUOR CHIRATÆ CONCENTRATUS. Br. Concentrated Solution of Chiretta.

(LĪ'QUOR ȻHĮ-RĀ'TÆ CŎN-CĔN-TRĀ'TŬS.)

"Chiretta, in No. 40 powder, 10 *ounces* (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 *fl. ounces* (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Chiretta with *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This is a "concentrated" infusion of the Br. Ph. (1898), intended to be used by the pharmacist for making the ordinary infusion of chiretta by dilution with water. It is twenty times as strong as the infusion of chiretta (Br. Ph., 1885). The dose is from one-half to one fluidrachm (1·9 to 3·75 C.c.).

LIQUOR CUSPARIÆ CONCENTRATUS. Br. Concentrated Solution of Cusparia.

(LĪ'QUOR CŪS-PĀ'RI-Æ CŎN-CĔN-TRĀ'TŬS.)

"Cusparia Bark, in No. 40 powder, 10 *ounces* (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 *fl. ounces* (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Cusparia with *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This is a concentrated infusion of the Br. Pharm. 1898, intended to be used by the pharmacist for making infusion of cusparia by dilution with water. It is ten times as strong as the infusion of cusparia (Br. Pharm. 1885). The dose is from one-half to one fluidrachm (1·9 to 3·75 C.c.).

LIQUOR EPISPASTICUS. Br. Blistering Liquid.

(LĪ'QUOR ĔP-I-SPĂS'TI-CŬS.)

Linimentum Cantharidis; Huile de Cantharides térébenthinée, *Fr.;* Spanischfliegen-Liniment, *G.*

"Cantharides, in No. 20 powder, 10 *ounces* (Imperial) or 500 grammes; Acetic Ether, *a sufficient quantity.* Mix the Cantharides with *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of Acetic Ether; pack in a percolator; at the expiration of twenty-four hours pour Acetic Ether over the contents of the percolator; allow the solution to pass slowly through until *one pint* (Imp. meas.) or one thousand cubic centimetres of the Liquid is obtained. This preparation is twice the strength of the Blistering Liquid of the British Pharmacopœia of 1885." *Br.* This liquid is used in making the British Blistering Collodion. (See p. 439.)*

LIQUOR ETHYL NITRITIS. Br. Solution of Ethyl Nitrite.

(LĪ'QUOR Ē'THĬL NĪ-TRĪ'TĪS.)

"A mixture of ninety-five parts by volume of Absolute Alcohol with five parts by volume of Glycerin, containing when freshly made 3 per cent. by weight, and even when long kept not less than 2½ per cent. by weight of ethyl nitrite. The ethyl nitrite is obtained by the interaction of alcohol (90 per cent.), sodium nitrite, and diluted sulphuric acid, at a low temperature." *Br.*

This is a new official preparation of the Br. Ph. 1898; it might be called improved spirit of nitrous ether. It is difficult to explain the reason for its introduction without the dismissal of spirit of nitrous ether; the strength is very slightly greater than that of the spirit, and a choice should have been made between them. The addition of glycerin as a preservative, and the substitution of absolute alcohol for rectified spirit, are relied upon to make a permanent solution. This method was proposed by Dunston and Dymond (*P. J. Tr.*, 1888, 861), who believe that ethyl nitrite is the *sole* valuable constituent in spirit of nitrous ether; glycerin prevents loss of the very volatile ethyl nitrite, whilst the absence of water is secured by the use of absolute alcohol, water in the alcohol being shown to be the principal cause of decomposition and loss of ethyl nitrite. Solution of ethyl nitrite was strongly recommended by Prof. Leech, and the advantage claimed for it is that it is free from aldehyde. The increased cost, due to the use of absolute alcohol, will be apt to prevent the extensive use of the Solution. It is described as "A limpid liquid, practically colorless, of characteristic apple-like odor and taste. It is highly inflammable. Specific gravity 0·823 to 0·826. When Solution of Ethyl Nitrite is poured on an acidulated strong solution of *ferrous sulphate* contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two liquids, widening as the tube is gently shaken. The Solution should not effervesce when shaken carefully with *sodium bicarbonate* (absence of acid). 10 cubic centimetres, mixed with 5 cubic centi-

* Very nearly corresponding to this preparation is the *Linimentum Cantharidis*, or *Cantharides Liniment*, of the U. S. P. 1880. Made according to the formula, it is a very active counter-irritant, when too freely applied producing deep vesication. "Cantharides, in No. 60 powder, *fifteen parts* [or one ounce av.]; Oil of Turpentine, *a sufficient quantity*, To make *one hundred parts* [or half a pint]. Digest the Cantharides with *one hundred parts* [or half a pint] of Oil of Turpentine, in a closed vessel, by means of a water-bath, for three hours; then strain and add enough Oil of Turpentine through the strainer to make the Liniment weigh *one hundred parts* [or measure half a pint.]" *U. S.* 1880.

metres of the *volumetric solution of sodium hydroxide* and 5 cubic centimetres of *water*, should not assume a yellow color (absence of aldehyde). 1 volume, agitated briskly at intervals during five minutes in a brine-charged nitrometer with 1 volume of *solution of potassium iodide* and 1 volume of *diluted sulphuric acid*, should yield, at the ordinary temperature (60° F. or 15·5° C.) and pressure (30 inches or 760 millimetres of mercury), and when freshly prepared, at least 7·6 volumes of nitric oxide gas; and even after the Solution has been kept for some time, and the vessel containing it has occasionally been opened, it should possess at least five-sixths of the strength just indicated. Solution of Ethyl Nitrite should be stored in small bottles." *Br.* This preparation affords a means of giving ethyl nitrite internally. The dose is from twenty to sixty minims (1·25 to 3·75 C.c.). (See *Spiritus Ætheris Nitrosi.*)

LIQUOR FERRI ACETATIS. U. S., Br. Solution of Ferric Acetate.

(LĪ'QUOR FĔR'RĪ ĂÇ-Ę-TĀ'TĬS.)

"An aqueous solution of Ferric Acetate [$Fe_2(C_2H_3O_2)_6 = 464{\cdot}92$], containing about 31 per cent. of the anhydrous salt, and corresponding to about 7·5 per cent. of metallic iron." *U. S.*

Solution of Acetate of Iron; Solution of Peracetate of Iron; Liquor Ferri Acetici, *P. G.;* Liqueur d'Acétate de Fer, *Fr.;* Essigsaure Eisen-Flüssigkeit, *G.*

"Solution of Ferric Sulphate, *one thousand grammes* [or 35 ounces av., 120 grains]; Glacial Acetic Acid, *two hundred and sixty grammes* [or 9 ounces av., 75 grains]; Ammonia Water, *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims]; Water, Distilled Water, each, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the Ammonia Water with *three thousand cubic centimeters* [or 101 fluidounces, 213 minims] of cold Water, and the solution of Ferric Sulphate with *ten thousand cubic centimeters* [or 338 fluidounces, 70 minims] of cold Water. Add the latter solution slowly to the diluted Ammonia Water, stirring constantly. Let the mixture stand until the precipitate has subsided as far as practicable, and then decant the supernatant liquid. Add to the precipitate *six thousand cubic centimeters* [or 202 fluidounces, 426 minims] of boiling Water, mix well, and again set the mixture aside, as before. Repeat the washing with successive portions of boiling Water, in the same manner, until the washings are no longer affected by sodium cobaltic nitrite test-solution (showing the removal of ammonia and its salts). Transfer the mixture to a wet muslin strainer, allow the precipitate to drain completely, and press it, folded in the strainer, until its weight is reduced to *seven hundred grammes* [or 24 ounces av., 303 grains] or less. Now add the precipitate gradually to the Glacial Acetic Acid contained in a tared jar provided with a glass stopper, stirring the mixture after each addition until each portion added is nearly dissolved before adding another portion. Finally, add enough Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains], mix thoroughly, allow it to become clear by subsidence, and decant the clear solution. Keep the product in well-stoppered bottles, in a cool place, protected from light." *U. S.*

"Solution of Ferric Sulphate, 2½ *fl. ounces* (Imperial measure) or 125 cubic centimetres; Solution of Ammonia, 4 *fl. ounces* (Imp. meas.) or 200 cubic centimetres or a sufficient quantity; Glacial Acetic Acid, liquefied, 1½ *fl. ounces* (Imp. meas.) or 75 cubic centimetres; Distilled Water, *a sufficient quantity.* Mix the Solution of Ammonia with *one pint* (Imp. meas.) or one litre of Distilled Water; gradually add to this the Solution of Ferric Sulphate diluted with *one pint* (Imp. meas.) or one litre of Distilled Water; stir well together, taking care that ammonia is, even finally, in slight excess, as indicated by the odor of the mixture; let the whole stand for two hours, stirring occasionally; transfer it to a calico filter; wash the precipitated ferric hydroxide with Distilled Water until free from sulphates; let it drain; squeeze it to remove superfluous moisture; dissolve it in the Glacial Acetic Acid; make the volume up to *one pint* (Imp. meas.) or one litre with Distilled Water; allow any insoluble matter to subside; pour off the clear Solution." *Br.*

The formula of this preparation is practically identical with that of the solution of iron acetate of the German Pharmacopœia. The U. S. and British processes consist in first forming ferric hydrate, by precipitating a solution of ferric sulphate with ammonia water, washing and draining the precipitate, and finally dissolving it in glacial acetic acid. The solution is readily effected in the cold, and no heat whatever should be used, to avoid decomposition. It is impossible to prevent change, however, by time, an insoluble precipitate invariably making its appearance. The German Pharmacopœia directs diluted acetic acid; and its *Liquor Ferri Subacetici* is not so strong as our official solution, having only the sp. gr. 1·087 to 1·091, corresponding to 5 per cent. of iron. The British preparation (sp. gr. 1·031) is still

weaker. The strong solution of acetate of iron (Br. Ph. 1885) is no longer official. (See *U. S. D.*, 17th ed., 798.)

Properties. The official solution is described as "a dark reddish-brown, clear liquid, of an acetous odor, a sweetish, acidulous, somewhat styptic taste, and a slightly acid reaction. Specific gravity, about 1·160 at 15° C. (59° F.). The diluted Solution yields a brownish-red precipitate with ammonia water, and a blue one with potassium ferrocyanide test-solution. When heated to boiling, the Solution yields a brownish-red precipitate, and when heated with sulphuric acid, it emits acetous vapors. If the iron be completely precipitated from a portion of the Solution by an excess of ammonia water, the filtrate should be colorless, and should not yield a white or dark-colored precipitate with hydrogen sulphide test-solution (absence of *zinc* or *copper*), nor should it leave a residue on evaporation and gentle ignition (absence of *salts of the fixed alkalies*). If to a small portion of the Solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferricyanide test-solution be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of *ferrous salt*). If 1·12 (1·1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 C.c.), together with 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 15 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 0·5 per cent. of metallic iron)." *U. S.* "A red liquid with a sour styptic taste and acetous odor, miscible with *water* and *alcohol* (90 per cent.) in all proportions. It affords the reactions characteristic of ferric salts and of acetates. It should not yield any characteristic reaction with the tests for lead, copper, arsenium, zinc, calcium, sodium, potassium, ammonium, nitrates, or ferrous salts, and only very slight reactions with the tests for sulphates. Specific gravity 1·031." *Br.*

Medical Properties. Ferric Acetate is an excellent chalybeate: this strong solution is not, however, quite so well adapted for internal administration as is the Tincture of Ferric Acetate or the Solution of Iron and Ammonium Acetate. Although it was introduced for the purpose of making the former preparation, it may be serviceable when mixed with water, with the addition of an aromatic syrup. The dose is from two to ten minims (0·12–0·6 C.c.).

LIQUOR FERRI CHLORIDI. U. S. (Br.) Solution of Ferric Chloride.

(LĪ'QUOR FĔR'RĪ ĊHLŌ'RĮ-DĪ.)

"An aqueous solution of Ferric Chloride [$Fe_2Cl_6 = 323·98$], containing about 37·8 per cent. of the anhydrous salt, corresponding to 62·9 per cent. of the crystallized salt [$Fe_2Cl_6 + 12H_2O = 539·5$], or to about 13 per cent. of metallic iron." *U. S.*

Liquor Ferri Perchloridi Fortis, *Br.*, Strong Solution of Ferric Chloride, Solution of Chloride of Iron; Liquor Ferri Sesquichlorati, *P. G.;* Soluté de Perchlorure de Fer, Chlorure ferrique liquide, *Fr.;* Flüssiges Eisenchlorid, *G.*

"Iron, in the form of fine, bright wire, and cut into small pieces, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Hydrochloric Acid, *eight hundred and seventy grammes* [or 30 ounces av., 301 grains]; Nitric Acid, Distilled Water, each, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Introduce the Iron Wire into a flask having a capacity of about *two thousand cubic centimeters* [or 67 fluidounces, 302 minims], pour upon it a mixture of *five hundred and forty grammes* [or 19 ounces av., 21 grains] of Hydrochloric Acid and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Distilled Water, and let the mixture stand in a moderately warm place until effervescence ceases; then heat it to the boiling point, filter it through paper, and, having rinsed the flask and Iron Wire with a little hot Distilled Water, pass the rinsings through the filter. To the filtered liquid add *two hundred and eighty grammes* [or 9 ounces av., 384 grains] of Hydrochloric Acid, add the mixture slowly and gradually, in a stream, to *eighty grammes* [or 2 ounces av., 360 grains] of Nitric Acid contained in a capacious porcelain vessel, and warm gently. After effervescence ceases, apply heat, by means of a sand-bath, until the liquid is free from nitrous odor. Then test a few drops of the liquid, diluted with water, with freshly prepared potassium ferricyanide test-solution. Should this reagent produce a blue color, add a little more Nitric Acid, drop by drop, as long as effervescence is observed, and evaporate off the excess. Finally, add the remaining *fifty grammes* [or 1 ounce av., 334 grains] of Hydrochloric Acid and enough Distilled Water to make the solution weigh *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

"Iron, 4 *ounces* (Imperial) or 80 grammes; Hydrochloric Acid, 20½ *fl. ounces* (Imp. meas.) or 410 cubic centimetres; Nitric Acid, 1½ *fl. ounces* (Imp. meas.) or 30 cubic centimetres; Distilled Water, *a sufficient quantity*. Place the Iron in a flask; add a mixture of *twelve and a half fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of Hydrochloric Acid and *seven* [*fluid*] *ounces* (Imp. meas.) or one hundred and forty cubic centimetres of Distilled Water; expose to a moderate temperature until effervescence ceases; then boil; filter from undissolved Iron; rinse the flask and contents with a little Distilled Water; pour the rinsings over the filter; add to the filtrate *seven fluid ounces* (Imp. meas.) or one hundred and forty cubic centimetres of Hydrochloric Acid; mix; pour the solution in a slow continuous stream into the Nitric Acid, chemical action being promoted if necessary by the application of slight heat; evaporate the product until no more nitrous fumes escape and a precipitate begins to form; add *one fluid ounce* (Imp. meas.) or twenty cubic centimetres of Hydrochloric Acid, and sufficient Distilled Water to produce *seventeen and a half fluid ounces* (Imp. meas.) or three hundred and fifty cubic centimetres of the Solution." *Br.* (See *Liquor Ferri Perchloridi*, p. 804.)

By the reaction between the hydrochloric acid and the iron, ferrous chloride is produced, which by the subsequent agency of the hydrochloric and nitric acids is converted into ferric chloride, or, as it is denominated in the British Pharmacopœia, perchloride of iron, this being retained in solution by the water with the excess of acid. This preparation was included in the original British Pharmacopœia, but was not official with us until 1870. The original British formula (1864) was defective in several respects. For an account of these see the 13th edition of this book. The formula for the present British solution has been modelled after that of the U. S. Pharmacopœia.

When iron is treated with hydrochloric acid there is a copious evolution of hydrogen, and an emerald-green solution of ferrous chloride ($FeCl_2$) results. Green crystals having the composition $FeCl_2,4H_2O$ separate if the solution is permitted to rest. In the official process, water is added to the hydrochloric acid in order to retain the crystals in solution, and the mixture is heated whilst still in contact with the excess of iron, in order to hasten the complete conversion of all the hydrochloric acid into ferrous chloride. The action slackens very materially as the quantity of hydrochloric acid is gradually lessened in the mixture, but when it is brought, as officially directed, to the boiling point, a saturated solution is produced. After filtering from the excess of iron, half the original quantity of hydrochloric acid is added,—this for the purpose of supplying the amount which is requisite to form the solution of ferric chloride,—and the mixture is then gradually poured into nitric acid, which at once converts the solution of green ferrous chloride into the solution of red ferric chloride. Formerly the nitric acid was added to the solution; now the order is reversed, in accordance with the recommendation of Prof. C. L. Diehl, to prevent frothing. (See *A. J. P.*, 1867, p. 140.) The reaction may be thus expressed:

$$\underset{\text{Ferrous chloride.}}{6FeCl_2} + \underset{\text{Nitric acid.}}{2HNO_3} + \underset{\text{Hydrochloric acid.}}{6HCl} = \underset{\text{Ferric chloride.}}{3Fe_2Cl_6} + \underset{\text{Nitrogen dioxide.}}{N_2O_2} + \underset{\text{Water.}}{4H_2O}.$$

If the solution should have a blackish color, and not a clear ruby-red, it is due to the presence of a nitro-compound composed of a portion of ferrous chloride and nitrogen dioxide, $FeCl_2 + N_2O_2$. As this compound is easily decomposed, all that is necessary is to heat the liquid and add a few drops of nitric acid, when the blackish color soon disappears, nitrogen dioxide is liberated, and a ruby-red solution remains. Any excess of nitric acid is to be evaporated away.* The final addition of hydrochloric acid is to compensate for any loss which may

* The use of chlorine instead of nitric acid for converting the ferrous chloride to the ferric condition is advocated by C. W. Weisse (*Pharm. Zeitung; N. R.*, 1883, p. 247), and Mr. J. W. England has devised the following process, based upon such substitution, which is alleged to furnish a purer product:

"Take of Iron, in the form of fine wire, and cut in small pieces, 15 parts (3¾ oz. av.); Hydrochloric Acid, 59 parts (14¾ oz. av.); Chlorine Gas, Distilled Water, each, a sufficient quantity to make 100 parts (25 oz. av.). Place the Iron Wire in a capacious flask, and pour upon it 54 parts (13½ oz. av.) of Hydrochloric Acid, previously diluted with 25 parts (6¼ oz. av., or 6 fluidounces) of Distilled Water. Heat the liquid slowly, until the reaction is ended, and effervescence ceases; then rapidly heat to the boiling point, filter through paper, and, having rinsed the flask and residue with a little boiling distilled water, pass the washings through the filter. To the filtrate add immediately 5 parts (1¼ oz. av.) of Hydrochloric Acid, followed by the addition of 20 parts (5 oz. av.) of boiling Distilled Water. Keep the liquid nearly boiling, and pass through it a stream of gaseous chlorine (generated in the usual way), agitating occasionally, until a small portion, tested with freshly-prepared potassium ferricyanide test-solution, gives no indication of the existence of a ferrous compound by producing a blue precipitate. Lastly, add, after any free chlorine present has been removed by heat, sufficient distilled water to make the whole product weigh 100 parts (25 oz. av.)." (*A. J. P.*, 1885, p. 113.) Mr. August Drescher (*Drug. Circ.*, 1887, p. 4) proposes the use of hydrogen dioxide (H_2O_2), now an article of commerce, as a substitute for either nitric acid or chlorine.

have been suffered by heating the solution, and to secure an excess of the acid in the finished preparation; otherwise a reddish-brown deposit of oxychloride would gradually form, and precipitation would result upon dilution with alcohol in making the official tincture.

The solution of ferric chloride, properly made, is "a reddish-brown liquid, having a faint odor of hydrochloric acid, an acid, strongly styptic taste, and an acid reaction. Specific gravity, about 1·387 at 15° C. (59° F.). The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide test-solution, and a white one, insoluble in nitric acid, with silver nitrate test-solution. If the iron be completely precipitated from a portion of the Solution by an excess of ammonia water, the filtrate should be colorless, and should not yield a white or a dark-colored precipitate with hydrogen sulphide test-solution (absence of *zinc* or *copper*); nor should it leave a fixed residue on evaporation and gentle ignition (absence of *salts of the fixed alkalies*). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a moderately dilute portion of the Solution, the crystal should not become colored brown, nor should there be a brownish-black color developed around it (absence of *nitric acid*). If to a diluted portion of the Solution a few drops of freshly prepared potassium ferricyanide test-solution be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of *ferrous salt*). On diluting 1 C.c. of the Solution, with water, to 40 C.c., and boiling, the liquid should remain clear (absence of *oxychloride*). If 1·12 (1·1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 C.c.), together with 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 26 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 0·5 per cent. of metallic iron)." *U. S.* Water and alcohol unite with it in all proportions. The British preparation is stronger than the U. S. official, the sp. gr. of the former being 1·420, of the latter 1·387. "An orange-brown solution with a strong styptic taste, miscible with *water* and *alcohol* in all proportions. It affords the reactions characteristic of ferric salts and chlorides, and should not yield any characteristic reaction with the tests for lead, copper, arsenium, zinc, calcium, sodium, potassium, ammonium, nitrates, or ferrous salts. Specific gravity about 1·42. 5 cubic centimetres of it diluted with 80 cubic centimetres of *water* should give, upon the addition of an excess of *solution of ammonia*, a reddish-brown precipitate, which, when well washed and incinerated, weighs 1·6 grammes. 110 minims contain 22½ grains of Iron; 100 cubic centimetres contain 22·5 grammes." *Br.*

From the experiments of M. Adrian it appears that sugar has the property when mixed in certain proportions with solution of ferric chloride of converting it partly into ferrous chloride. The alteration commences immediately on the addition of sugar, as shown by the deeper color of the liquid; after some hours potassium ferricyanide will indicate the presence of a ferrous salt; and after twenty-four hours the greater proportion of the ferric salt has undergone the change.* (*Bost. Med. and Surg. Journ.*, March, 1868.) (See *Liquor Ferri Protochloridi*, PART II., National Formulary.)

Medical Uses. This preparation was brought prominently into notice by M. Pravaz, a surgeon of Lyons, who found that a few drops of a strong solution, injected into a blood-vessel, produced coagulation of all the blood in the vessel for the extent of an inch or more. Its use as a styptic was the natural result of this observation. In this capacity it has been used in the cure of *varices*, and has even been recommended as an injection in ordinary *aneurisms*. In arresting hemorrhages from cut surfaces or wounded vessels it has proved remarkably suc-

* The solution of ferric chloride, when kept, has a disposition to deposit the insoluble oxychloride of iron, and the resulting excess of hydrochloric acid is injuriously irritating. To obviate this disadvantage, M. Burin du Buisson recommends the following mode of preparation. "Saturate as quickly as possible pure and colorless hydrochloric acid with [gelatinous] hydrated ferric oxide; evaporate the solution to somewhat less than one-half over a gentle fire; and then continue the evaporation by means of the salt-bath, taking care to remove the aqueous vapors, which would cause the formation of hydrochloric acid, and a deposition of insoluble oxychloride. When the solution has attained the consistence of thick syrup (in which state it curdles on cooling, without, however, becoming a solid mass), cease evaporating, add an excess of the gelatinous hydrate diluted with a little water, agitate for a quarter of an hour, and afterwards allow the liquor to rest for several hours. Next add distilled water sufficient to bring the solution to the density of 30° Baumé, and allow it to stand for eight days in contact with an excess of the hydrate; after which filter, and again allow it to stand for two weeks." This strength of the solution is required for the cure of *varices*. For injection into *aneurismal tumors* it is sufficient to employ a solution of 20° or even 15°. These degrees of Baumé are equivalent—30° to 29·70 per cent. of the dry salt, 20° to 17·05 per cent., and 15° to 12·10 per cent. (See *Ferri Chloridum*, U. S., page 607.)

cessful. It has also been found advantageous as an application to *nasal polypi*, *erectile tumors*, or *nævi materni* in infants, in *ulcers* about the nails, and in various cutaneous affections. (See *Ferric Chloride*.) Attempts have been made to cure *nævi materni* by the injection of the solution into the erectile tumor; but this proceeding is hazardous: a fatal result is recorded as having occurred in an infant a month old. Five drops of the solution, introduced into the centre of the tumor, were followed instantly by a sharp cry, a brief convulsion, and death. (*Ann. de Thérap.*, 1867, p. 117.) Several other similar cases have occurred. Injection of it in *cystic goitre* has been strongly recommended by Dr. Morell Mackenzie (*London Lancet*, May 11, 1872), and has also been practised with advantage by some other surgeons. It has been used externally with asserted success in *varicose veins*. It may be used internally, properly diluted, for the general purposes of chalybeates, and especially as a substitute for the tincture of ferric chloride, when the alcohol of that preparation is objectionable. For ordinary purposes the dose is from two to ten minims (0·12–0·6 C.c.). In *post-partum hemorrhage* it has been largely employed, a solution of it, varying in strength from a drachm to a half-ounce to the pint, being thrown directly into the relaxed uterus. It is used in the preparation of the tincture of ferric chloride.

LIQUOR FERRI CITRATIS. U. S. Solution of Ferric Citrate.

(LĪ'QUOR FĔR'RĪ CĪ-TRĀ'TĬS.)

"An aqueous solution of Ferric Citrate, corresponding to about 7·5 per cent. of metallic iron." *U. S.*

Solution of Citrate of Iron; Liquor Ferri Citrici; Citrate de Fer liquide, *Fr.*; Flüssiges Eisencitrat, *G.*

"Solution of Ferric Sulphate, *one thousand and fifty grammes* [or 37 ounces av., 16 grains]; Citric Acid, *three hundred grammes* [or 10 ounces av., 255 grains]; Ammonia Water, *eight hundred and eighty cubic centimeters* [or 29 fluidounces, 363 minims]; Water, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the Ammonia Water with *three thousand cubic centimeters* [or 101 fluidounces, 213 minims] of cold Water, and the Solution of Ferric Sulphate with *ten thousand cubic centimeters* [or 338 fluidounces, 70 minims] of cold Water. Add the latter solution slowly to the diluted Ammonia Water, with constant stirring. Pour the mixture on a wet muslin strainer, and allow the liquid to run off and the precipitate to drain. Then remove the moist mass from the strainer, mix it well with *six thousand cubic centimeters* [or 202 fluidounces, 426 minims] of cold Water, again pour it on the strainer, and let it drain. Repeat this washing with several successive portions of cold Water in the same manner, until the washings cease to produce more than a slight cloudiness with barium chloride test-solution. Then allow the precipitate to drain completely, transfer it to a porcelain capsule, add the Citric Acid, and heat the mixture, on a water-bath, to 60° C. (140° F.), stirring constantly, until the precipitate is dissolved. Lastly, filter the liquid, and evaporate it, at the above-mentioned temperature, until it weighs *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

In this process, the ferric hydrate is first obtained by treating solution of ferric sulphate with ammonia, and is then combined, by the aid of heat, with the citric acid, thus forming a solution of ferric citrate. It might appear, from the phraseology of the process, that in the direction to add the citric acid to the precipitated hydrate, the addition of water to hold the resulting citrate in solution had been omitted; but the precipitate, even after draining, retains mechanically quite sufficient water for the purpose, so much, indeed, that evaporation is necessary at the end of the process to reduce the bulk to the required standard. The temperature is limited to 60° C. (140° F.), because, though a moderate heat promotes the solution, a high degree of it diminishes the solubility of the oxide, and thus interferes with the process.

The solution is "a dark brown liquid, odorless, and possessing a slightly ferruginous taste. Specific gravity, about 1·250 at 15° C. (59° F.). Upon evaporating 100 Gm. of the Solution, in a thin layer, on plates of glass, about 42·5 to 43 Gm. of garnet-red scales will be obtained. The Solution has an acid reaction upon litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide test-solution it affords a bluish-green color or precipitate, which is increased and rendered dark blue by the subsequent addition of hydrochloric acid. On heating the Solution with potassium or sodium hydrate test-solution, it will yield a brown precipitate, without evolving vapor of *ammonia*. If a portion of the Solution, diluted with 4 volumes of water, be deprived of its iron by boiling it with an excess of potassium or sodium hydrate test-solution, and the filtrate slightly acidulated with acetic acid, a portion of this liquid, when allowed to stand for some time, should not give a

white, crystalline precipitate (absence of *tartrate*). If to another portion of the acidulated and cooled filtrate a little calcium chloride test-solution be added, and the liquid heated to boiling, it should gradually deposit a white, crystalline precipitate. If 1·12 (1·1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 C.c.), together with 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 15 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 0·5 per cent. of metallic iron)." *U. S.* It keeps for a long time without change, and answers admirably well for preparing solid ferric citrate and the chalybeate salts containing it, and for introducing it into extemporaneous mixtures. Each fluidounce of it contains about half a troyounce of ferric citrate. It may be given as a ferruginous tonic, in the dose of ten minims (0·6 C.c.), equivalent to five grains (0·33 Gm.) of the salt, several times a day.

LIQUOR FERRI ET AMMONII ACETATIS. U. S. Solution of Iron and Ammonium Acetate.

[Mistura Ferri et Ammonii Acetatis, Pharm. 1880. Basham's Mixture.]

(LĪ'QUOR FĔR'RĪ ĔT ĄM-MŌ'NĮ-Ī ĂÇ-Ę-TĀ'TĬS.)

"Tincture of Ferric Chloride, *twenty cubic centimeters* [or 325 minims]; Diluted Acetic Acid, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Solution of Ammonium Acetate, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Aromatic Elixir, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Glycerin, *one hundred and twenty cubic centimeters* [or 4 fluidounces, 28 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. To the Solution of Ammonium Acetate (which should not be alkaline) add, successively, the Diluted Acetic Acid, the Tincture of Ferric Chloride, the Aromatic Elixir, and the Glycerin, and, lastly, enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. This preparation should be freshly made, when wanted." *U. S.*

The first name of this preparation has been changed to "Liquor" in accordance with the views expressed in the 16th edition of this work, as it belongs to the class of solutions, and is not a mixture in the modern acceptation of the term. The formula has been improved by the addition of glycerin, which enables the solution to remain undecomposed somewhat longer: it should be borne in mind, however, that this was never intended to be a permanent solution, and in time precipitation and decomposition surely set in. Some pharmacists adopt the plan of keeping all the ingredients, except the tincture of ferric chloride and water, mixed together in advance, and when called upon to dispense the solution, to add the proper quantity of tincture and water; this saves time and enables them to dispense a clear solution. When freshly made, it is a transparent, bright red liquid. When cloudy, the absence of sufficient free acid is indicated. The iron is in the form of an acetate, whilst there is formed, as one of the products of decomposition, a small quantity of ammonium chloride, the larger proportion of ammonium acetate remaining undecomposed. Basham's mixture is actively chalybeate, and also astringent, and is very largely used in *chronic Bright's disease*. The dose is from one-half to one fluidounce (15–30 C.c.).

LIQUOR FERRI NITRATIS. U. S. (Br.) Solution of Ferric Nitrate.

(LĪ'QUOR FĔR'RĪ NĪ-TRĀ'TĬS.)

"An aqueous solution of Ferric Nitrate [$Fe_2(NO_3)_6 = 483·1$], containing about 6·2 per cent. of the anhydrous salt, and corresponding to about 1·4 per cent. of metallic iron." *U. S.*

Liquor Ferri Pernitratis, *Br.;* Solution of Pernitrate of Iron; Solution of Nitrate of Iron; Azotate (Pernitrate) de Fer liquide, *Fr.;* Salpetersaure Eisenoxyd-Lösung, *G.*

"Solution of Ferric Sulphate, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Ammonia Water, *one hundred and sixty cubic centimeters* [or 5 fluidounces, 197 minims]; Nitric Acid, *seventy-one grammes* [or 2 ounces av., 220 grains]; Distilled Water, Water, each, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the Ammonia Water with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of cold Water, and the Solution of Ferric Sulphate with *fifteen hundred cubic centimeters* [or 50 fluidounces, 345 minims] of cold Water. Add the latter solution slowly to the diluted Ammonia Water, with constant stirring. Let the mixture stand until the precipitate has subsided as far

as practicable, and then decant the supernatant liquid. Add to the precipitate *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of cold Water, mix well, and again set the mixture aside, as before. Repeat the washing with successive portions of cold Water, in the same manner, until the washings produce but a slight cloudiness with barium chloride test-solution. Pour the washed ferric hydrate on a wet muslin strainer, and let it drain thoroughly. Then transfer it to a porcelain capsule, add the Nitric Acid, and stir with a glass rod, until a clear solution is obtained. Finally, add enough Distilled Water to make the finished product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Filter, if necessary." *U. S.*

"Iron, 1 *ounce* (Imperial) or 20 grammes; Nitric Acid, 4½ *fl. ounces* (Imp. meas.) or 90 cubic centimetres; Distilled Water, *a sufficient quantity*. Dilute the Nitric Acid with *sixteen* [*fluid*] *ounces* (Imp. meas.) or three hundred and twenty cubic centimetres of the Distilled Water; introduce the Iron; set aside until the metal is dissolved, taking care to moderate the action, should it become too violent, by the addition of a little more Distilled Water; filter the liquid; add enough Distilled Water to produce *thirty fluid ounces* (Imp. meas.) or six hundred cubic centimetres of the Solution." *Br.*

Solution of ferric nitrate was made in the U. S. P. 1870 by first forming ferrous nitrate by dissolving iron wire in diluted nitric acid, and then converting this into ferric nitrate by heating with an additional quantity of nitric acid; there was a slight excess of nitric acid left in the solution (about 1·4 per cent.). It was believed by the Committee of Revision that a solution of more definite composition would be made by adopting Mr. Louis Dohme's process. In this, ferric hydrate is dissolved in nitric acid in such proportion that the solution of ferric nitrate shall contain 6·2 per cent. of the anhydrous salt when assayed by the official process, and about 1 per cent. of free nitric acid.*

The U. S. solution is "a clear amber-colored or reddish liquid, odorless, having an acid, styptic taste, and an acid reaction. Specific gravity, about 1·050 at 15° C. (59° F.). The Solution gives a brownish-red precipitate with ammonia water, and a blue one with potassium ferrocyanide test-solution. If a clear crystal of ferrous sulphate be added to a cooled mixture of equal parts of the Solution and of concentrated sulphuric acid, the crystal will become brown and be surrounded by a brownish-black zone. If 1·12 (1·1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 C.c.), together with 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 2·8 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 0·5 per cent. of metallic iron)." *U. S.* It contains no ferrous nitrate, and does not give a blue precipitate with potassium ferricyanide. The British preparation is described as "A clear solution of a reddish-brown color, distinctly acid and astringent to the taste. It affords the reactions characteristic of ferric salts and of nitrates. It should not yield any characteristic reaction with the tests for lead, copper, arsenium, zinc, calcium, sodium, potassium, ammonium, chlorides, sulphates, or ferrous salts. Specific gravity 1·107. 5 cubic centimetres treated with an excess of *solution of ammonia* should give a precipitate which, when washed, dried, and incinerated, weighs 0·23 gramme. 110 minims contain 3½ grains of Iron; 100 cubic centimetres contain 3·3 grammes." It is, therefore, about twice as strong as the U. S. solution.

Ferric nitrate is somewhat deliquescent, very soluble in water, and sparingly soluble in nitric acid. It consists of the double atom of iron, Fe_2, which is hexatomic, combined with 6 groups, NO_3, and crystallizes either with 12 molecules of water in colorless cubes, or with 18 molecules of water in colorless monoclinic crystals, yielding, therefore, either $Fe_2(NO_3)_6 + 12H_2O$ or $Fe_2(NO_3)_6 + 18H_2O$.

Medical Properties. This solution was introduced to the notice of the profession by Mr. William Kerr, in 1832. Its virtues are those of a tonic and astringent. Dr. R. J. Graves, of Dublin, praises it as a remedy in *chronic diarrhœa*, especially when occurring in delicate and nervous women, in which there is no thirst, redness of tongue, tenderness of the abdomen on pressure, or other indication of inflammation. It is considered particularly applicable to the treatment of *mucous diarrhœa* attended with pain, but not to cases in which ulcerations of the intestines exist; but in our experience it has seemed to be irritating, and has generally failed to accomplish good. It has also been used with alleged good effect in *menorrhagia*, and both

* *Syrup of Ferrous Nitrate* may be prepared by Prof. Procter's formula. (See *U. S. D.*, 16th ed., p. 903.)

internally and by injection in *leucorrhœa*, when occurring in pale, exsanguine, and feeble subjects; it should be sufficiently diluted to cause only a slight heat and smarting in the vagina. The dose, according to Dr. Graves, is seven or eight drops (0·36 or 0·42 C.c.), gradually increased to fifteen (0·85 C.c), sufficiently diluted, given in the course of the day. Dr. Garrod and Mr. Squire state the dose of the British preparation, though twice as strong in iron as our own, at from thirty minims to a fluidrachm (1·9–3·75 C.c.). Considering that a fluidrachm of the British solution contains 7·865 grains of the salt, this appears to us a very large dose.

LIQUOR FERRI PERCHLORIDI. Br. Solution of Perchloride of Iron.

(LĪ'QUOR FĔR'RĪ PĔR-ȻHLŌ'RĮ-DĪ.)

Solution of Ferric Chloride.

"Strong Solution of Ferric Chloride, 5 *fl. ounces* (Imperial measure) or 250 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the Strong Solution of Ferric Chloride with sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of this Solution of Ferric Chloride." *Br.* (See p. 799.)

This is one-fourth the strength of the *Liquor Ferri Perchloridi* of the Br. Pharmacopœia of 1864, which is the *Liquor Ferri Perchloridi Fortis* of the present edition. (See p. 799.) It is of the same ferruginous strength as the British tincture of Ferric Chloride. The specific gravity of this solution is 1·110, and it may be substituted for the tincture of ferric chloride when alcohol is objectionable; it is very astringent, and is perhaps less active as a diuretic than the tincture. Dose, from ten to thirty minims (0·65–1·9 C.c.) well diluted.

LIQUOR FERRI SUBSULPHATIS. U. S. Solution of Ferric Subsulphate.

[Solution of Basic Ferric Sulphate. Monsel's Solution.]

(LĪ'QUOR FĔR'RĪ SŬB-SŬL-PHĀ'TĪS.)

"An aqueous solution of Basic Ferric Sulphate (of variable chemical composition), corresponding to about 13·6 per cent. of metallic iron." *U. S.*

Solution of Subsulphate of Iron; Solution of Persulphate of Iron; Liqueur hémostatique de Monsel, *Fr.*; Basisch-schwefelsaure Eisenoxydlösung, Monsel's Eisenlösung, *G.*

"Ferrous Sulphate, in clear crystals, *six hundred and seventy-five grammes* [or 23 ounces av., 354 grains]; Sulphuric Acid, *sixty-five grammes* [or 2 ounces av., 128 grains]; Nitric Acid, Distilled Water, each, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Add the Sulphuric Acid to *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Distilled Water in a capacious porcelain capsule, heat the mixture to nearly 100° C. (212° F.), then add *sixty-five grammes* [or 2 ounces av., 128 grains] of Nitric Acid, and mix well. Divide the Ferrous Sulphate, coarsely powdered, into four equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. When all of the Ferrous Sulphate is dissolved, add a few drops of Nitric Acid, and, if this causes a further evolution of red fumes, continue to add Nitric Acid, a few drops at a time, until it no longer causes red fumes to be evolved; then boil the Solution until it assumes a ruby-red color and is free from nitrous odor. Lastly, add enough Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Keep the product in well-stoppered bottles, in a moderately warm place (not under 22° C. or 71·6° F.), protected from light. This solution will sometimes crystallize, forming a semi-solid, whitish mass. When this occurs, the application of a gentle heat to the bottle will restore the liquid condition. Solution of Ferric Subsulphate is to be dispensed when Solution of Persulphate of Iron has been prescribed by the physician." *U. S.*

This process is essentially that of Dr. Squibb. The object is to obtain in solution *Monsel's Persulphate of Iron*, improperly so called, as it differs both in composition and in properties from the salt of iron properly named persulphate. The composition of the true persulphate is $Fe_2(SO_4)_3$, and it is a neutral salt, while Monsel's persulphate has the composition $Fe_4O(SO_4)_5$,* and is properly a subsalt, as it is very appropriately designated in the U. S. Pharmacopœia. With this preliminary explanation, the process will be easily understood.

In its preparation the ferrous sulphate is converted into ferric sulphate at the expense of the nitric acid; but the sulphuric acid, mixed with the nitric, is in quantity insufficient to form

* Mr. Spencer U. Pickering believes that the true composition of basic ferric sulphate is represented by the formula $Fe_2(SO_4)_3,5Fe_2O_3.H_2O$. (See *Journ. Chem. Soc.*, xliii. 182.)

the normal salt. The sesquioxide is therefore but partially saturated, and a subsalt results, having the constitution above mentioned.*

The solution of ferric subsulphate is "a dark reddish-brown liquid, odorless or nearly so, of an acid, strongly styptic taste, and an acid reaction. Specific gravity, about 1·550 at 15° C. (59° F.). Miscible with water and alcohol, in all proportions, without decomposition. The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide test-solution, and a white one, insoluble in hydrochloric acid, with barium chloride test-solution. On slowly mixing 2 volumes of the Solution with 1 volume of concentrated sulphuric acid, in a beaker, a semi-solid, white mass will separate on standing (difference from *tersulphate*). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Solution, the crystal should not become brown, nor should there be a brownish-black color developed around it (absence of *nitric acid*). If to a small portion of the Solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferricyanide test-solution be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of *ferrous salt*). If 1·12 (1·1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 C.c.), together with 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 27·2 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 0·5 per cent. of metallic iron)." *U. S.* A little sulphuric acid decolorizes the liquid in a considerable degree, and an excess of the same acid converts it into a white, soft, pasty solid, resembling plaster of Paris which has begun to solidify after mixture with water. This test, according to Dr. Squibb, is quite characteristic. (*N. Y. Journ. of Med.*, 1860, p. 173.)

By evaporation, upon a glass surface, with a moderate heat, the solution yields ferric subsulphate, or *Monsel's salt*, in the form of thin transparent scales, of a light reddish-brown color, deliquescent, and readily soluble in water. Attention was first called to the special styptic virtues of ferric sulphate by M. Monsel in 1852; but it was not until 1857 that he published the formula for the peculiar salt which now goes by his name, and the solution of which is the subject of the present article. (See *Journ. de Pharm.*, Sept. 1857, and Juillet, 1859.)

In consequence of its deficiency of sulphuric acid, this salt is less irritant than the ferric sulphate, while it has at least equal, if not greater, astringency. It is therefore very efficacious as a styptic, and peculiarly adapted, through its power of coagulating the blood, to cases of *hemorrhage* from incised wounds, or from surfaces in which it is specially desirable to avoid irritation. It is said also to have been found peculiarly efficacious in *chancre*. The solution may be applied by means of a small sponge or pencil of spun glass to the bleeding surface or vessel. In cases of *hæmoptysis*, a dilution of it (from five to ten minims to the fluidounce) has been used with advantage, by means of the atomizer. It is an excellent styptic in *hemorrhage* from the stomach and bowels, in doses of from three to six minims (0·18–0·36 C.c.), properly diluted, and repeated as often as necessary.

LIQUOR FERRI TERSULPHATIS. U. S. (Br.) Solution of Ferric Sulphate.

(LĪ'QUOR FĔR'RĪ TĔR-SŬL-PHĀ'TĬS.)

"An aqueous solution of normal Ferric Sulphate [$Fe_2(SO_4)_3 = 399{\cdot}22$], containing about 28·7 per cent. of the salt, and corresponding to about 8 per cent. of metallic iron." *U. S.*

Liquor Ferri Persulphatis, *Br.;* Liquor Ferri Sulfurici Oxydati, *P. G.;* Solution of Tersulphate of Iron; Solution of Persulphate of Iron; Persulfate de Fer liquide, *Fr.;* Flüssiges Schwefelsaures Eisenoxyd, *G.*

* Mr. J. Creuse offers the following formulæ for the preparation of the solutions of *ferric sulphate* and *ferric subsulphate*, holding them to be superior to the official because they require no especial apparatus and generate no noxious vapors:

For the ferric sulphate, Take of Ferrous Sulphate, in coarse powder, twelve troyounces; Sulphuric Acid two troyounces and sixty grains; Potassium Chlorate three hundred and forty-eight grains; Boiling Water twelve fluidounces. Dissolve the ferrous sulphate in the boiling water in a glass matrass, or in any convenient bottle; add the sulphuric acid gradually, and, while the liquid is hot, add the potassium chlorate by small portions. When all is dissolved, filter, and complete twenty-four fluidounces. The following formula explains the reaction: $6(FeSO_4) + 3H_2SO_4 + KClO_3 = 3(Fe_2(SO_4)_3 + 3H_2O + KCl$.

For the subsulphate, Take of the ingredients above enumerated, respectively, twelve troyounces, one troyounce and thirty grains, three hundred and forty grains, ten fluidounces; proceed as before; evaporate to twelve fluidounces, and filter. (*A. J. P.*, xliii. 169.) The solutions thus obtained are contaminated with potassium chloride.

"Ferrous Sulphate, in clear crystals, *four hundred grammes* [or 14 ounces av., 48 grains]; Sulphuric Acid, *seventy-eight grammes* [or 2 ounces av., 328 grains]; Nitric Acid, Distilled Water, each, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Add the Sulphuric Acid to *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Distilled Water in a capacious porcelain capsule, heat the mixture to nearly 100° C. (212° F.), then add *fifty-five grammes* [or 1 ounce av., 411 grains] of Nitric Acid, and mix well. Divide the Ferrous Sulphate, coarsely powdered, into four equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until the effervescence ceases. When all of the Ferrous Sulphate is dissolved, add a few drops of Nitric Acid, and, if this causes a further evolution of red fumes, continue to add Nitric Acid, a few drops at a time, until it no longer causes red fumes to be evolved; then boil the Solution until it assumes a reddish-brown color and is free from nitrous odor. Lastly, add enough Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Filter, if necessary." *U. S.*

"Ferrous Sulphate, 8 *ounces* (Imperial) or 400 grammes; Sulphuric Acid, 6 *fl. drachms* (Imp. meas.) or 37·5 cubic centimetres; Nitric Acid, 6 *fl. drachms* (Imp. meas.) or 37·5 cubic centimetres; Distilled Water, *a sufficient quantity*. Add the Sulphuric Acid to *ten* [*fluid*] *ounces* (Imp. meas.) or five hundred cubic centimetres of the Distilled Water; dissolve the Ferrous Sulphate in the mixture with the aid of heat; mix the Nitric Acid with *two* [*fluid*] *ounces* (Imp. meas.) or one hundred cubic centimetres of the Distilled Water; add to this diluted acid, warmed, the solution of Ferrous Sulphate; concentrate by boiling, until, by the sudden disengagement of ruddy vapors, the liquid ceases to be black and acquires a red color. If any ferrous salt remain in the solution, add a few drops of Nitric Acid, and boil again. When the solution is cold, make up the quantity to *eleven fluid ounces* (Imp. meas.) or five hundred and fifty cubic centimetres by the addition, if necessary, of Distilled Water." *Br.*

The ferrous sulphate is directed to be in clear crystals, meaning by this "not effloresced," because when the crystals are coated with a whitish powder they have lost water of crystallization, and the proportion of iron present is variable. The nitric acid in the process gives up enough of its oxygen to convert it entirely into ferric sulphate, and the effervescence is owing to the escape of nitrogen dioxide; this becomes red nitrogen tetroxide by contact with the air. The conversion of the ferrous salt into ferric salt is incomplete until the effervescence ceases, and the color, from black, as it was at first, has become reddish brown. Indeed, in order to convert the whole into ferric sulphate it is necessary to continue the heat until nitrous odor ceases to be evolved, and thus the entire absence of nitric or nitrous acid from the solution is insured. But in consequence of the higher oxidation of the iron the sulphuric acid of the sulphate is insufficient to saturate it. Enough sulphuric acid, therefore, is added to meet this demand. The process is completed by adding enough water to make a definite weight. The U. S. and British formulas are the same in principle; but in the latter the additional precaution is taken, in order to insure the complete change of ferrous into ferric salt, of testing the liquid with potassium ferricyanide, which will produce a blue precipitate so long as any of the ferrous sulphate remains. The solution, prepared according to the U. S. formula, is "a dark reddish-brown liquid, almost odorless, having an acid, strongly styptic taste, and an acid reaction. Specific gravity, about 1·320 at 15° C. (59° F.). Miscible with water and alcohol, in all proportions, without decomposition. The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide test-solution, and a white one, insoluble in hydrochloric acid, with barium chloride test-solution. On slowly mixing 2 volumes of the Solution with 1 volume of concentrated sulphuric acid, in a beaker, no solid, white mass will separate on standing (difference from *subsulphate*). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a moderately diluted portion of the Solution, the crystal should not become brown, nor should there be a brownish-black color developed around it (absence of *nitric acid*). If to a small portion of the Solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferricyanide test-solution be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of *ferrous salt*). If 1·12 (1·1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 C.c.), together with 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 16 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or

greenish color of the liquid (each C.c. of the volumetric solution indicating 0·5 per cent. of metallic iron)." The solution, diluted with water, gives a white precipitate with barium chloride, showing that it contains a sulphate. It keeps well; and we have seen a specimen made by the U. S. 1870 process, ten years old, which retained all its properties unchanged and had deposited nothing. It is described in the Br. Pharmacopœia as "A dense solution of a dark red color, inodorous and very astringent, miscible in all proportions with *alcohol* and *water*. It affords the reactions characteristic of ferric salts and of sulphates. It should yield no characteristic reaction with the tests for ferrous salts. Specific gravity 1·441. 5 cubic centimetres diluted with 80 cubic centimetres of *water* should give, upon the addition of an excess of *solution of ammonia*, a precipitate which, when well washed and incinerated, weighs 1·04 grammes." Prof. Procter found that a preparation containing 120 grains of sesquioxide to the fluidounce is apt to deposit the anhydrous sulphate on standing. This solution, though powerfully astringent, is too irritant for general use. The chief employment of it is in making other ferruginous preparations in which the ferric hydrate is wanted; and it should always be kept on hand for the quick preparation of the antidote to arsenic.

LIQUOR HAMAMELIDIS. Br. Solution of Hamamelis.

(LĪ'QUOR HĂM-Ą-MĔL'Į-DĬS.)

"Fresh Hamamelis Leaves, 50 *ounces* (Imperial) or 1000 grammes; Water, 100 *fl. ounces* (Imp. meas.) or 2000 cubic centimetres; Alcohol (90 per cent.), 10 *fl. ounces* (Imp. meas.) or 200 cubic centimetres. Macerate in a still for twenty-four hours; then distil one-half." *Br.*

This distilled extract of witchhazel has been introduced into the Br. Ph. 1898 to satisfy the popular demand for an external application which can be used *ad libitum* without injury. (See *Aqua Hamamelidis*, National Formulary, PART II.) It represents whatever of medical virtue Hamamelis can communicate to a distillate, and may be used freely as an embrocation or internally in the dose of a teaspoonful.

LIQUOR HYDRARGYRI NITRATIS. U. S. (Br.) Solution of Mercuric Nitrate.

(LĪ'QUOR HĪ-DRĂR'ĢĮ-RĪ NĪ-TRĀ'TĬS.)

"A liquid containing about 60 per cent. of Mercuric Nitrate [$Hg(NO_3)_2 = 323{\cdot}58$], together with about 11 per cent. of free Nitric Acid." *U. S.*

Liquor Hydrargyri Nitratis Acidus, *Br.;* Acid Solution of Mercuric Nitrate; Solution of Nitrate of Mercury; Liquor Hydrargyri Nitrici Oxydati; Deutazotate (Pernitrate) de Mercure liquide, *Fr.;* Flüssiges Salpetersaures Quecksilberoxyd, *G.*

"Red Mercuric Oxide, *forty grammes* [or 1 ounce av., 180 grains]; Nitric Acid, *forty-five grammes* [or 1 ounce av., 257 grains]; Distilled Water, *fifteen grammes* [or 231 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the Nitric Acid with the Distilled Water, and dissolve the Red Mercuric Oxide in the mixture. Keep the product in glass-stoppered bottles." *U. S.*

"Mercury, 4 *ounces* (Imperial) or 120 grammes; Nitric Acid, 5 *fl. ounces* (Imp. meas.) or 150 cubic centimetres; Distilled Water, 1½ *fl. ounces* (Imp. meas.) or 45 cubic centimetres. Mix the Nitric Acid with the Distilled Water in a flask; dissolve the Mercury in the mixture without the application of heat; then boil gently for fifteen minutes; cool, and preserve the Solution, which should weigh about three times the quantity of the Mercury employed, in a stoppered bottle not exposed to the light." *Br.*

In the British process, mercury is dissolved, with the assistance of heat, in an excess of nitric acid, and there is formed an acid mercuric nitrate, which is brought to a determinate bulk by evaporation. The proportion of nitric acid is sufficient not only to form mercuric nitrate, but also to furnish a large excess of acid.

Properties. Solution of mercuric nitrate is "a clear, nearly colorless, heavy liquid, having a faint odor of nitric acid, and a strongly acid reaction. Specific gravity, about 2·100 at 15° C. (59° F.). On evaporating a few drops of the Solution in a porcelain capsule, a white residue is left, which, on being heated, becomes successively yellow, red, and brown, and is finally completely volatilized. On a bright surface of copper, the Solution deposits a coating of metallic mercury. The Solution, diluted with water, yields with potassium or sodium hydrate test-solution a yellow precipitate; and with potassium iodide test-solution a bright red one, soluble in an excess of the reagent. A clear crystal of ferrous sulphate dropped into the solution rapidly acquires a brown color, and becomes surrounded by a brownish-black zone. No

precipitation or cloudiness should occur in the Solution on the addition of water, or of diluted hydrochloric acid (absence of *mercurous salt*)." *U. S.* "A colorless and strongly acid liquid, which affords the reactions characteristic of mercuric salts and nitrates. It should not yield any characteristic reaction with the tests for mercurous salts. Specific gravity about 2·0." *Br.*

In the U. S. P. 1880 the definition stated that this solution contained about 50 per cent. of mercuric nitrate; in the *A. J. P.*, 1886, p. 577, F. X. Moerk affirms that it does not afford a 50-per-cent. solution, but a stronger one,—*i.e.*, a 60-per-cent. To make a 50-per-cent. solution the following quantities should be used: Red Mercuric Oxide 33·32 parts; Nitric Acid 37·38 parts; Distilled Water sufficient to make 100 parts.

Mercuric nitrate, the salt present in this preparation, can be obtained in large crystals of the composition $2(Hg(NO_3)_2) + H_2O$, when its solution is allowed to evaporate slowly over sulphuric acid. The same salt, which is very deliquescent, is obtained as a crystalline magma by adding strong nitric acid to the concentrated solution.

Medical Properties. This preparation is much used as a caustic application to *cancers*, *lupus*, *ulcerations* of the *cervix*, *chancres*, etc. When a very free use is desired, it may be applied to the diseased surface by a camel's-hair brush, or preferably by a brush made of spun glass; usually, however, the application is made with a glass rod, or a match or similar fragment of wood. In *acne* and *boils*, a drop proportioned in size to the pustule applied to the apex is sometimes of service. The parts touched immediately become white, the surrounding parts inflame, and in a few days a yellow scab is formed, which gradually falls off. Sometimes the application produces salivation. When it is desirable to avoid this result, the cauterized part should be washed with water immediately after the application of the caustic.

LIQUOR HYDRARGYRI PERCHLORIDI. Br. Solution of Mercuric Chloride.

(LĪ'QUOR HĬ-DRÄR'ĢĬ-RĪ PĔR-ȻHLŌ'RĮ-DĪ.)

Liquor Hydrargyri Bichloridi, *London;* Solution of Bichloride of Mercury.

"Mercuric Chloride, 10 *grains* (Imperial) or 1 gramme; Distilled Water 1 *pint* (Imp. meas.) or 875 cubic centimetres. Dissolve. This Solution contains $\frac{1}{16}$ grain of Mercuric Chloride in 1 fluid drachm, or 0·114 gramme in 100 cubic centimetres." *Br.*

This solution may be used as affording a convenient method of exhibiting corrosive sublimate. The ammonium chloride formerly used (Br. Ph. 1885) to aid in dissolving the mercuric chloride has been omitted in the process of the Br. Ph. 1898. The dose is from half a fluidrachm to two fluidrachms (1·9–7·5 C.c.).

LIQUOR IODI COMPOSITUS. U. S. (Br.) Compound Solution of Iodine.

[Lugol's Solution.]

(LĪ'QUOR Ī-Ō'DĪ CǪM-PŌŞ'Į-TŬS.)

Liquor Iodi Fortis, *Br.*, Strong Solution of Iodine; Liniment of Iodine, *Br.* 1885; Liquor Iodinii Compositus, *U. S.* 1870; Solution of Iodine; Soluté ioduré de Lugol, *Fr.;* Lugol'sche Jodlösung, *G.*

"Iodine, *five grammes* [or 77 grains]; Potassium Iodide, *ten grammes* [or 154 grains]; Distilled Water, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Iodine and Potassium Iodide in a sufficient quantity of Distilled Water to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]. Keep the Solution in glass-stoppered bottles." *U. S.*

"Iodine, 1¼ *ounces* (Imperial) or 50 grammes; Potassium Iodide, ¾ *ounce* (Imp.) or 30 grammes; Distilled Water, 1¼ *fl. ounces* (Imp. meas.) or 50 cubic centimetres; Alcohol (90 per cent.), 9 *fl. ounces* (Imp. meas.) or 360 cubic centimetres. Dissolve the Potassium Iodide and the Iodine in the Distilled Water in a bottle; add the Alcohol and shake." *Br.*

In this solution iodine is dissolved in water with the assistance of potassium iodide. Iodine dissolves sparingly in water, but freely in a solution of this salt. In using potassium iodide to render iodine more soluble in water, the iodide is generally taken in a quantity twice the weight of the iodine; and this is the proportion adopted in the U. S. formula. The preparation is a *concentrated* solution of iodine with potassium iodide, and is intended to facilitate the administration of the combination in drops. The present formula does not differ in strength from that of 1880. The specific gravity of the U. S. compound solution of iodine is 1·124. In the Br. Pharmacopœia a solution is directed having much more iodine than the U. S. solution, and weaker in potassium iodide; the former having about fifty grains of iodine and thirty grains of potassium iodide in the fluidounce, whilst the latter has nearly twenty-six grains of

iodine and fifty-two grains of potassium iodide in the fluidounce, the difference in the fluidounce of the two Pharmacopœias being too small to enter into the calculation. The British solution is made with alcohol, and closely resembles the *Liniment of Iodine* of the Br. Ph. 1885. "If 12·66 Gm. of the Solution be mixed with a few drops of starch test-solution, it should require, for complete decoloration, from 49·3 to 50 C.c. of sodium hyposulphite decinormal volumetric solution (each C.c. of the volumetric solution corresponding to 0·1 per cent. of iodine)." *U. S.* The medicinal properties of the solution depend mainly on the free iodine contained in it. The dose of the U. S. P. solution is five minims (0·3 C.c.), containing about a quarter of a grain of iodine, three times a day, given in at least four tablespoonfuls of water or of milk, so as to avoid irritation of the stomach. The British solution, although not intended for internal administration, might be given in doses of two minims (0·12 C.c.).

LIQUOR KRAMERIÆ CONCENTRATUS. Br. Concentrated Solution of Krameria.

(LĪ'QUOR KRĄ-MĒ'RI-Æ CŎN-CĔN-TRĀ'TŬS.)

"Krameria Root, in No. 40 powder, 10 *ounces* (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 *fl. ounces* (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Krameria with *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This concentrated solution of the Br. Ph. 1898 is really a 50 per cent. fluid extract, or a half strength official fluid extract. It belongs to the class of "liquors" introduced for the purpose of diluting with water to make infusions. (See *Infusum Krameriæ*, p. 734.) This preparation fully represents the crude drug, and may be used internally in dose of from one-half to one fluidrachm (1·9–3·7 C.c.).

LIQUOR MAGNESII CARBONATIS. Br. Solution of Magnesium Carbonate. [Fluid Magnesia.]

(LĪ'QUOR MĂG-NĒ'ŞI-Ī CĂR-BO-NĀ'TĪS.)

Eau magnésienne, Magnésie liquide, *Fr.;* **Kohlensaure Magnesialösung,** *G.*

"Magnesium Sulphate, 2 *ounces* (Imperial) or 40 grammes; Sodium Carbonate, 2½ *ounces* (Imp.) or 50 grammes; Distilled Water, *a sufficient quantity.* Dissolve the two salts separately, each in *half a pint* (Imp. meas.) or two hundred cubic centimetres of the Distilled Water; heat the solution of Magnesium Sulphate to the boiling point; add to it the solution of Sodium Carbonate; boil them together until carbonic anhydride ceases to be evolved; collect the precipitated magnesium carbonate on a calico filter; wash it with Distilled Water until the filtrate is free from sulphate. Mix the washed precipitate with *a pint* (Imp. meas.) or four hundred cubic centimetres of Distilled Water; place the mixture in a suitable apparatus; force into it pure washed carbonic anhydride; let the mixture remain in contact with excess of carbonic anhydride, retained under a pressure of about three atmospheres, for twenty-four hours or longer; decant the Solution, into which again pass carbonic anhydride. Keep the Solution in bottles of convenient sizes, securely closed to prevent the escape of carbonic anhydride." *Br.*

The object of this process is to obtain a solution of magnesium carbonate by means of carbonic acid, the carbonate being insoluble in pure water. The first step is to prepare a freshly precipitated hydrated magnesium carbonate, which is more readily dissolved than is a carbonate which has been kept for some time. As the magnesium carbonate of the Br. Pharmacopœia consists of three mols. of the neutral carbonate and one of magnesium hydrate with four mols. of water, it follows that, in its preparation from the two salts used in the process, a portion of carbonic acid escapes; and the boiling is directed to be continued until the escape of the gas ceases, so that the normal composition may be insured, and a longer heat, which might affect the constitution of the carbonate so as to diminish its solubility, avoided. The precipitate is thoroughly washed, in order to remove every trace of sodium sulphate, which may be indicated by the non-action of the test of barium chloride. The next step is to dissolve the precipitated carbonate in water impregnated with carbonic acid gas; and, as the solution even thus favored is slowly effected, the carbonate is directed to remain exposed to the action of carbonic acid gas, under pressure, for twenty-four hours; and still the whole of the carbonate is not dissolved,

and filtration is necessary. According to the Br. Pharm. the solution "Effervesces slightly, or not at all, when the containing vessel is first opened. It should yield no characteristic reaction with the test for sulphates. 20 cubic centimetres evaporated to dryness afford a white residue of pure hydrous magnesium carbonate, which after being calcined weighs between 0·16 and 0·19 gramme. This residue is insoluble in *water*, and when dissolved in dilute acid responds to the tests for magnesium. This Solution contains nearly 10 grains of the official Magnesium Carbonate in 1 fluid ounce, or about 2 grammes in 100 cubic centimetres." On exposure to the air, some of the carbonic acid escapes, and a portion of the salt is deposited. Prof. Redwood proposes to remedy this by reducing the strength of the solution. (*P. J. Tr.*, 2d ser., xi. 397.) Indeed, it has been shown by Mr. C. Muncy that the preparation as it occurs in commerce is usually much below the standard strength.

This solution is but slightly effervescent, is clear, and should be free from bitterness. Nevertheless its taste is more disagreeable than is that of the undissolved carbonate, over which it has no advantage. The dose as an antacid laxative is from one to two fluidounces (30–60 C.c.).

LIQUOR MAGNESII CITRATIS. U. S. Solution of Magnesium Citrate.

(LĪ'QUOR MĂG-NĒ'ŞI-Ī CĪ-TRĀ'TĪS.)

Solution of Citrate of Magnesium; Limonade au Citrate de Magnésie, *Fr.*; Flüssige Citronensaure Magnesia, *G.*

"Magnesium Carbonate, *fifteen grammes* [or 231 grains]; Citric Acid, *thirty grammes* [or 462 grains]; Syrup of Citric Acid, *sixty cubic centimeters** [or 2 fluidounces, 14 minims]; Potassium Bicarbonate, *two and one-half grammes* [or 39 grains]; Water, *a sufficient quantity*. Dissolve the Citric Acid in *one hundred and twenty cubic centimeters* [or 4 fluidounces, 28 minims] of Water, and, having added the Magnesium Carbonate, stir, until it is dissolved. Filter the solution into a strong bottle of the capacity of about *three hundred and sixty cubic centimeters* [or 12 fluidounces, 84 minims], containing the Syrup of Citric Acid. Then add enough Water to nearly fill the bottle, drop in the Potassium Bicarbonate, immediately close the bottle with a cork, and secure it with twine. Lastly, shake the mixture occasionally, until the Potassium Bicarbonate is dissolved." *U. S.*

This formula first appeared in the second edition of the U. S. Pharmacopœia of 1850. The original formula was soon found to have defects. Four-fifths of the carbonate were dissolved in the citric acid, and the solution filtered into a bottle containing the syrup of citric acid; and then the reserved fifth, mixed with water, was added to the acid citrate, and the bottle tightly corked. The addition of the reserved carbonate was intended to impregnate the preparation with carbonic acid by its solution in the excess of citric acid. To effect the solution of this reserved carbonate required at least half an hour. But the chief objection to the formula as originally framed was that the magnesium citrate, when the solution was kept for some days, crystallized out in the form of a white granular precipitate, which rendered the solution unfit for medical use. This precipitate was found by Prof. Procter to be $Mg_3(C_6H_5O_7)_2 + 14H_2O$. This still occurs to some extent, although more slowly, and probably cannot be avoided except by a very great reduction in the amount of magnesia.† The use of potassium bicarbonate introduces potassium citrate, but in too small a proportion to be of any consequence. It is somewhat more convenient to use calcined magnesia in place of the carbonate, and in one of the best processes that we have seen the fifteen grammes of carbonate in the official formula are replaced by five grammes of Jennings's light calcined magnesia. We prefer a modification in the manipulation of the official process: if instead of the solution being filtered into the bottles containing the syrup it is filtered into a separate vessel, and then the proper quantity poured very carefully down the inside of the bottle, so as not to disturb the heavy layer of

* In the earlier issues of the U. S. P. 1890 this quantity is given as 120 C.c. This is an error, 60 C.c. being intended, which makes the solution sweet enough.

† *Extemporaneous Liquor Magnesii Citratis.* The following formula has been proposed by Mr. J. C. Wharton as a means of always giving a customer a fresh solution of the citrate, which is substantially the same as that of the U. S. Pharmacopœia. "Syrup No. 1. Take of simple Syrup two pints; Spirit of Lemon sixty-four minims; Potassium Bicarbonate six hundred and forty grains. Mix, and make solution, and keep ready for use. Syrup No. 2. Take of Calcined Magnesia eighty-eight grains; Citric Acid four hundred and eight grains: Distilled Water a sufficient quantity. Mix the Magnesia and Citric Acid in a mortar and add one and a half fluidounces of Water. Stir with a pestle, and break up the lumps of acid if there be any. After solution is effected, add sufficient Water to make up the amount of one bottle nearly full, when mixed with two fluidounces of Syrup No. 1. These two solutions are to be kept separately. When Solution of Magnesium Citrate is called for, pour into the bottle Syrup No. 1 first, without touching the mouth or sides of the bottle; then pour in along the sides of the bottle Syrup No. 2, so as to avoid as far as possible mixing them, cork and agitate." For Edel's process, see *Proc. A. P. A.*, 1894, 582; Widlum's process, *Proc. A. P. A.*, 1896, 428.

syrup, and then the crystals of bicarbonate dropped in, very little loss of carbonic acid will ensue if the bottle is at once securely corked. When the bottle is dispensed, a vigorous shake at once liberates the carbonic acid, and the patient is sure to have a highly effervescent liquid.

Properties. This official solution is founded on a preparation proposed by M. Roge Delabarre, and improved by M. Rabourdin, of Paris. It is an aqueous solution of magnesium citrate, containing an excess of citric acid, impregnated with carbonic acid and sweetened with syrup. When properly prepared, it is a clear liquid, having an agreeable taste like that of lemonade. Overlooking the excess of acid which it contains, the salt present is the tribasic citrate, in which the six atoms of hydrogen of two mols. of citric acid are replaced by three atoms of magnesium. Accordingly, it consists of two mols. of citric acid and three atoms of magnesium. It is advisable in preparing the solution to introduce the magnesia by small portions, as if too hastily added it is liable to the formation of the neutral citrate, which cannot afterwards be readily dissolved. (*A. J. P.*, 1867.) Dorvault makes a solid magnesium citrate which is perfectly and readily soluble, by melting on a sand-bath 100 parts of crystallized citric acid in its water of crystallization, and thoroughly incorporating with it 29 parts of calcined magnesia. A pasty mixture is formed, which soon hardens, and may be pulverized for use. Magnesium citrate, thus prepared, is soluble in twice its weight of water. When in saturated solution it soon precipitates as a nearly insoluble hydrate; but with eight or ten times its weight of water it forms a permanent solution. See the report on the solid citrate, made by E. Parrish and A. Smith, to the Philadelphia College of Pharmacy. (*A. J. P.*, 1852.) See, also, M. E. Robiquet's paper on lemonades of magnesium citrate (*Journ. de Pharm.*, Avril, 1852), and his formula for preparing a soluble magnesium citrate. (*A. J. P.*, July, 1855.) M. Simonin finds that an insoluble magnesium citrate may be restored to solubility in boiling water by being thoroughly rubbed up with water so as to form a paste. The necessary trituration will be abridged if a little citric acid be added. (*Ann. de Thérap.*, 1857.)* For other modifications, suggestions, etc., see Kondratowisch, *N. R.*, 1883, p. 246; Neynaber, *A. J. P.*, 1884, p. 472 (the proposed substitution of acetic acid by the latter is not desirable, because of the impossibility of avoiding an empyreumatic taste); also C. B. Stevens, *Proc. Mich. State Pharm. Assoc.*, 1885, and F. W. Sennewald, *Nat. Drug.*, 1887.

Magnesium metatartrate has been proposed, in the place of the citrate, by M. Léger, who, however, states that as a purgative it is more powerful than the citrate, resembling the sulphate. On account of its pleasant taste it might, perhaps, be substituted for Epsom salt. M. Léger prepares *metatartaric acid* in the following manner. Into a porcelain capsule put a small amount of tartaric acid, and heat it, with occasional agitation, on a slow fire until it fuses; then add successively small portions of the acid, so as not to cool the mass, lest it solidify and burn. When the capsule is two-thirds full, cease putting more in, but continue the heat until the mass, at first puffed up and doughy, is completely melted into an amber-colored liquid. Withdraw from the fire, and when sufficiently cooled form into pebbles, which must be kept in closely-stopped bottles on account of their being hygroscopic. This acid is very soluble in water, and in this state greedily attacks the magnesium carbonate, forming with it a salt which is permanent even when in solution. (*Journ. de Pharm.*, xix. 226.)

Medical Properties. This solution is a cooling cathartic, and operates mildly. It has come into extensive use in the United States, on account of the facility with which it may be

* *Solid Magnesium Citrate.* This salt as heretofore prepared, though soluble at first, is apt to become more or less insoluble when kept, in consequence of molecular change. The following process, by M. de Letter, of Brussels, yields a salt which is said to retain its solubility indefinitely. "Take of Citric Acid 20 parts, and of Magnesium Carbonate 12 parts. Powder the acid finely, and mix it intimately with the carbonate, also in fine powder. Allow the mixture to stand, at the ordinary temperature, for four or five days, or until it ceases to manifest reaction, when a little is thrown into water. During this time the powder slowly swells up, and gradually assumes the appearance of a spongy mass. Dry this at 30° C. (86° F.), pulverize it, and keep the powder in closely-stopped vials." According to M. de Letter, water, in a certain quantity, favors the formation of an insoluble hydrate; and hence the success of his process, in which no other water is present than that which is solidified in the dry materials. (*A. J. P.*, 1863, p. 312.) M. Hager has been unable to prepare a soluble salt by the process of M. de Letter. He considers magnesium citrate as presenting itself in three forms: 1, *crystallizable*, soluble in from 80 to 90 parts of water, with the formula $Mg_3(C_6H_5O_7)_2 + 7H_2O$; 2, *amorphous*, soluble in 2 parts of water; and, 3, *metamorphous*, soluble in 8 or 10 parts of water, with a strong tendency to crystallize. It is the crystalline variety, presenting the form of microscopic needles, that occasions the difficulty; and its production should be avoided. M. Hager proceeds in the following manner. Rub 40 parts of citric acid and 25 of magnesium carbonate, both in powder, with sufficient alcohol of ·833 to make a thick mixture; and, having allowed this to stand for several days, at a medium temperature, dry it at a heat of 45° C. (113° F.). The product is the amorphous salt, soluble in 2·5 parts of water, in half an hour at 155° C. (60° F.), immediately at 30° C. (86° F.). Its solution, whether made with hot or with cold water, retains its clearness after long standing. The salt is neutral, and contains about 13 mols. of water. To succeed certainly it is necessary that the magnesium carbonate be free from dust and impurities. (*Ibid.*, 1864, p. 19.)

taken, and its acceptability to the stomach. The dose as a full purge is the whole quantity directed in the formula, or twelve fluidounces (360 C.c.); as a laxative, half that quantity.

LIQUOR MORPHINÆ ACETATIS. Br. Solution of Morphine Acetate.

(LĪ'QUOR MÖR-PHĪ'NÆ ĂÇ-Ę-TĀ'TĬS.)

Soluté d'Acétate de Morphine, *Fr.;* Essigsaure Morphinlösung, *G.*

"Morphine Acetate, 17½ *grains* (Imperial) or 1 gramme; Diluted Acetic Acid, 38 *minims* (Imp. meas.) or 2 cubic centimetres; Alcohol (90 per cent.), 1 *fl. ounce* (Imp. meas.) or 25 cubic centimetres; Distilled Water, *a sufficient quantity.* Mix the Alcohol with an equal volume of Distilled Water, adding the Diluted Acetic Acid; dissolve the Morphine Acetate in the mixture; dilute with sufficient Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution of Morphine Acetate. 110 minims contain 1 grain of Morphine Acetate; 100 cubic centimetres contain 1 gramme." *Br.*

Morphine Acetate often contains a little uncombined morphine, in consequence of the escape of a portion of the acid during its evaporation, and especially when this is pushed to dryness. It is on this account apt to be unreliable. Hence the addition of the diluted acetic acid, which at the same time neutralizes the alkaloid in excess and enables the solution to be completely effected. The spirit is added as a preservative. The present solution contains now 1 per cent. of morphine acetate. The dose is from fifteen to thirty minims (0·9–1·9 C.c.), equivalent to from one-eighth to one-quarter of a grain of the acetate, and to about as many drops of laudanum as minims of the solution.

LIQUOR MORPHINÆ HYDROCHLORIDI. Br. Solution of Morphine Hydrochloride.

(LĪ'QUOR MÖR-PHĪ'NÆ HĬ-DRO-ÇHLŌ'RĮ-DĪ.)

Solution of Hydrochlorate of Morphine, *Br.* 1885; Liquor Morphiæ Muriatis, *Dub.;* Solution of Muriate of Morphia; Soluté de Hydrochlorate de Morphine, *Fr.;* Salzsaure Morphinlösung, *G.*

"Morphine Hydrochloride, 17½ *grains* (Imperial) or 1 gramme; Diluted Hydrochloric Acid, 38 *minims* (Imp. meas.) or 2 cubic centimetres; Alcohol (90 per cent.), 1 *fl. ounce* (Imp. meas.) or 25 cubic centimetres; Distilled Water, *a sufficient quantity.* Mix the Alcohol with an equal volume of Distilled Water, adding the Diluted Hydrochloric Acid; dissolve the Morphine Hydrochloride in the mixture; dilute with sufficient Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution of Morphine Hydrochloride. 110 minims contain 1 grain of Morphine Hydrochloride; 100 cubic centimetres contain 1 gramme." *Br.*

The use of the alcohol is to prevent spontaneous decomposition, that of the acid probably to assist in the solution of the salt. The dose of the British solution for an adult is from fifteen to thirty minims (0·9–1·9 C.c.) or drops, containing from an eighth to a quarter of a grain of the hydrochlorate, and about equivalent to as many drops of laudanum. The solution contains now 1 per cent. of morphine hydrochloride.

LIQUOR MORPHINÆ TARTRATIS. Br. Solution of Morphine Tartrate.

(LĪ'QUOR MÖR-PHĪ'NÆ TĂR-TRĀ'TĬS.)

"Morphine Tartrate, 17½ *grains* (Imperial) or 1 gramme; Alcohol (90 per cent.), 1 *fl. ounce* (Imp. meas.) or 25 cubic centimetres; Distilled Water, *a sufficient quantity.* Mix the Alcohol with an equal volume of Distilled Water; dissolve the Morphine Tartrate in the mixture; add sufficient Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution.

This solution was introduced into the Br. Ph. 1898 because of the superior solubility and stability of the morphine tartrate, and its adaptability for hypodermic administration, alcohol being used to preserve the liquid. It is of the same strength as the other solutions of morphine,—*i.e.*, 1 per cent. "110 minims contain 1 grain of Morphine Tartrate; 100 cubic centimetres contain 1 gramme." *Br.* The dose is from fifteen to thirty minims (0·9–1·9 C.c.).*

* Various solutions of morphine sulphate have been in vogue, but have been abandoned by the Pharmacopœias on account of their tendency to undergo decomposition. The U. S. 1870 solution contained 1 grain of morphine sulphate to the fluidounce; the Br. 1885 solution 4·375 grains in the same quantity. *Magendie's solution* was of the strength of 16 grains to the fluidounce.

LIQUOR PANCREATIS. Br. Pancreatic Solution.

(LĪ'QUOR PĂN-CRĒ'Ą-TĪS.)

"A liquid preparation containing the digestive principles of the fresh pancreas of the pig. The preparation is most active when the animal from which it is obtained has been fed shortly before being killed. *Five ounces* (Imperial) or two hundred and fifty grammes of the pancreas, freed from fat and external membrane and finely divided by trituration with washed sand or powdered pumice stone, should be digested, in a closed vessel, in *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of Alcohol (20 per cent.) for seven days, and then filtered." *Br.*

This new official of the Br. Ph. 1898 has been introduced to supply the demand for a liquid digestive solution made from the pancreas; it closely resembles the preparation recommended by Benger. (*Proc. Roy. Soc.*, xxxii. 145; see also *Pancreatinum.*) The test, modelled on the U. S. P. test for pancreatin, is as follows: "If 2 cubic centimetres of the Solution, together with 0·2 gramme of *sodium bicarbonate* and 20 cubic centimetres of *water*, be added to 80 cubic centimetres of milk, and the mixture be kept at a temperature of 113° F. (45° C.) for one hour, coagulation should no longer occur on the addition of *nitric acid*." *Br.* The solution digests albuminoids, converts starch into sugar in an alkaline solution, albumen and fibrin into peptones, and peptonizes milk. As it acts normally in alkaline solutions, whilst the gastric juices are strongly acid, its practical value as an internal medicament is doubtful. The dose is from one to two fluidrachms (3·7–7·3 C.c.).

LIQUOR PICIS CARBONIS. Br. Solution of Coal Tar.

(LĪ'QUOR PĪ'CĬS CĂR-BŌ'NĬS.)

"Prepared Coal Tar, 4 *ounces* (Imperial) or 200 grammes; Quillaia Bark, in No. 20 powder, 2 *ounces* (Imp.) or 100 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Moisten the powdered Quillaia Bark with *one fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process with the remainder of the Alcohol as for Tinctures, *one pint* (Imp. meas.) or one thousand cubic centimetres being produced. To the resulting percolate add the Prepared Coal Tar, and digest the mixture at 120° F. (48·9° C.) for two days, occasionally stirring. Cool and decant, or filter." *Br.*

This solution of the Br. Ph. 1898 is practically identical with *Liquor Carbonis Detergens*, *Coal Tar Saponine*, and similar well-known preparations which have been largely used by dermatologists. The process for solution of coal tar is modelled after that for *compound tincture of coal tar*, proposed by Dr. L. A. Duhring (*Amer. Journ. Med. Sciences*), who recommended digesting 1 part of coal tar with 6 parts of tincture of quillaja for eight days, and then filtering. It owes its virtues largely to phenol and other derivatives of coal tar. (See *Coal Tar*, PART II.)

Solution of coal tar is stimulating, and is prescribed, diluted with from ten to fifty parts of water, as a wash in *eczema*, *psoriasis*, *pruritus*, and other skin diseases.

LIQUOR PLUMBI SUBACETATIS. U. S. (Br.) Solution of Lead Subacetate.

(LĪ'QUOR PLŬM'BĪ SŬB-ĂÇ-Ē-TĀ'TĪS.)

"An aqueous liquid, containing in solution about 25 per cent. of Lead Subacetate [approximately $Pb_2O(C_2H_3O_2)_2 = 546{\cdot}48$]." *U. S.*

Liquor Plumbi Subacetatis Fortis, *Br.*, Strong Solution of Lead Subacetate, Goulard's Extract; Liquor Plumbi Subacetici, *P. G.*; Acetum Plumbicum, Acetum Saturni, Plumbum Hydrico-Aceticum Solutum; Sous-acétate de Plomb liquide, Extrait de Goulard, Vinaigre de Plomb (de Saturne), *Fr.*; Bleiessig, *G.*

"Lead Acetate, *one hundred and seventy grammes* [or 6 ounces av.]; Lead Oxide, *one hundred grammes* [or 3 ounces av., 231 grains]; Distilled Water, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the Lead Acetate in *eight hundred grammes* [or 28 ounces av., 96 grains] of boiling Distilled Water, in a glass or porcelain vessel. Then add the Lead Oxide, previously passed through a fine sieve, and boil for half an hour, occasionally adding hot Distilled Water to make up the loss by evaporation. Remove the heat, allow the liquid to cool, and add enough Distilled Water, previously boiled and cooled, to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Finally, filter the liquid in a closely covered funnel. Keep the product in well-stoppered bottles." *U. S.*

"Lead Acetate, 5 *ounces* (Imperial) or 250 grammes; Lead Oxide, in powder, 3½ *ounces* (Imp.) or 175 grammes; Distilled Water, *a sufficient quantity*. Boil the Lead Acetate and the Lead Oxide in *one pint* (Imp. meas.) or one thousand cubic centimetres of Distilled Water for half an hour, constantly stirring, and maintaining the volume of the liquid by occasional additions of Distilled Water; filter; when the liquid is cold add sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Strong Solution." *Br.* The sp. gr. of the solution is 1·275.

The U. S. 1890 process does not differ essentially from that formerly official. Crystallized lead acetate consists of one atom of lead 206·5, two acetic acid groups 118, and three molecules of water 54 = 378·5. The formula is $Pb(C_2H_3O_2)_2 + 3H_2O$. Litharge, as usually found in commerce, is an impure lead oxide. When the solution of the former is boiled with the latter, a large quantity of the oxide is dissolved, and a lead subacetate is formed which remains in solution. The precise composition of the subacetate varies with the proportion of lead acetate and of litharge employed. Thus, starting with three molecules of normal acetate, $Pb_3(C_2H_3O_2)_6$, we may have $Pb_3O(C_2H_3O_2)_4$ and $Pb_3O_2(C_2H_3O_2)_2$ formed successively. The latter of these oxyacetates is known as Goulard's, and a mixture of the two constitutes the basis of the official solution. In executing the process, the litharge should be employed in very fine powder, and, according to Thénard, should be previously calcined in order to decompose the lead carbonate which it always contains in greater or less proportion, and which is not dissolved by the solution of the acetate. M. Nevning states that a solution of lead subacetate more permanent than the official one may be prepared by simply allowing litharge to remain for twenty-four hours in a solution of lead acetate, with occasional agitation. This preparation probably contains much less of the lead oxide than does the official solution. Courtonne recommends dissolving seventy-five parts by weight of crystallized lead acetate in one hundred and sixty-five parts of water, and adding eleven parts of ammonia water, sp. gr. 0·923. This quick method has the disadvantage of containing ammonium acetate in small quantity. (*Chem. Zeit.*, 1894.) For Haussmann's method by agitation with hot water, see *A. J. P.*, 1897, 559; see also *A. J. P.*, 1896, 427; *Merck's Report*, 1896, 329.

Properties. The solution of lead subacetate of the Pharmacopœias is "a clear, colorless liquid, odorless, having a sweetish, astringent taste, and an alkaline reaction. On exposure to the air it absorbs carbon dioxide, which causes the formation of a white precipitate. Specific gravity, about 1·195 at 15° C. (59° F.). When Solution of Lead Subacetate is added to a solution of acacia, it produces a dense, white precipitate (distinction from an aqueous solution of *normal lead acetate*). In other respects the Solution conforms to the reactions and tests given under Lead Acetate (see *Plumbi Acetas*). If 13·67 Gm. of the Solution be diluted with 50 C.c. of water, there will be required, for complete precipitation of the lead, about 25 C.c. of normal sulphuric acid (each C.c. corresponding to 1 per cent. of Lead Subacetate), methyl-orange being used as indicator." *U. S.* "A clear colorless liquid, with alkaline reaction and sweet astringent taste. It becomes turbid by exposure to the air. It forms with *mucilage of gum acacia* an opaque white jelly. It affords the reactions characteristic of lead and of acetates. Specific gravity 1·275. Each gramme should require for complete precipitation 17 cubic centimetres of the *decinormal volumetric solution of sulphuric acid*." *Br.* When concentrated by evaporation, it deposits on cooling crystalline plates, which, according to Dr. Barker, are flat, rhomboidal prisms, with dihedral summits.* It has an alkaline reaction, tingeing the syrup of violets green, and reddening turmeric paper. One of its most striking properties is the extreme facility with which it is decomposed. Carbonic acid throws down a white precipitate of lead carbonate; and this happens by mere exposure to the air, or by mixture even with distilled water, if this has had an opportunity of absorbing carbonic acid from the atmosphere. It affords precipitates also with the alkalies, alkaline earths, and their carbonates, with sulphuric and hydrochloric acids free or combined, with hydrogen sulphide and the sulphydrates, with the soluble iodides and chlorides, and, according to Thénard, with solutions of all the neutral salts. Solutions of gum, tannin, most vegetable coloring principles, and many animal substances, particularly albumen, produce with it precipitates consisting of the substance added and lead oxide. It should be kept in well-stopped bottles. It is known to con-

* *Crystallized Lead Subacetate.* M. Jeannel prepares crystallized lead subacetate in accordance with the following formula. Triturate six parts of neutral lead acetate with two parts of pure litharge, and add one part of water. Heat in a porcelain capsule, stirring with a glass rod, until fusion and finally ebullition occur. After two or three minutes of boiling, filter through paper in a funnel heated by a sand-bath. Allow to cool and crystallize. (*Journ. de Pharm.*, 4e sér., xi. 54.)

tain a salt of acetic acid by emitting an acetous smell when treated with sulphuric acid, and a salt of lead by yielding a white precipitate with an alkaline carbonate, a yellow one with potassium iodide, and a black one with hydrogen sulphide. It is distinguished from the solution of lead acetate by being precipitated by gum arabic. For a method of assaying this solution volumetrically, see *P. J. Tr.*, 1886, 656.

Medical Properties and Uses. This solution is astringent and sedative, but is employed only as an external application. It is highly useful in inflammation arising from *sprains*, *bruises*, *burns*, *blisters*, etc., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. From four fluidrachms to a fluidounce (15–30 C.c.), added to a pint (473 C.c.) of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker, as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action; and poisoning by its injection for gonorrhœa has been reported (*Dublin Journ. Med. Sci.*, 1874). The solution has the common name of *Goulard's extract*, derived from a surgeon of Montpellier by whom it was introduced into general notice, though previously employed.*

LIQUOR PLUMBI SUBACETATIS DILUTUS. U. S., Br. Diluted Solution of Lead Subacetate. [Lead Water.]

(LĪ'QUOR PLŪM'BĪ SŬB-ĂÇ-Ę-TĀ'TĬS DĮ-LŪ'TŬS.)

Goulard's Lotion, Goulard Water, *Br.;* Diluted Solution of Subacetate of Lead; Aqua Plumbi, *P.G.;* Eau de Saturne, Eau blanche, *Fr.;* Bleiwasser, Kühlwasser, *G.*

"Solution of Lead Subacetate, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the Solution of Lead Subacetate with enough Distilled Water, previously boiled and cooled, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Keep the Solution in well-stoppered bottles." *U. S.*

"Strong Solution of Lead Subacetate, 2 *fl. drachms* (Imperial measure) or 5 cubic centimetres; Alcohol (90 per cent.), 2 *fl. drachms* (Imp. meas.) or 5 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the Alcohol with *nineteen and a half fluid ounces* (Imp. meas.) or three hundred and ninety cubic centimetres of recently boiled and cooled Distilled Water; add the Strong Solution of Lead Subacetate and shake." *Br.*

In our comments on the U. S. process of 1850 it was stated that the strength of our official preparation, though double what it formerly was, might be still further increased with propriety. In the edition of the U. S. Pharmacopœia of 1870 the proportion was increased from two to three fluidrachms to the pint; and this proportion has been practically retained in the preparation now official. The direction to dilute the strong solution with distilled water *previously boiled and cooled* is an improvement, as even the small amount of carbonic acid dissolved in distilled water usually made the lead water cloudy. Owing to the liability to serious results due to the frequent confounding of the names lime water and lead water, it is safer to dispense lead water in a slightly opalescent condition, whilst lime water should be perfectly transparent. The Br. preparation, though stronger than the old one of the London College, is still feeble. The old French Codex directed two drachms of the strong solution to a pound of distilled water and an ounce of alcohol of 22° Baumé, and thus formed the *vegeto-mineral water* of Goulard. The minute proportion of alcohol in the British solution can have little effect. The preparation should be as much as possible excluded from the air.

LIQUOR POTASSÆ. U. S., Br. Solution of Potassa. [Solution of Potassium Hydrate.]

(LĪ'QUOR PO-TĂS'SÆ.)

"An aqueous solution of Potassium Hydrate [KOH = 55·99], containing about 5 per cent. of the hydrate." *U. S.* "An aqueous solution containing in 110 minims 6·2 grains, or in 1 fluid ounce 27 grains, of potassium hydroxide, KOH." *Br.*

Liquor Kali Caustici, *P. G.;* Kali Hydricum Solutum, Lixivium Causticum; Solution of Potash; Potasse caustique liquide, Lessive caustique, *Fr.;* Aetzkalilauge, Kalilauge, *G.*

* *Linimentum Plumbi Subacetatis*, U. S. 1880. *Liniment of Subacetate of Lead.* (*Liniment saturné, Beurre de Saturne, Baume universelle*, Fr.; *Bleiliniment*, G.) "Solution of Subacetate of Lead, *forty parts* [or two ounces av.]; Cotton Seed Oil, *sixty parts* [or three ounces av.], To make *one hundred parts* [or five ounces av.]. Mix them." *U. S.*

This preparation, which was introduced in the U. S. P. 1870, was retained in the revision of 1880, with the substitution of cotton seed oil for the olive oil, but was dropped from the revision of 1890. This liniment may be used as a sedative application in superficial inflammations.

"Potassium Bicarbonate, *eighty-five grammes* [or 3 ounces av.]; Lime, *forty grammes* [or 1 ounce av., 180 grains]; Distilled Water, *a sufficient quantity*. Dissolve the Potassium Bicarbonate in *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Distilled Water, heat the solution until effervescence ceases, and then increase the heat to the boiling point of the liquid. Slake the Lime with about *twenty cubic centimeters* [or 325 minims] of Distilled Water, then mix it well with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Distilled Water, pour the mixture into a tared flask, and, having heated it to boiling, gradually add to it the solution of Potassium Bicarbonate, and boil during ten minutes. Then add enough Distilled Water to the flask to make the contents weigh *one thousand grammes* [or 35 ounces av., 120 grains], and set the flask aside, well stoppered, until the contents are cold. Lastly, strain the liquid through linen, set it aside in a well-stoppered bottle until it has become clear by subsidence, and separate the clear solution by decantation, or by means of a siphon.

"*Solution of Potassa* may also be prepared in the following manner. Potassa, *fifty-six grammes* [or 1 ounce av., 427 grains]; Distilled Water, *nine hundred and forty-four grammes* [or 33 ounces av., 130 grains]. To make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the Potassa in the Distilled Water. The Potassa used in this process should be of the full strength directed by the Pharmacopœia (90 per cent.). Potassa of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken; the proper amount for the above formula being ascertained by dividing 5000 by the percentage of absolute Potassa (potassium hydrate) contained therein. Solution of Potassa should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum." *U. S.*

The British Pharmacopœia 1898 does not give a detailed process, merely specifying that one fluidounce shall contain twenty-seven grains of potassium hydroxide.

The object of the first U. S. Pharmacopœia process is to separate carbonic acid from the potassium carbonate or bicarbonate, so as to obtain the alkali in a caustic state. This separation of the carbonic acid is effected by calcium hydrate; and the chemical changes which take place are most intelligibly explained by supposing the occurrence of a double decomposition. The lime of the calcium hydrate, by its superior affinity, combines with the carbonic acid and precipitates as calcium carbonate, while the water of the calcium hydrate unites with the potassa and remains in solution as potassium hydrate: $K_2CO_3 + Ca(HO)_2 = 2KHO + CaCO_3$. The proportion indicated by theory for this decomposition would be 69·2 of the dry carbonate to 28 of lime, or one molecule of each; but in practice it is found necessary to use an excess of lime. The bicarbonate is preferred in the U. S. process, as affording a purer product, being itself free from the contaminations usually found in the carbonate; and the application of heat to the solution of the bicarbonate is to drive off a portion of the carbonic acid and thus bring the salt to the state of a carbonate. The proportion of water employed has a decided influence on the result. If the water be deficient in quantity, the decomposing power of the lime, on account of its sparing solubility, will be lessened, and more of it will be required to complete the decomposition of the carbonate than if the solutions were more dilute. Straining should not be used, as it causes a prolonged contact with the air, and risk of the absorption of carbonic acid, and is apt, moreover, to introduce organic matter from the strainer into the solution; it is best to allow the precipitate to subside in a closed vessel and then siphon off the clear solution. The direction to keep the solution in green glass bottles is judicious, as white flint glass is slightly acted on, and sometimes contaminates the solution with lead.

According to Prof. Wöhler, solution of pure potassium hydrate for analytical purposes may be conveniently obtained by exposing for half an hour to a moderate red heat, in a copper crucible, one part of pure nitre, and two or three parts of copper cut into small pieces. The resulting mass, consisting of potassium hydrate and black oxide of copper, is treated with water, and the solution poured into a narrow cylindrical vessel, where it is left until it gets perfectly clear by the deposition of the oxide of copper. It is then drawn off, and kept in well-stopped bottles. (*Chem. Gaz.*, Nov. 15, 1853, p. 429.) Graf and Riegel assert that potassium hydrate, thus obtained, contains potassium nitrate and nitrite, but Dr. A. Geuther found it perfectly pure, when the process was properly conducted. (*Chem. Gaz.*, June 1, 1856.) A pure hydrate may also be obtained by the process of Dr. Mohr, which consists in precipitating solution of potassium sulphate with caustic baryta, obtained from the nitrate. Thus procured, the alkali is entirely free from chlorine, silica, and sulphuric acid. (*P. J. Tr.*, xvi. 310.)

Properties. Solution of potassa is "a clear, colorless liquid, odorless, having a very acrid

and caustic taste, and a strongly alkaline reaction. Specific gravity, about 1·036 at 15° C. (59° F.). It should conform to the same reactions and tests as an aqueous solution of Potassa (see *Potassa*). To neutralize 28 Gm. of Solution of Potassa should require about 25 C.c. of normal sulphuric acid (each C.c. of the volumetric solution indicating 0·2 per cent. of absolute potassium hydrate), phenolphtalein being used as indicator." *U. S.* "A colorless, odorless, and transparent liquid having a nauseous taste. It is strongly alkaline. It should not yield any characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, calcium, magnesium, sodium, or ammonium, and should be free from more than traces of carbonates, chlorides, or sulphates. Specific gravity 1·058. 9 cubic centimetres should require for neutralization 10 cubic centimetres of the *volumetric solution of sulphuric acid*, corresponding to 0·557 gramme of potassium hydroxide, KOH, or to 6·19 grammes in 100 cubic centimetres, or to 5·85 grammes in 100 grammes. Solution of Potash should be preserved in a green glass bottle furnished with an air-tight stopper." *Br.* It acts rapidly on animal and vegetable substances, and when rubbed between the fingers produces a soapy feeling, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and forms soap with oily and fatty bodies. The U. S. solution, being obtained from potassium bicarbonate, is pure. Lead may be detected by a black precipitate produced by ammonium sulphydrate. When solution of potassa is used as a test for diabetic urine, it should be free from lead, the presence of which renders the test ambiguous. With platinic chloride it produces a yellow precipitate, showing that the alkali present is potassa. It is incompatible with acids, acidulous salts, and all metallic and earthy preparations held in solution by an acid; also with all ammoniacal salts, and with calomel and corrosive sublimate. The two official solutions of potassa vary in strength, the U. S. solution having the sp. gr. 1·036 and the Br. 1·058. These solutions are very dilute, that of the U. S. Pharm., which is the weakest, containing only 5 per cent. of potassium hydrate: the percentage of potassium hydrate in the solution of the Br. Pharm. is 5·85, or somewhat greater than in the American preparation. On account of its strong attraction for carbonic acid, solution of potassa should be carefully preserved from contact with the air. In consideration of the change to which it is liable by keeping, it may usually be advantageously prepared extemporaneously, according to the second U. S. process, by dissolving the hydrate in water.

Medical Properties and Uses. Solution of potassa is antacid, diuretic, and antilithic. It has been much employed in calculous complaints, under the impression that it has the property of dissolving urinary concretions in the kidneys and bladder; but experience has proved that the stone once formed cannot be removed by remedies internally administered; and the most that the alkaline medicines can effect is to correct that disposition to the superabundant secretion of uric acid, or the insoluble urates, upon which gravel and stone often depend. For this purpose, however, the carbonated alkalies are preferable to caustic potassa, as they are less apt to irritate the stomach and to produce injurious effects when long continued. It has been proposed to dissolve calculi by injecting immediately into the bladder the solution of potassa in a tepid state and so much diluted that it can be held in the mouth; but this mode of employing it has not been found to answer in practice. This solution has also been highly recommended in *lepra*, *psoriasis*, and other cutaneous affections, and is said to have proved peculiarly useful in *scrofula;* but in all these cases it probably acts simply by its antacid property, and is not superior to the potassium or sodium carbonate. Externally it has been used, in a diluted state, as a stimulant lotion in rachitis and arthritic swellings, and, concentrated, as an escharotic in the bite of rabid or venomous animals. The dose is from ten to thirty minims (0·6–1·9 C.c.), repeated two or three times a day, and gradually increased in cutaneous affections to from one to two fluidrachms (3·75–7·5 C.c.); but the remedy should not be too long continued, as it is apt to debilitate the stomach. It may be given in sweetened water or some mucilaginous fluid. In dyspeptic cases it may be associated with the simple bitters. In excessive doses it irritates, inflames, or corrodes the stomach. The antidotes are oils and milder acids, such as vinegar and lemon juice, which operate by neutralizing the alkali.

LIQUOR POTASSII ARSENITIS. U. S. (Br.) Solution of Potassium Arsenite. [Fowler's Solution.]

(LĪ'QUOR PO-TĂS'SI-Ī ĂR-SĒ-NĪ'TĪS.)

Liquor Arsenicalis, *Br.;* Arsenical Solution; Liquor Kali Arsenicosi, *P. G.;* Solutio Arsenicalis Fowleri, Kali Arsenicosum Solutum; Liqueur arsénicale de Fowler, *Fr.;* Fowler'sche Tropfen, *G.*

"Arsenous Acid, in fine powder, *ten grammes* [or 154 grains]; Potassium Bicarbonate, *twenty grammes* [or 309 grains]; Compound Tincture of Lavender, *thirty cubic centimeters* [or 1 fluid-

ounce, 7 minims]; Distilled Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Boil the Arsenous Acid and Potassium Bicarbonate with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Distilled Water, until solution has been effected. Then add enough Distilled Water to make the solution, when cold, measure *nine hundred and seventy cubic centimeters* [or 32 fluidounces, 384 minims], and, lastly, add the Compound Tincture of Lavender. Filter through paper." *U. S.*

"Arsenious Anhydride, in powder, 87½ *grains* (Imperial) or 10 grammes; Potassium Carbonate, 87½ *grains* (Imp.) or 10 grammes; Compound Tincture of Lavender, 5 *fl. drachms* (Imp. meas.) or 31·25 cubic centimetres; Distilled Water, *a sufficient quantity*. Heat the Arsenious Anhydride and the Potassium Carbonate with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of Distilled Water in a one-pint (or one-litre) flask until a clear solution is obtained; cool; add the Compound Tincture of Lavender and sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution." *Br.* The sp. gr. of this solution is 1·010.

This preparation originated with the late Dr. Fowler, of Stafford, England, and was intended as a substitute for the celebrated remedy known under the name of "the *tasteless ague drop*." The strength of the present official solution is somewhat greater than that of the Fowler's solution of U. S. P. 1870; it now contains 1 per cent. of arsenous acid, and the British solution has been made to correspond with this. It is a potassium arsenite dissolved in water, and is formed by the combination of the arsenous acid with the potassium of the bicarbonate or carbonate, the carbonic acid being evolved. In the present U. S. process the bicarbonate has been preferred to the carbonate, and in order to expedite the process the quantity has been doubled. As the bicarbonate is decomposed to carbonate by boiling water, there is present in the finished solution some potassium carbonate. According to M. H. Buignet, ebullition disengages the carbonic acid slowly, so that after four hours' boiling the solution still retains about one-sixth of this acid. (*Journ. de Pharm.*, 1856, p. 440.) The name by which the preparation is designated in the U. S. Pharmacopœia is the more correct. The contact of arsenous acid with potassium bicarbonate in the presence of a small quantity of boiling water gives rise to effervescence with decomposition of bicarbonate. It has, however, been denied that potassium carbonate is decomposed by arsenous acid, which is supposed to be merely held by it in solution; and, in this view of the nature of the preparation, the British name of Arsenical Solution would be appropriate. The compound spirit of lavender is added to give it taste and prevent its being mistaken for water. For Oldberg's process, see *Proc. A. P. A.*, 1893, 430; see also *A. J. P.*, 1895, 403.

In making this preparation care should be taken that the arsenous acid is pure. This object is best secured by selecting the acid in small pieces instead of the commercial powder, and powdering the lumps in a mortar. Calcium sulphate is a common impurity in the powdered acid, and if present will remain undissolved, and cause the solution to be weaker than it should be. Another insoluble impurity in the powdered acid is calcium arsenite, which is sometimes present to the amount of 25 per cent. (*Buignet.*) Hence, if the arsenous acid does not entirely dissolve, the solution must be rejected.

Properties. Solution of potassium arsenite is a transparent liquid, having slightly the color, taste, and smell of the compound spirit of lavender. It has an alkaline reaction. It is decomposed by the usual reagents for arsenic, by silver nitrate, the salts of copper, lime water, and hydrogen sulphide, and is incompatible with the infusions and decoctions of cinchona. Before hydrogen sulphide will act, the solution must be acidulated with some acid, as hydrochloric or acetic. "If 24·7 C.c. of the Solution be boiled for a few minutes with 2 Gm. of sodium bicarbonate, and the liquor, when cold, diluted with water to 100 C.c., and mixed with a little starch test-solution, it should require from 49·4 to 50 C.c. of iodine decinormal volumetric solution to produce the blue tint of starch iodide (corresponding to 1 Gm. of arsenous acid in 100 C.c. of the Solution)." *U. S.* "A reddish liquid, alkaline to *test-papers*, and having the odor of lavender. 25 cubic centimetres, neutralized with *hydrochloric acid*, and diluted with *water*, should discharge the color of 50·8 to 50·9 cubic centimetres of the *volumetric solution of iodine*, the presence of a slight excess of *sodium bicarbonate* being maintained throughout the operation. 110 minims contain 1 grain of Arsenious Anhydride; 100 cubic centimetres contain 1 gramme." *Br.* According to Dr. R. Fresenius, solutions of alkaline arsenites slowly absorb oxygen from the air, and are in part converted into arsenates. Hence the propriety of keeping this solution in small bottles well filled. Mohr states that the alkaline reaction of the official solution delays the change, and experience has confirmed this state-

ment. The slight precipitate found in this solution after keeping proved to be silicic acid, caused by the action of the alkaline solution on the glass container.

Medical Properties and Uses. This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arsenous Acid.* Its liquid form makes it convenient for exhibition and gradual increase; and it is the preparation generally resorted to when arsenic is given internally. It has been much employed in *intermittent fever.* In *chorea* it is almost a specific, and in *nervous diseases* of debility it is often very useful. In *malarial affections* and *chorea* it should be administered in ascending doses until the puffiness about the eyes or disturbance of the bowels betrays the arsenical impression. Fowler's solution is a very valuable remedy in various *skin diseases*, and has the great advantage over the solid preparations that the dose may be readily increased from day to day. One hundred minims of the solution contain very nearly one grain of arsenous acid. The average dose for an adult is five drops (0·3 C.c.) two or three times a day. For the peculiar effects upon the human organism, see *Acidum Arsenosum.*

Duflos's antidote to the poisonous effects of Fowler's solution, and of the salts of the acids of arsenic generally, is ferric acetate with excess of base, made by dissolving freshly precipitated ferric hydrate in acetic acid to saturation, adding an equal quantity of the hydrate to the solution, and diluting the whole with water to the consistence of cream. If the official solution of ferric acetate be used in an emergency, the free acid should first be neutralized with a little ammonia.

LIQUOR POTASSII CITRATIS. U.S. Solution of Potassium Citrate.

[Mistura Potassii Citratis.]

(LĪ'QUOR PO-TĂS'SI-Ī CĪ-TRĀ'TĬS.)

"An aqueous liquid, containing in solution about 9 per cent. of anhydrous Potassium Citrate [$K_3C_6H_5O_7 = 305{\cdot}63$], together with small amounts of citric and carbonic acids." *U. S.*

Liquor Kali Citrici; Citrate de Potasse liquide, *Fr.*; Flüssiges Citronensaures Kali, *G.*

"Potassium Bicarbonate, *eight grammes* [or 123 grains]; Citric Acid *six grammes* [or 92 grains]; Water, *a sufficient quantity.* Dissolve the Potassium Bicarbonate and the Citric Acid, each, in *forty cubic centimeters* [or 1 fluidounce, 169 minims] of Water. Filter the solutions separately, and wash the filters with enough Water to obtain, in each case, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]. Finally, mix the two solutions, and, when effervescence has nearly ceased, transfer the liquid to a bottle. This preparation should be freshly made, when wanted." *U. S.*

Solution of Potassium Citrate has been made identical with the mixture formerly official as *Mistura Potassii Citratis;* nevertheless, the mixture made with lemon juice will continue to be preferred by some practitioners: its formula is therefore retained here as a foot-note.* The *official*

* *Mistura Potassii Citratis.* U.S. 1880. *Mixture of Citrate of Potassium.* [*Neutral Mixture.*] (*Mistura Neutralis; Potion gazeuse (effervescente)*, Fr.) "Fresh Lemon Juice, strained, *one hundred parts* [or four fluidounces]; Bicarbonate of Potassium, about *ten parts*, or, *a sufficient quantity.* Add the Bicarbonate of Potassium gradually to the Lemon Juice until it is neutralized. This preparation should be freshly made, when wanted for use." *U. S.*

In this preparation the potassium of the bicarbonate unites with the citric acid of the lemon juice, and carbonic acid is liberated. The result, therefore, is a solution of potassium citrate in water impregnated with carbonic acid, with the flavor from the lemon juice. The solution has a greenish-yellow color, and it is not usually dispensed in a perfectly transparent condition, owing to the difficulty of filtering out the very fine albuminous precipitate found in lemon juice. About 48 grains of the crystals of the bicarbonate, 33 grains of the pure and perfectly dry carbonate, or 45 grains of the hydrated carbonate found in commerce, are sufficient to saturate a fluidounce of good lemon juice; but the strength of the juice is variable, and the carbonate is apt to absorb moisture from the air, so that precision as to quantities cannot be readily attained. Hence the propriety of the direction, in the process for the neutral mixture, to add the alkaline carbonate to saturation. The point of saturation may be determined by the cessation of effervescence, by the absence of either an acid or an alkaline taste, and still more accurately by litmus paper, which should not be rendered bright red by the solution, or blue if previously reddened by an acid. The inequality of strength in the lemon juice renders the neutral mixture prepared with it more or less uncertain; though, if the apothecary select ripe and sound fruit, and express the juice himself, the preparation will be found to approach sufficiently near a uniform standard for all practical purposes. Nevertheless, if the physician wish absolute precision, he may order the neutral mixture to be made with crystallized citric acid, as directed in Liquor Potassii Citratis; or he may pursue the following plan, suggested in former editions of this work. Dissolve two drachms of potassium bicarbonate in two fluidounces of water; saturate the solution with good fresh lemon juice, and strain; and, lastly, add enough water to make the mixture measure six fluidounces. A fluidounce is the dose of this solution.

Effervescing Draught. Under this name, potassium citrate is often prepared extemporaneously, and given in the state of effervescence. The most convenient mode of exhibition is to add to a fluidounce of a mixture consisting of equal parts of lemon juice and water, half a fluidounce of a solution containing fifteen grains of potassium carbonate, or twenty grains of the bicarbonate. Should effervescence not occur, as sometimes happens, when the carbonate is used, in consequence of the weakness of the lemon juice, more of the juice should be added; as, unless sufficient acid be present to neutralize the potassa, part of the carbonate will pass into the state of bicar-

solution is stronger than the mixture, and is more definite in composition; lemon juice varies in strength, and consequently the amount of potassium citrate in the resulting mixture cannot be uniform. On the other hand, the mixture is much to be preferred on account of its more agreeable taste. An improvement has been made in the present official solution in directing the acid and the alkaline salt to be dissolved separately, and the direction to dispense the preparation in a fresh condition will undoubtedly lead to the keeping of the filtered solutions, by the pharmacist, in separate bottles, and mixing in equal measures or weights when prescribed. The solutions keep well for a considerable length of time, and the greater convenience and saving of time and labor, besides the satisfaction of dispensing an effervescing solution, will be strong inducements to adopt this course.

Properties. The U. S. Pharmacopœia describes the solution as "a clear, colorless liquid, odorless, having a mildly saline taste, and a slightly acid reaction. It should conform to the reactions and tests of Potassium Citrate. (See *Potassii Citras.*)" *U. S.* The solution is officially described as containing an indefinite amount of carbonic acid gas: hence the specific gravity cannot be regarded as an accurate test of strength, and is not given in the U. S. P. 1890.

Medical Properties and Uses. The solution of potassium citrate has long been used under the name of *neutral mixture*, *saline mixture*, or *effervescing draught*. It is an excellent refrigerant diaphoretic, adapted to almost all cases of *fever* with a hot dry skin, and especially to the paroxysms of our *remittent* and *intermittent fevers*. The *effervescing draught* (see footnote, p. 819) is peculiarly useful. The carbonic acid serves to cover the taste of the potassium citrate. It is very useful and grateful in allaying irritability of stomach and producing diaphoresis in our *remittent fevers*. In order to increase the sedative and diaphoretic properties of the neutral mixture, one-twenty-fourth to one-sixteenth of a grain of tartar emetic, or one-fourth to one drop of tincture of aconite, may be added to each dose in sthenic cases; and a little sweet spirit of nitre will be found an excellent adjuvant in fevers with nervous disturbance. Should the solution irritate the bowels, it may be combined with an opium preparation. Sugar may be added if desired. The dose of the official solution is half a fluidounce (15 C.c.), which should be somewhat diluted when taken. The whole of each effervescing draught, prepared as above stated, is to be taken at once. Each dose should be repeated every one, two, or three hours, according to the urgency of the symptoms.

LIQUOR POTASSII PERMANGANATIS. Br. Solution of Potassium Permanganate.

(LĪ'QUOR PO-TĂS'SI-Ī PĔR-MĂN-GA-NĀ'TĪS.)

"Potassium Permanganate, 87½ *grains* (Imperial) or 10 grammes; Distilled Water, *a sufficient quantity*. Dissolve the Potassium Permanganate in sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution." *Br.*

This is an unstable 1 per cent. solution of potassium permanganate which decomposes upon exposure and deposits manganese oxides. The Br. Ph. dose is from two to four fluidrachms (3·9–7·8 C.c.), equivalent to from 1·2 to 2·4 grains of the salt. Very few stomachs will bear more than one grain of the permanganate.

LIQUOR QUASSIÆ CONCENTRATUS. Br. Concentrated Solution of Quassia.

(LĪ'QUOR QUÂS'SI-Æ CŎN-CĔN-TRĀ'TŬS.)

"Quassia Wood, in No 40 powder, 2 *ounces* (Imperial) or 100 grammes; Alcohol (20 per cent.), 22 *fl. ounces* (Imp. meas.) or 1100 cubic centimetres or a sufficient quantity. Mix the Quassia with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

bonate, and the gas be prevented from escaping. The fifteen grains of potassium carbonate above mentioned are scarcely sufficient to saturate the lemon juice, if of ordinary strength: but a little excess of the acid renders the preparation more agreeable to the taste. Some prefer the bicarbonate in the preparation of the effervescing draught, because it will always effervesce with lemon juice, no matter what may be the strength of the latter. But this is an objection. The carbonate serves, by the absence of effervescence, to indicate when the lemon juice is very weak in acid; and the defect may then be easily remedied by the addition of more juice. When the bicarbonate is used, if there should be a deficiency of acid, it is not discovered; and the patient takes a considerable portion of undecomposed bicarbonate, instead of the full quantity of citrate intended.

This solution has been introduced into the British Pharmacopœia 1898 mainly to facilitate the preparation of infusion of quassia by diluting the solution with water. (See p. 735.) It may be given in doses of from one-half to one fluidrachm (1·85 to 3·7 C.c.).

LIQUOR RHEI CONCENTRATUS. Br. Concentrated Solution of Rhubarb.

(LĪ'QUOR RHĒ'Ī CŎN-CĔN-TRĀ'TŬS.)

"Rhubarb Root, in No. 5 powder, 10 *ounces* (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 *fl. ounces* (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Rhubarb with *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This solution has been introduced into the British Pharmacopœia to facilitate the preparation of the infusion of rhubarb. (See p. 735.) It fully represents rhubarb, and may be used in doses of from one-half to one fluidrachm (1·85 to 3·7 C.c.).

LIQUOR SARSÆ COMPOSITUS CONCENTRATUS. Br. Concentrated Compound Solution of Sarsaparilla.

(LĪ'QUOR SĂR'SÆ CŌM-PŌŞ'Ī-TŬS CŎN-CĔN-TRĀ'TŬS.)

"Sarsaparilla, cut transversely and bruised, 20 *ounces* (Imperial) or 1000 grammes; Sassafras Root, in shavings, 2 *ounces* (Imp.) or 100 grammes; Guaiacum Wood, in shavings, 2 *ounces* (Imp.) or 100 grammes; Dried Liquorice Root, bruised, 2 *ounces* (Imp.) or 100 grammes; Mezereon Bark, cut small, 1 *ounce* (Imp.) or 50 grammes; Alcohol (90 per cent.), 4½ *fl. ounces* (Imp. meas.) or 225 cubic centimetres; Distilled Water, *a sufficient quantity*. Infuse the Sarsaparilla in three successive portions of *five pints* (Imp. meas.) or five litres of the Distilled Water, for one hour each, at 160° F. (71·1° C.). Boil the other solid ingredients with Distilled Water until exhausted. Rapidly concentrate the mixed infusion and decoction until, when cold, the liquid measures *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres; add the Alcohol; set aside for at least fourteen days; filter. The product should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This preparation has been introduced into the British Pharmacopœia 1898 to provide a reasonably stable solution from which the decoction can be made by dilution. (See p. 479.) Precipitation is apt to occur on standing. The precipitate is, however, inert and may be filtered out. The dose of the solution is from two to eight fluidrachms (7·3 to 29·5 C.c.).

LIQUOR SENEGÆ CONCENTRATUS. Br. Concentrated Solution of Senega.

(LĪ'QUOR SĔN'Ē-ÇÆ CŎN-CĔN-TRĀ'TŬS.)

"Senega Root, in No. 20 powder, 10 *ounces* (Imperial) or 500 grammes; a mixture of two parts of Alcohol (20 per cent.) and one part of Alcohol (45 per cent.), 25 *fl. ounces* (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Senega with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the menstruum; pack in a closed percolator; set aside for three days; percolate with the remaining menstruum, added in ten equal portions at intervals of twelve hours; continue percolation with more menstruum until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This solution has been introduced into the Br. Ph. 1898 for the purpose of providing a method of making the infusion by simple dilution. It represents the medical properties of senega, and may be given in doses of from one-half to one fluidrachm (1·85 to 3·7 C.c.).

LIQUOR SENNÆ CONCENTRATUS. Br. Concentrated Solution of Senna.

(LĪ'QUOR SĔN'NÆ CŎN-CĔN-TRĀ'TŬS.)

"Senna, in No 5 powder, 20 *ounces* (Imperial) or 1000 grammes; Tincture of Ginger, 2½ *fl. ounces* (Imp. meas.) or 125 cubic centimetres; Alcohol (90 per cent.), 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Distilled Water, *a sufficient quantity*. Divide the Senna into three equal portions; slightly moisten one portion with Distilled Water; pack in a percolator;

set aside for twenty-four hours; pass Distilled Water through it until *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres are obtained. Slightly moisten the second portion of Senna with this liquid; pack in a percolator; set aside for twenty-four hours; percolate with the remainder of the liquid obtained from the first portion, and also with an additional *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres obtained by passing more Distilled Water through the first portion. Repeat the process with the third portion of the Senna, and continue successive percolation through the three portions, until a quantity of *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres has been collected from the third percolator. Heat the liquid to 180° F. (82·2° C.) for five minutes; cool; add the Alcohol and Tincture of Ginger, previously mixed; set aside for seven days; filter. The product should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This solution has been introduced into the British Pharmacopœia mainly to provide a strong stable solution from which the infusion may be made by dilution. (See p. 736.) This preparation is an excellent laxative and purgative in doses of from one-half to one fluidrachm (1·85 to 3·7 C.c.).

LIQUOR SERPENTARIÆ CONCENTRATUS. Br. Concentrated Solution of Serpentary.

(LĪ'QUOR SĔR-PĘN-TĀ'RĮ-Æ CŎN-CĔN-TRĀ'TŬS.)

"Serpentary Rhizome, in No. 40 powder, 10 *ounces* (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 *fl. ounces* (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Serpentary with *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This solution has been introduced into the British Pharmacopœia mainly to facilitate the preparation of the infusion. (See p. 737.) It represents the virtues of serpentaria, and may be given in doses of from one-half to two fluidrachms (1·85 to 7·5 C.c.).

LIQUOR SODÆ. U.S. Solution of Soda. [Solution of Sodium Hydrate.]

(LĪ'QUOR SŌ'DÆ.)

"An aqueous solution of Sodium Hydrate [NaOH = 39·96], containing about 5 per cent. of the hydrate." *U. S.*

Liquor Natri Caustici, *P. G.;* Natrum Hydricum Solutum; Soude caustique liquide, *Fr.;* Aetznatronlauge, *G.*

"Sodium Carbonate, *one hundred and seventy grammes* [or 6 ounces av., 153 grains]; Lime, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *a sufficient quantity.* Dissolve the Sodium Carbonate in *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of boiling Distilled Water. Slake the Lime with about *thirty cubic centimeters* [or 1 fluidounce, 7 minims] of Distilled Water, then mix it well with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Distilled Water, pour the mixture into a tared flask, and, having heated it to boiling, gradually add to it the solution of Sodium Carbonate, and boil during ten minutes. Then add enough Distilled Water to the flask to make the contents weigh *one thousand grammes* [or 35 ounces av., 120 grains], and set the flask aside, well stoppered, until the contents are cold. Lastly, strain the liquid through linen, set it aside in a well-stoppered bottle until it has become clear by subsidence, and separate the clear solution by decantation, or by means of a siphon. *Solution of Soda* may also be prepared in the following manner: Soda *fifty-six grammes* [or 1 ounce av., 427 grains]; Distilled Water, *nine hundred and forty-four grammes* [or 33 ounces av., 130 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the Soda in the Distilled Water. The Soda used in this process should be of the full strength directed by the Pharmacopœia (90 per cent.). Soda of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken; the proper amount for the above formula being ascertained by dividing 5000 by the percentage of absolute Soda (sodium hydrate) contained therein. Solution of Soda should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum." *U. S.*

Solution of soda is prepared in the same way as solution of potassa. By a double decomposition between sodium carbonate and calcium hydrate, there are formed sodium hydrate in

solution, and calcium carbonate which precipitates: $Na_2CO_3 + Ca2(HO) = 2NaHO + CaCO_3$. In both the processes an excess of lime is used, which is necessary to insure a full decomposition of the carbonate.

Properties. Solution of soda, sometimes called solution of *caustic* soda, is "a clear, colorless liquid, odorless, having a very acrid and caustic taste, and a strongly alkaline reaction. Specific gravity, about 1·059 at 15° C. (59° F.). It should conform to the same reactions and tests as an aqueous solution of Soda (see *Soda*). To neutralize 20 Gm. of Solution of Soda should require about 25 C.c. of normal sulphuric acid (each C.c. of the volumetric solution indicating 0·2 per cent. of absolute sodium hydrate), phenolphtalein being used as indicator." *U. S.* Its properties and tests are the same as those of solution of potassa, with the exception that no precipitate is produced by platinic chloride or tartaric acid. The alkali dissolved must be viewed as sodium hydrate (Na.OH), of which two molecules are formed by the union of the oxide with water, according to the reaction $Na_2O + H_2O = (Na.OH)_2$.

LIQUOR SODÆ CHLORATÆ. U. S. (Br.) Solution of Chlorinated Soda.

[Labarraque's Solution.]

(LĪ'QUOR SŌ'DÆ ȻHLŌ-RĀ'TÆ.)

"An aqueous solution of several chlorine-compounds of sodium, containing at least 2·6 per cent., by weight, of available chlorine." *U. S.*

Liquor Sodæ Chlorinatæ, *Br., U. S.* 1870; Liquor Natri Chlorati, *P. G.;* Liquor Natri Hypochlorosi; Chlorure de Soude liquide, Liqueur de Labarraque, *Fr.;* Bleichflüssigkeit, *G.*

"Sodium Carbonate, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Chlorinated Lime, *seventy-five grammes* [or 2 ounces av., 282 grains]; Water, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Triturate the Chlorinated Lime with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, gradually added, until a uniform mixture results. Allow the heavier particles to subside, and transfer the thinner, supernatant portion to a filter. Then triturate the residue again with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, transfer the whole to the filter, and when the liquid has drained off, wash the filter and contents with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water. Dissolve the Sodium Carbonate in *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of hot Water, and add this solution to the previously obtained filtrate contained in a suitable vessel. Stir or shake the mixture thoroughly, and, if it should become gelatinous, warm the vessel until the contents liquefy. Then transfer the mixture to a new filter, and, when no more liquid drains from it, wash the filter and contents with enough Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Keep the solution in well-stoppered bottles, protected from light." *U. S.*

"Chlorinated Lime, 16 *ounces* (Imperial) or 400 grammes; Sodium Carbonate, 24 *ounces* (Imp.) or 600 grammes; Distilled Water, 1 *gallon* (Imp. meas.) or 4 litres. Dissolve the Sodium Carbonate in one-quarter of the Distilled Water; thoroughly triturate the Chlorinated Lime with the remainder of the Distilled Water; mix the two liquids; filter." *Br.* The sp. gr. of this solution is 1·054.

This solution was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris. It was afterwards found to possess valuable therapeutic properties. The U. S. process is that of Payen, adopted in the French Codex of 1837. It consists in decomposing a solution of sodium carbonate by one of chlorinated lime. Calcium carbonate is precipitated and the chlorinated soda remains in solution. The proportion employed gives an excess of sodium carbonate, the presence of which renders the solution more permanent. The British process is that of Labarraque. All the chlorine generated from the prescribed quantity of materials for forming that gas is passed into the solution of sodium carbonate; and when the chlorine is limited to this quantity, no carbonic acid is disengaged. The chlorine is first passed through water, to free it from hydrochloric acid, which, if suffered to come over, would convert the alkali into common salt. Sodium bicarbonate has been recommended instead of sodium carbonate, on account of the state of crystalline powder in which the calcium carbonate is precipitated, rendering its separation from the supernatant solution very easy, while the precipitate produced by sodium carbonate is a kind of magma from which the liquor is not readily decanted. It is stated also that a little excess of the bicarbonate is useful in various ways. (*Ann. de Thérap.*, 1866, 107.) Lawall (*A. J. P.*, 1895, 203) prefers the U. S. P. 1880 process to the present official one, as it affords a better preparation in a shorter time.

Properties. The U. S. solution is "a clear, pale greenish liquid, having a faint odor of

chlorine, and a disagreeable, alkaline taste. Specific gravity, about 1·052 at 15° C. (59° F.). The Solution at first colors red litmus paper blue, and then bleaches it. The addition of hydrochloric acid to the Solution causes an effervescence of chlorine and carbonic acid gas. If 6·7 (6·74) Gm. of the Solution be mixed with 50 C.c. of water, then 2 Gm. of potassium iodide and 10 C.c. of hydrochloric acid added, together with a few drops of starch test-solution, it should require not less than 50 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish tint of the liquid (each C.c. of the volumetric solution corresponding to 0·052 per cent. of available chlorine)." *U. S.* "A colorless alkaline liquid, with astringent taste and faint odor of chlorine. It decolorizes *solution of indigo sulphate*. It is decomposed by *hydrochloric acid*, evolving chlorine. It should yield not more than the slightest reaction with the tests for calcium or for carbonates. Specific gravity 1·054. If 3·5 grammes be added to a solution of 1 gramme of *potassium iodide* in 100 cubic centimetres of *water* acidulated with 3 cubic centimetres of *hydrochloric acid*, a brownish-red color should be produced, for the discharge of which at least 25 cubic centimetres of the *volumetric solution of sodium thiosulphate* should be required, corresponding to about 2½ per cent. of available chlorine." *Br.* This test, like that of our own Pharmacopœia, is intended to determine the chlorine strength of the solution. The hydrochloric acid liberates the chlorine, which then liberates from the potassium iodide an equivalent quantity of iodine, by which the solution is rendered brown; and, the iodine being converted into hydriodic acid by the sodium thiosulphate, the solution again becomes colorless. The quantity of the solution of the latter salt required to bleach the liquid measures the amount of iodine, and this that of the chlorine which has separated it. The color of turmeric is first rendered brown, and afterwards destroyed. When carefully evaporated, a mass of damp crystals is obtained, which, when redissolved in water, possesses the properties of the original liquid. Both solutions, when exposed to the air, absorb carbonic acid and slowly evolve chlorine, which acts as a disinfectant.

Nature and Composition. In their chemical nature these solutions are identical. Assuming the chlorinated lime to be essentially calcium hypochlorite with calcium chloride (see page 300), the solutions, after decantation from the precipitated calcium carbonate, will contain *sodium hypochlorite* with *sodium chloride:* $Ca(OCl)_2 + CaCl_2 + (Na_2CO_3)_2 = (CaCO_3)_2 + 2NaOCl + 2NaCl$. Besides these there will be present more or less *sodium carbonate*, according as there happens to be in the chlorinated lime less or more chlorine to decompose it. In all cases, however, there will be an excess of sodium carbonate; as the best chlorinated lime does not contain sufficient chlorine to effect its entire decomposition, in the proportion in which it is taken in the formula. As it is a peculiarity in its formation that no carbonic acid is evolved, it is necessary to assume the presence of all the carbonic acid of the sodium carbonate; and hence it is considered to be a combination of *sodium hypochlorite*, *sodium chloride*, and *sodium bicarbonate*.

Medical Properties and Uses. Solution of chlorinated soda is stimulant, antiseptic, and resolvent. Internally it has been employed in diseases termed putrid or malignant, as *typhus fever*, *scarlatina maligna*, etc. The conditions which have been considered to indicate the propriety of its use are great prostration of strength, fetid evacuations, and dry and furred tongue. It has also been given in *dysentery* accompanied with peculiarly fetid stools, in *dyspepsia* attended with putrid eructations, and in *glandular enlargements* and chronic mucous discharges. Other complaints in which it has been recommended are secondary *syphilis*, *scrofula*, bilious disorders, and chronic diseases of the skin. In hydrogen sulphide poisoning it is, like chlorinated lime, an efficacious antidote. The dose is from thirty drops to a teaspoonful, given in a cupful of water or mild aqueous liquid.

As a local remedy it is found useful in all affections attended with fetor, such as gangrenous, cancerous, scrofulous, and syphilitic *ulcers*, ulceration of the gums, *carbuncle*, *ozæna*, mortification, *putrid sore throat*, *ptyalism*, etc. In these cases it is applied as a gargle, wash, ingredient of poultices, or imbibed by lint. In fetid discharges from the vagina, uterus, and bladder, it has been employed with advantage as an injection, diluted with from fifteen to thirty parts of water for the vagina and uterus, and with sixty parts when the object is to wash out the bladder by means of a double canula. The solution of chlorinated soda has also been applied successfully to burns, and to cutaneous eruptions, particularly *psoriasis*, *tinea capitis*, *scabies*, and obstinate *herpetic affections*, and to allay itching and fetor in *small-pox*. In these cases it is diluted with from ten to thirty parts of water, the strength varying according to circumstances. For the cure of *sore nipples*, Dr. Chopin found nothing so successful as frequently repeated lotions with this solution. Glycerin is in many instances preferable as a diluent to water, as it tends

to prevent irritation of the sound skin, and does not evaporate like water. Solution of chlorinated soda is a powerful disinfectant. In the chambers of the sick it is highly useful, if put in the vessels intended to receive the excretions.

LIQUOR SODII ARSENATIS. U. S., Br. Solution of Sodium Arsenate.

(LĪ'QUOR SŌ'DI-Ī ĂR-SĒ-NĀ'TĬS.)

Liquor Sodii Arseniatis, *Br.* 1885; Solution of Arseniate of Sodium; Liqueur (Soluté) d'Arséniate de Soude, *Fr.;* Arsensaure Natronlösung, *G.*

"Sodium Arsenate, deprived of its water of crystallization by a heat not exceeding 149° C. (300·2° F.), *one gramme* [or 15·4 grains]; Distilled Water, *a sufficient quantity*, To make *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Dissolve the Sodium Arsenate in a sufficient quantity of Distilled Water to make *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]." *U. S.*

"Sodium Arsenate, recently rendered anhydrous, 17½ *grains* (Imperial) or 1 gramme; Distilled Water, *a sufficient quantity*. Dissolve the anhydrous Sodium Arsenate in sufficient Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution of Sodium Arsenate. 110 minims contain 1·77 grains of crystallized sodium arsenate, ($Na_2HAsO_4,7H_2O$,) or the equivalent of 1 grain of the anhydrous salt. 100 cubic centimetres contain 1·77 grammes of the crystallized salt, equivalent to 1 gramme of the anhydrous salt." *Br.*

This is simply an official form for the administration of sodium arsenate. (See *Sodii Arsenas.*) The present official solution is somewhat stronger than that of the U. S. P. 1870. It now contains 1 per cent. of sodium arsenate, where formerly there was present but 0·87 per cent., and the British solution has been made to correspond in strength. The salt is directed to be dried, in order that the solution may be of a uniform strength; as, from the mode in which the sodium arsenate is ordered to be prepared, it is scarcely possible that it should always contain precisely the same quantity of water of crystallization. It is important in drying it to limit the heat to 300° F., lest a portion of the arsenic should be volatilized. Dose, from three to five minims (0·18–0·3 C.c.), to be cautiously increased, if necessary.

LIQUOR SODII ETHYLATIS. Br. Solution of Sodium Ethylate.

(LĪ'QUOR SŌ'DI-Ī ĔTH-Y-LĀ'TĬS.)

"Sodium, clean and bright, 22 *grains* (Imperial) or 1 gramme; Absolute Alcohol, 1 *fl. ounce* (Imp. meas.) or 20 cubic centimetres. Cautiously dissolve the Sodium in the Absolute Alcohol contained in a flask, the latter being kept cool by a stream of cold water." *Br.*

This solution was a new official of the British Pharmacopœia 1885. It is described as "A colorless liquid of syrupy consistence, becoming brown by keeping. Specific gravity 0·867. When slightly heated it boils and gives off alcoholic vapors, leaving a white residue which, on being strongly heated, becomes charred. If the white residue be mixed with *water* and heated, it yields ethylic alcohol, and the solution, on evaporation, leaves a white residue consisting almost wholly of caustic soda. This solution should be recently prepared. It contains 18 per cent. of the solid substance, C_2H_5ONa." It may be made more conveniently by dissolving twenty grains of sodium ethylate in eighty grains of absolute alcohol. It is used solely as a caustic, and is said to produce very little pain. No water should be allowed to come in contact with it.

LIQUOR SODII SILICATIS. U. S. Solution of Sodium Silicate.

(LĪ'QUOR SŌ'DI-Ī SĬL-I-CĀ'TĬS.)

Solution of Silicate of Sodium; Silicate de Soude liquide, *Fr.;* Flüssiges Wasserglas, *G.*

This solution is not a preparation which can be conveniently made by the pharmacist, therefore no process is given. Under the head of *Sodium Silicate* (PART II.) will be found the method of preparing and purifying it.

Properties. The Pharmacopœia describes the solution as "a semi-transparent, almost colorless, or yellowish, or pale greenish-yellow, viscid liquid, odorless, having a sharp, saline, and alkaline taste, and an alkaline reaction. Specific gravity, 1·300 to 1·400 at 15° C. (59° F.). A drop of the Solution, when held in a non-luminous flame, imparts to it an intensely yellow color. If a portion of the Solution, largely diluted with water, be supersaturated with nitric acid, a gelatinous or pulverulent, white precipitate of silicic hydrate will be produced." *U. S.*

This solution is used solely in the preparation of mechanical dressings by the surgeon.

LIQUOR STRYCHNINÆ HYDROCHLORIDI. Br. Solution of Strychnine Hydrochloride. [Solution of Hydrochlorate of Strychnine, Brit. Pharm. 1885.]

(LĪ'QUOR STRĬĆH-NĪ'NÆ HĬ-DRO-ĆHLŌ'RĮ-DĪ.)

"Strychnine Hydrochloride, 17½ *grains* (Imperial) or 1 gramme; Alcohol (90 per cent.), 1 *fl. ounce* (Imp. meas.) or 25 cubic centimetres; Distilled Water, *a sufficient quantity*. Dissolve the Strychnine Hydrochloride in the Alcohol mixed with sufficient Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution of Strychnine Hydrochloride. 110 minims contain 1 grain of Strychnine Hydrochloride; 100 cubic centimetres contain 1 gramme." *Br.*

This is the solution of hydrochlorate of strychnine of the British Pharmacopœia which was formerly official as *Liquor Strychniæ:* the name has been made definite, and the strength slightly increased, so as to make it conform with the other active solutions: it contains 1 per cent. of strychnine. The spirit is added for its preservation. A change was made in the last revision of the Br. Pharm. 1898 whereby strychnine hydrochloride is dissolved directly in water containing a little alcohol. This is said to prevent the tendency of the solution to crystallize in cold weather, a fault of the Br. Ph. 1885 process. The commencing dose is from five to ten minims (0·3–0·6 C.c.), equal respectively to about the twenty-fourth and the twelfth of a grain (0·0025–0·005 Gm.) of the alkaloid.

LIQUOR THYROIDEI. Br. Thyroid Solution.

(LĪ'QUOR THĬ-RŌĬ'DĒ-Ī.)

"A liquid prepared from the fresh and healthy thyroid gland of the sheep." *Br.*

"Remove the external fat and connective tissue from thyroid glands taken from sheep immediately after killing; cut the glands across, and reject any that contain cysts, are hypertrophied, or are otherwise abnormal. Count the healthy glands that remain; slice them and bruise them thoroughly in a mortar; for each entire gland (consisting of two lobes) add *thirty-four minims* or two cubic centimetres of Glycerin, and *thirty-four minims* or two cubic centimetres of a 0·5 per cent. solution of Phenol in Distilled Water; transfer the mixture, well stirred, to a flask, and close the neck with a plug of Cotton Wool; allow it to stand for twenty-four hours; then strain through linen, with strong pressure; add to the strained liquid sufficient of the 0·5 per cent. solution of Phenol to make *one hundred minims* or six cubic centimetres of the Solution for each gland used." *Br.*

This solution, introduced into the British Pharmacopœia 1898, is intended to represent the activity of the thyroid gland. It is described as a "pinkish turbid liquid, entirely free from any odor of putrescence. It must be freshly prepared, and kept in well-stoppered, sterilized bottles. 100 *minims* or 6 cubic centimetres represent one entire thyroid gland." *Br.*

For its medical properties, see *Thyroideum Siccum.*

LIQUOR ZINCI CHLORIDI. U. S., Br. Solution of Zinc Chloride.

(LĪ'QUOR ZĬN'ĆĪ ĆHLŌ'RĮ-DĪ.)

"An aqueous solution of Zinc Chloride [$ZnCl_2 = 135{\cdot}84$], containing about 50 per cent., by weight, of the salt." *U. S.*

Chlorure de Zinc liquide, Soluté de Burnett, *Fr.;* Flüssiges Chlorzink, *G.*

"Zinc, granulated, *two hundred and forty grammes* [or 8 ounces av., 204 grains]; Hydrochloric Acid, *eight hundred and forty grammes* [or 29 ounces av., 275 grains]; Nitric Acid, *twelve grammes* [or 185 grains]; Precipitated Zinc Carbonate, *twelve grammes* [or 185 grains]; Distilled Water, *a sufficient quantity*. To the Zinc, contained in a glass or porcelain vessel, add *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Distilled Water; then gradually add the Hydrochloric Acid, and digest, until the Acid is saturated; pour off the solution, add the Nitric Acid, evaporate the solution to dryness, and heat the dry mass to fusion at a temperature not exceeding 115° C. (239° F.). Let it cool, and dissolve it in a sufficient amount of Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Then add the Precipitated Zinc Carbonate, agitate the mixture occasionally during twenty-four hours, and then set it aside until it has become clear by subsidence. Finally, separate the clear solution by decantation, or by means of a siphon." *U. S.*

"Granulated Zinc, 1 *pound* (Imperial) or 400 grammes; Hydrochloric Acid, 44 *fl. ounces* (Imp. meas.) or 1100 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the Hy-

drochloric Acid with *one pint* (Imp. meas.) or 500 cubic centimetres of Distilled Water in a porcelain dish; add the Zinc; apply gentle heat until gas is no longer evolved; boil for half an hour, supplying the water lost by evaporation; allow the product to cool. Test a few drops of the resulting liquid for iron and lead.

"If either be present, filter the remainder of the product into a bottle, and add *solution of chlorine* by degrees, with frequent agitation, until the liquid acquires a permanent odor of chlorine; add Zinc Carbonate in small quantities at a time, with renewed agitation, until a brown sediment appears and the whole of the iron or lead is thus precipitated; filter the liquid into a basin, and evaporate to the bulk of *two pints* (Imp. meas.) or one thousand cubic centimetres. If no iron or lead be present, filter the cooled product and evaporate it to *two pints* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The zinc chloride is made in the usual way, by dissolving zinc in hydrochloric acid. The nitric acid in the U. S. process is added in order that any iron present shall be converted into ferric chloride, from which it is afterwards precipitated by the zinc carbonate. In the older processes the former object was accomplished by the use of solution of chlorinated lime, the latter by chalk. This is a decided improvement, as the use of the chalk as a precipitant introduced into the preparation some calcium chloride, while the zinc carbonate adds only a little zinc chloride in solution. Hydrogen dioxide has been used instead of nitric acid as an oxidizing agent by Besthorn and others. The preparation is completed by bringing it to a certain bulk by the addition of distilled water, and by filtration to separate the precipitated iron and any excess of the carbonate. As procured by the U. S. P. process, solution of zinc chloride is "a clear, colorless liquid, odorless, having a very astringent, sweetish taste, and an acid reaction. Specific gravity about 1·535 at 15° C. (59° F.). It conforms to the reactions and tests of an aqueous solution of Zinc Chloride (see *Zinci Chloridum*)." "A colorless liquid of astringent and sweetish taste. Specific gravity 1·530. It should respond to the tests for zinc and for chlorides. It should not yield any characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, or sulphates." *Br.* The British solution contains about 175 grains of zinc in the Imperial fluidounce. The American solution does not differ much, containing about 170 grains to the fluidounce (wine measure). This solution is equivalent to Burnett's disinfecting fluid noticed below. It is a powerful disinfectant, and, when applied, duly diluted with water, to cancerous and other offensive *ulcers*, destroys their fetor so long as the dressings are kept moist with it. The solution is recommended by M. Gaudriot in *gonorrhœa* in both sexes, as having remarkable remedial powers. For men he uses an injection, composed of from twenty-four to thirty-six drops in four fluidounces of water. A small quantity only is injected about an inch up the urethra, two or three times a day. For women he employs a vaginal suppository, formed of five drops of the solution, half a grain of morphine sulphate, and three drachms of a paste consisting of a drachm and a half of starch, a drachm of mucilage of tragacanth, and half a drachm of sugar. The suppository is introduced every day, or every second day.

Burnett's disinfecting fluid, like the official solution, is an aqueous solution of zinc chloride. It contains 200 grains of zinc in each Imperial fluidounce, and has the sp. gr. 2. It is, therefore, considerably stronger than the Dublin solution. It is so called after Sir William Burnett, who introduced it into use, in 1840, as a powerful deodorizing and disinfecting agent in neutralizing noxious effluvia and in arresting animal and vegetable decomposition. Diluted with water it forms Sir William's patent preservative against the dry-rot. The concurrent testimony of a number of observers shows that it acts as an excellent disinfectant for ships, hospitals, dissecting-rooms, water-closets, privies, etc. Injected into the blood-vessels, it preserves bodies for dissection, without impairing their texture, and is said not to injure the knives employed; but the accuracy of the latter statement is doubtful. The advantage is claimed for it that, while it destroys putrid odors, it has no smell of its own. For preserving anatomical subjects, one part of the disinfecting fluid to eighteen of water will form a solution of the proper strength. For disinfecting operations on a large scale, a pint may be mixed with four gallons of water.

LITHII BENZOAS. U. S. Lithium Benzoate.

$LiC_7H_5O_2$; 127·72. (LĬTH'Ĭ-Ī BĔN'ZŌ-ĂS.) $LiC_7H_5O_2$; 128.

Benzoate de Lithium, *Fr.*; Benzoësaures Lithon, *G.*

This salt of lithium is made by decomposing lithium carbonate with benzoic acid. E. B. Shuttleworth (*A. J. P.*, 1875) deviates from the usual method of first making a hot solution of benzoic acid and then adding carbonate until effervescence ceases, by reversing the order.

One ounce (av.) of lithium carbonate is put into a capsule with nine fluidounces of water, the mixture is heated, and three and a quarter ounces (av.) of benzoic acid in small portions added, until the carbonate is all decomposed and effervescence ceases: the solution is filtered and evaporated to dryness, or crystallized if desired. The yield is three and a half ounces. The advantage of this process is a saving in time and labor in evaporating: $Li_2CO_3 + 2HC_7H_5O_2 = 2LiC_7H_5O_2 + H_2O + CO_2$. No process is given in the Pharmacopœia. The official description is as follows.

Properties. "A light, white powder, or small, shining, crystalline scales; odorless, or of faint benzoin-like odor, and of a cooling, sweetish taste; permanent in the air. Soluble, at 15° C. (59° F.), in 4 parts of water, and in 12 parts of alcohol; in 2·5 parts of boiling water, and in 10 parts of boiling alcohol. The presence of sodium benzoate increases the solubility in water and lessens that in alcohol. When heated, the salt fuses; at a higher temperature it chars, emits inflammable vapors having a benzoin-like odor, and finally leaves a residue of lithium carbonate mixed with carbon. This residue imparts a crimson color to a non-luminous flame, and its aqueous solution has an alkaline reaction upon litmus paper. The aqueous solution (1 in 20) of Lithium Benzoate has a faintly acid reaction upon litmus. If 2 C.c. of ferric chloride test-solution be mixed with a small drop of ammonia water, and added to 2 C.c. of an aqueous solution of the salt, a voluminous brownish-pink precipitate of basic ferric benzoate will result. If 1 C.c. of diluted nitric acid be added to 0·2 Gm. of Lithium Benzoate dissolved in 2 C.c. of water, and the precipitated benzoic acid be removed by filtration, the clear filtrate should not be rendered turbid on the addition of silver nitrate test-solution (absence of *chloride*), or of barium nitrate test-solution (absence of *sulphate*). If a concentrated solution of the salt be mixed with hydrochloric acid, a white precipitate of benzoic acid will be formed, which, after being separated from the liquid, and thoroughly washed and dried, should respond to the tests of purity given under *Acidum Benzoicum*. If the filtrate from this precipitate be evaporated to dryness and ignited, 1 part of the residue should be soluble in 5 parts of absolute alcohol. If to this alcoholic solution an equal volume of ether be added, no precipitate or turbidity should appear (limit of *other alkalies*). The aqueous solution (1 in 20) of the salt should remain unaffected by hydrogen sulphide test-solution, or ammonium sulphide test-solution (absence of *arsenic*, *lead*, *iron*, *aluminum*, etc.), or by ammonium oxalate test-solution (absence of *calcium*), or by sodium cobaltic nitrite test-solution (limit of *potassium*); nor should silver nitrate test-solution, or barium nitrate test-solution, produce in it more than a very slight turbidity (limit of *chloride* and *sulphate*). If 1 Gm. of dry Lithium Benzoate be thoroughly ignited in a porcelain crucible, so as to burn off most of the carbonaceous matter, and the residue be mixed with 20 C.c. of water, it should require, for complete neutralization, not less than 7·8 C.c. of normal sulphuric acid (corresponding to not less than 99·6 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* Curtman states that much of the lithium benzoate in the market contains not only sodium benzoate, but also hippurate, derived from urine-benzoic acid. This renders it much more soluble in water than the pure salt, and also more soluble in alcohol. The precipitated benzoic acid should melt at 121·4° C.; hippuric acid, if pure, melts at 187·5° C. Hence a high melting point for the separated benzoic acid points to this source of contamination.

Medical Properties. Lithium benzoate has been highly commended as a remedy against *gout* (*Edin. Med. Journ.*, Jan. 1875), and has been used to some extent: there is, however, no sufficient reason for supposing that it is superior to the citrate or carbonate of the base. Dose, from fifteen to thirty grains (1–1·95 Gm.).

LITHII BROMIDUM. U. S. Lithium Bromide.

Li Br; 86·77. (LĬTH′Ĭ-Ī BRŌ′MĬ-DŬM.) Li Br; 86·8.

Bromure de Lithium, *Fr.*; Bromlithium, *G.*

This salt was made official in the U. S. P. 1880. Yvon prepares lithium bromide by mixing 37 parts of lithium carbonate, 200 parts of distilled water, and 80 parts of bromine, and passing a current of hydrogen sulphide through the mixture until the color of bromine has disappeared. A slight heat is then applied, to drive off excess of hydrogen sulphide and to agglutinate the sulphur. After filtration the liquor is concentrated and finally crystallized by desiccating it under a bell-glass, over sulphuric acid. It may also be obtained by double decomposition. Lithium sulphate is first formed by treating 37 parts of lithium carbonate with 49 parts of monohydrated sulphuric acid diluted with its own volume of water. Then 119 parts of potassium bromide are dissolved in the smallest possible quantity of water. When the two solu-

tions are mixed, an abundant precipitate of potassium sulphate is produced on the addition of a little alcohol. The whole is evaporated to dryness, the operation finished on a water-bath, and the residue is treated with alcohol, which removes only lithium bromide and deposits it again on evaporation. The bromide may then be crystallized from water or kept in solution of known strength.* (*P. J. Tr.*, Sept 18, 1876.) No process is given in the Pharmacopœia. "Lithium Bromide should be kept in well-stoppered bottles." *U. S.*

Properties. "A white, granular salt, odorless, and having a sharp, slightly bitter taste; very deliquescent. Soluble, at 15° C. (59° F.), in 0·6 part of water, and in 0·3 part of boiling water; very soluble in alcohol; also soluble in ether. At a low red heat the salt fuses, and at a higher heat it is slowly volatilized. It imparts a crimson color to a non-luminous flame. The aqueous solution is neutral to litmus paper. If a few drops of chloroform be added to 5 C.c. of the solution (1 in 20), then 1 C.c. of chlorine water, and the mixture shaken, the liberated bromine will dissolve in the chloroform, communicating to it a yellow or yellowish-brown color. If 0·5 C.c. of sodium cobaltic nitrite test-solution be added to 5 C.c. of the aqueous solution, no precipitate or turbidity should occur within 10 minutes (limit of *potassium*). One part of the salt should dissolve, without residue, in 5 parts of absolute alcohol, and the addition of an equal volume of ether should produce no precipitate in this solution (limit of *other alkalies*). The aqueous solution (1 in 20) should not be affected by hydrogen sulphide test-solution either before or after acidulation with a drop of hydrochloric acid (absence of *arsenic*, *lead*, *copper*, etc.), nor by ammonium sulphide test-solution (absence of *iron*, *aluminum*, etc.). In the aqueous solution no turbidity should be produced by the addition of barium chloride test-solution (absence of *sulphate*). If a few drops of starch test-solution be added to 5 C.c. of the aqueous solution, and then a drop or two of chlorine water, no blue color should appear (absence of *iodide*). If 0·3 Gm. of dry Lithium Bromide be dissolved in 10 C.c. of water and 2 drops of potassium chromate test-solution be added, it should require 35·3 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color of silver chromate (corresponding to at least 98 per cent. of the pure salt)." *U. S.*

Medical Properties. Lithium bromide was first brought into notice as a remedy by Dr. S. Weir Mitchell, who asserts that its action differs from that of the other bromides only in being more hypnotic. Although careful physiological studies of it are wanting, there is little reason for believing that it differs essentially from other bromides in its influence upon the human organism. It should be administered in dilute aqueous solution, in doses of from fifteen to thirty grains (1–1·95 Gm.). Each drachm of it contains fifty-five grains of bromine, and it therefore exceeds potassium bromide in bromine strength.

LITHII CARBONAS. U. S., Br. Lithium Carbonate.

Li_2CO_3; 73·87. (LĬTH'Ĭ-Ī CĂR'BŌ-NĂS.) Li_2CO_3; 74.

"Lithium Carbonate, Li_2CO_3, is obtained from native silicates of lithium." *Br.*

Lithium Carbonicum, *P. G.;* Carbonas Lithicus; Carbonate of Lithia, *E.;* Carbonate de Lithine, Carbonate lithique, *Fr.;* Kohlensaures Lithon, *G.*

The alkali *lithia*, so far as has yet been ascertained, is rare in nature; for, though extensively diffused, it exists in very small proportion, except in a few scarce minerals. It was discovered by Arfvedson in 1817, in certain minerals from the iron-mines of Utö, as *petalite*, *triphane*, and a variety of *tourmaline*. (*Berzelius.*) It has since been found in other minerals, as *lepidolite*, *spodumene*, *amblygonite*, etc., and in numerous mineral waters, as those of Carlsbad, Pyrmont, Kissingen, Kreuznach, Aix-la-Chapelle, Vichy, etc., in Europe, and the Gettysburg spring in the United States, in which it exists generally as a carbonate or a bicarbonate. By spectrum analysis it has been detected in the waters of the Atlantic and of the Thames, in the ashes of plants grown on a granite soil, and even in milk and human blood. In the mother-waters of tartaric acid, in the factories, it has been found in a proportion to justify extraction. It was at one time largely obtained from a *phosphatic triphyline* found in Bavaria, in which it existed as a phosphate; but this source is said to have been exhausted. There are several methods

* *Lithium Iodide* (LiI: 133·6) may be prepared by taking of iodine 127 parts, iron, in filings, 35 parts, lithium carbonate 38 parts, distilled water 300 parts. Prepare a solution of ferrous iodide, using the whole of the distilled water, filter, add the lithium carbonate to the still warm liquid, and heat gently to promote complete decomposition. The liquid must be slightly alkaline. Filter, wash the precipitated ferrous carbonate, add the washings to the filtrate, evaporate the latter, pour it out to cool and harden, and immediately transfer it into well-dried, glass-stoppered vials. It forms a white salt very soluble in water and alcohol. One gramme of it is entirely precipitated by 1·27 Gm. of silver nitrate. (*N. R.*, July, 1877.)

of extracting lithia from the minerals containing it, an account of which may be seen in *Roscoe and Schorlemmer*, vol. ii., Part I., p. 158. They contain the alkali in various proportions, from 3·6 per cent. in lepidolite to 11 per cent. in amblygonite. Lithium carbonate is prepared from lepidolite in the following manner. 10 parts of finely powdered lepidolite, 10 parts of barium carbonate, 5 parts of barium sulphate, and 3 parts of potassium sulphate are fused at a very high temperature in a wind furnace. The heavy barium silicate and sulphate sink to the bottom, and a layer of potassium and lithium sulphates is found at the top of the fused mass. These can be extracted by simple lixiviation, and then the carbonate prepared by double decomposition with ammonium carbonate.

Lithia, Li_2O, is the oxide of the metal lithium, and ranks in chemical properties with the fixed alkalies. In the form of hydrate, LiOH, it is white and translucent; does not deliquesce in the air, but absorbs carbonic acid, and becomes opaque; is fusible below ignition, but not volatilizable at a white heat; is soluble in water, but less so than potassa or soda; is sparingly soluble in alcohol; and in solution has an acrid alkaline taste, caustic properties, and a strong alkaline reaction. The salts of lithium are generally freely soluble, with the exception of the neutral carbonate and phosphate, the latter of which is nearly insoluble. *Lithium*, which was first obtained by Bunsen and Matthiessen, in 1855, is silver-white, brilliant, softer than lead, ductile, capable of welding, and the lightest known solid. Its sp. gr. is 0·594, melting point 180° C. (356° F.), atomic weight 7·01, and symbol Li.

Lithium carbonate may be prepared directly from one of the lithia minerals, in the manner already described, or from lithium sulphate or chloride in concentrated solution by adding ammonium carbonate. The precipitated salt should be washed with alcohol and dried.

Properties. It is "a light, white powder, odorless, and having an alkaline taste; permanent in the air. Soluble in 80 parts of water at 15° C. (59° F.), and in 140 parts of boiling water;* much more soluble in water saturated with carbon dioxide; insoluble in alcohol; soluble in diluted acids with active effervescence. At a low red heat the salt fuses; at a higher temperature it loses some of its carbon dioxide, and is partially converted into lithium oxide. It imparts a crimson color to a non-luminous flame. The aqueous solution has an alkaline reaction upon litmus paper. If 1 Gm. of Lithium Carbonate be dissolved in 40 C.c. of diluted acetic acid, no insoluble residue should remain. Separate portions of this solution should not be affected by the following reagents: hydrogen sulphide test-solution (absence of *arsenic*, *lead*, etc.); ammonium sulphide test-solution (absence of *iron*, *aluminum*, etc.); ammonium oxalate test-solution (*calcium*); silver nitrate test-solution (*chloride*); barium chloride test-solution (*sulphate*); or sodium cobaltic nitrite test-solution (limit of *potassium*). If 0·5 Gm. of Lithium Carbonate be dissolved in 2 C.c. of hydrochloric acid, and the clear solution be evaporated to dryness, the dry residue should completely dissolve in 3 C.c. of absolute alcohol, and an addition of 3 C.c. of ether should not render the solution turbid (limit of *other alkalies*). If 0·5 Gm. of the dry salt be mixed with 20 C.c. of water, it should require, for complete neutralization, not less than 13·4 C.c. of normal sulphuric acid (corresponding to at least 98·98 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* "In white powder or in minute crystalline grains, soluble in about 70 parts of cold *water*, insoluble in *alcohol* (90 per cent.). Its aqueous solution turns *red litmus paper* blue. It is dissolved with effervescence by *hydrochloric acid;* the solution evaporated to dryness leaves a residue, which communicates a crimson color to flame. This residue redissolved in water yields a precipitate with *solution of sodium phosphate.* 1 gramme of the salt neutralized with *sulphuric acid* and afterwards heated to redness leaves 1·479 grammes of dry lithium sulphate, corresponding to 98·5 per cent. of the pure carbonate. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, zinc, magnesium, sodium, potassium, ammonium, or chlorides, and only the slightest reactions with the tests for calcium and for sulphates." *Br.* Its aqueous solution has an alkaline reaction.†

Medical Properties and Uses. Lithium carbonate has the ordinary remedial properties of the alkaline carbonates, over which, however, it possesses advantages, under certain

* Prof. F. A. Flückiger states that lithium carbonate is less soluble in warm water than in cold water. He recommends as a test of purity that it should require for solution 70 parts or a little more of water at 15° C., and states further that its solution saturated at 90° C. has the sp. gr. 1·009 at 15° C.: this latter solution contains 1 part of the salt in 111·3 parts of water. (*Archiv d. Pharm.*, 1887, p. 509.)

† *Effervescing Lithium Carbonate.* Take of Citric Acid 40 parts, Sodium Bicarbonate 50 parts, and Lithium Carbonate 10 parts. Powder and mix well, then introduce into a wide flat-bottomed dish, and heat to about 100° C. (212° F.), stirring constantly until the powder becomes granular. Separate the granules of uniform size by means of appropriate sieves, and preserve them in well-stopped bottles.

circumstances, which render it a valuable addition to the materia medica. In the year 1843, Mr. Alexander Ure, of London, called attention to the extraordinary solvent power of a solution of lithia over uric acid, with which, unlike the other alkalies, it forms a very soluble salt, and suggested its injection into the bladder, for the solution or disintegration of *uric acid calculi*. In 1857, Dr. Garrod, of London, gave it internally in cases of *gout* and *gouty diathesis* in reference to the same property, as well as in consideration of its low combining number and consequent extraordinary neutralizing power. From these properties, it is admirably adapted to cases in which it is desirable to eliminate uric acid from the system, and especially to cases of gout, in which there is a strong indication to prevent the formation of insoluble salts of uric acid, and their deposition in the bladder, kidneys, or joints, and to favor the solution of such salts when already formed, as in the chalky deposits in the joints and ligamentous tissues of gouty patients, consisting chiefly of sodium urate. Dr. Garrod has, moreover, found lithium carbonate, in dilute solution, not only to exceed the other alkalies in rendering the urine neutral or alkaline, but also to act powerfully as a diuretic, probably more so than the corresponding salts of potassium and sodium. (*Med. Times and Gaz.*, March, 1864, p. 303.) The dose of lithium carbonate is from five to fifteen grains (0·32 to 1 Gm.), and is most advantageously given in carbonic acid water.

LITHII CITRAS. U. S., Br. Lithium Citrate.

$Li_3C_6H_5O_7$; 209·57. (LĬTH'Ĭ-Ī CĬ'TRĂS.) $Li_3C_6.H_5O_7$; 210.

Citrate of Lithium; Lithium Citricum; Citrate of Lithia, *E.;* Citrate de Lithine, *Fr.;* Citronensaures Lithium, *G.*

"Lithium Citrate should be kept in well-stoppered bottles." *U. S.* "Lithium Citrate, $C_3H_4.OH.(COOLi)_3.4H_2O$, is prepared by saturating citric acid with lithium carbonate." *Br.*

To saturate the 50 grains of lithium carbonate directed by the British Pharm. (1885) 90·54 grains of the crystallized acid will be required: so that there is a slight deficiency on the part of the acid, whereas it should be in slight excess, and, according to Mr. Squire, 100 grains of the acid should be used instead of 90 grains. (See, also, *P. J. Tr.*, Sept. 11, 1875.) This proportion was employed in the U. S. Pharmacopœia process of 1870. See foot-note.*

Mr. C. Umney (*P. J. Tr.*, Sept. 11, 1875) advocates the use of the crystallized salt in place of that made by either of the official processes. He obtained it by setting aside a solution of the sp. gr. 1·230, when a salt crystallized out having the formula $Li_3C_6H_5O_7.4H_2O$: it is described as definite and reliable as found in commerce, and "not deliquescent." (See, also, *P. J. Tr.*, 1883, p. 783.)

Properties. Lithium citrate is in the form of a white powder, "odorless, and having a cooling, faintly alkaline taste; deliquescent on exposure to air. Soluble in 2 parts of water at 15° C. (59° F.), and in 0·5 part of boiling water; almost insoluble in alcohol or ether. At a red heat the salt chars, emits inflammable vapors of a pungent odor, and finally leaves a black residue of lithium carbonate mixed with carbon. It imparts a crimson color to a non-luminous flame. The aqueous solution is neutral to litmus paper. If the aqueous solution (1 in 20) of Lithium Citrate be boiled with an equal volume of calcium chloride test-solution, a white precipitate will be deposited. Separate portions of the solution, slightly acidulated with acetic acid, should not be affected by hydrogen sulphide test-solution (absence of *arsenic*, *lead*, etc.); ammonium sulphide test-solution (*iron*, *aluminum*, etc.); ammonium oxalate test-solution (*calcium*); or sodium cobaltic nitrite test-solution (limit of *potassium*). With barium nitrate test-solution, or with silver nitrate test-solution, not more than a slight turbidity should appear (limit of *sulphate* and of *chloride*). If the residue obtained by calcining the salt at a red heat be dissolved in a slight excess of diluted hydrochloric acid, and the filtrate evaporated to dryness, a portion of the residue, treated with 5 parts of absolute alcohol, should completely dissolve, and the addition of an equal volume of ether should not render the solution turbid (limit of *other alkalies*). If 1 Gm. of dry Lithium Citrate be thoroughly ignited in a porcelain crucible, so as to burn off most of the carbonaceous matter, and the residue be mixed with 20 C.c. of water, it should require, for complete neutralization, not less than 14·2 C.c. of normal sulphuric acid (corresponding to at least 99·2 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* "2 grammes of the salt dried at 212° F. (100° C.) should lose about 0·38

* "Take of Carbonate of Lithium *one hundred grains;* Citric Acid, in crystals, *two hundred grains;* Distilled Water *two fluidounces.* Dissolve the Citric Acid in the water gently heated, and to the solution gradually add the Carbonate of Lithium until perfectly dissolved, heating the solution so long as effervescence is produced. Evaporate, by means of a steam- or sand-bath, to a viscid consistence, dry the residue in an oven, at a temperature of about 240°, then rapidly pulverize it, and preserve the powder in a well-stopped bottle." *U. S.* 1870.

gramme; at 240° F. (115·5° C.) an additional 0·13 gramme; and, when burned at a low red heat with free access of air, should leave 0·77 gramme of white residue, corresponding to 98·5 per cent. of the pure citrate. It should be free from the impurities mentioned under 'Lithii Carbonas.'" *Br.* That the salt is a citrate will be shown by its solution becoming turbid when boiled with lime water, but clear again on cooling. (Brande and Taylor.)

Medical Properties and Uses. These are essentially the same as those of the carbonate, as the citric acid is burnt up in the system and a lithium carbonate formed, which is finally eliminated by the kidneys. While thus acting like the carbonate, it has the advantages over that salt of having a less disagreeable taste and of being less disposed to irritate the stomach, —the same advantages that, in many instances, potassium citrate has over the carbonate of that alkali. The dose is from ten to thirty grains (0·65–1·95 Gm.).

LITHII CITRAS EFFERVESCENS. U. S., Br. Effervescent Lithium Citrate.

(LĬTH'Ị-Ī CĪ'TRĂS ĔF-FẸR-VĔS'CẸNṢ.)

"Lithium Carbonate, *seventy grammes* [or 2 ounces av., 205 grains]; Sodium Bicarbonate, *two hundred and eighty grammes* [or 9 ounces av., 384 grains]; Citric Acid, *three hundred and seventy grammes* [or 13 ounces av., 22 grains]; Sugar, in fine powder, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Triturate the Citric Acid with about *two hundred grammes* [or 7 ounces av., 24 grains] of Sugar, and dry the mixture thoroughly. Then incorporate with it, by trituration, the Lithium Carbonate and Sodium Bicarbonate, and enough Sugar to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Keep the product in well-stoppered bottles." *U. S.*

"Sodium Bicarbonate, in powder, 58 *ounces* (Imperial) or 580 grammes; Tartaric Acid, in powder, 31 *ounces* (Imp.) or 310 grammes; Citric Acid, in powder, 21 *ounces* (Imp.) or 210 grammes; Lithium Citrate, 5 *ounces* (Imp.) or 50 grammes. Mix the Lithium Citrate with the Citric Acid, then add the Tartaric Acid, and, lastly, the Sodium Bicarbonate, triturating thoroughly. Place the whole in a dish or pan of suitable form heated to between 200° and 220° F. (93·3° and 104·4° C.). When the mixture, by the aid of careful manipulation, has assumed a granular character, separate it, by means of suitable sieves, into granules of uniform and convenient size. Dry the granules at a temperature not exceeding 130° F. (54·4° C.). The product should weigh about 100 *ounces* (Imp.) or 1000 grammes." *Br.*

These official processes do not yield identical products, the U. S. preparation containing sugar, which, in our opinion, is objectionable. There seems to be no good reason for employing both citric and tartaric acids in the British process. The U. S. process yields a powder, whilst that of the British Pharmacopœia produces a granular salt which is more desirable for administration.

This effervescent salt forms an agreeable method of administering the lithia salts; its medical properties are those of lithium citrate, and the dose is a teaspoonful in water.

LITHII SALICYLAS. U. S. Lithium Salicylate.

$LiC_7H_5O_3$; 143·68. (LĬTH'Ị-Ī SĂL-Ị-CĪ'LĂS.) $2LiC_7H_5O_3.H_2O$; 306.

No process is given in the Pharmacopœia for this official salt. It may be prepared by adding to a mixture of eleven parts of salicylic acid and three parts of lithium carbonate twenty-five parts of water, and heating until effervescence ceases, filtering and evaporating. It may be obtained in crystals, and "should be kept in well-stoppered bottles." *U. S.*

Properties. "A white or grayish-white powder, odorless, and having a sweetish taste; deliquescent on exposure to air. Very soluble in water and in alcohol. When heated, the salt is decomposed, emitting the odor of phenol, and finally leaving a residue of lithium carbonate and carbon. It imparts a crimson color to a non-luminous flame. The aqueous solution slightly reddens blue litmus paper. If copper sulphate test-solution be added to an aqueous solution (1 in 20) of the salt, the mixture should have a bright-green color. If a small quantity of ferric chloride test-solution be added to an excess of a concentrated, aqueous solution (1 in 4) of Lithium Salicylate, a deep red color will be produced, which, after the liquid is largely diluted and mixed with more ferric chloride test-solution, will change to a deep bluish-violet tint. Upon adding to 1 Gm. of the salt, in a test-tube, about 1 C.c. of concentrated sulphuric acid, then, cautiously, in drops, about 1 C.c. of methylic alcohol, and heating the mixture to boiling, the odor of oil of gaultheria will be evolved. Hydrochloric or sulphuric acid produces in the aqueous solution a voluminous precipitate of salicylic acid, which, when separated and washed,

should conform to the reactions and tests given under *Acidum Salicylicum*. The aqueous solution should be colorless (absence of *iron* and *organic coloring matters*), and should not effervesce on the addition of diluted acids (absence of *carbonate*). If 1 part of the salt be agitated with 15 parts of sulphuric acid, no color should be imparted to the acid within 15 minutes (absence of *readily carbonizable, organic impurities*). If a portion of the residue, left after ignition, be dissolved in diluted acetic acid, separate portions of the filtrate should not be rendered turbid on the addition of a few drops of barium chloride test-solution (absence of *sulphate*), nor be rendered more than very slightly turbid by silver nitrate test-solution (limit of *chloride*). Other portions of the same filtrate should not be affected by hydrogen sulphide test-solution (absence of *arsenic, lead*, etc.); nor by ammonium sulphide test-solution (*aluminum*, etc.); nor by ammonium oxalate test-solution (*calcium*); nor by sodium cobaltic nitrite test-solution (limit of *potassium*). If another portion of the residue, left after ignition, be dissolved in diluted hydrochloric acid, and the filtrate evaporated to dryness, a portion of the residue, when treated with 5 parts of absolute alcohol, should completely dissolve, and the addition of an equal volume of ether should not render the solution turbid (limit of *other alkalies*). If 2 Gm. of dry Lithium Salicylate be thoroughly ignited in a porcelain crucible, so as to burn off most of the carbonaceous matter, and the residue be mixed with 20 C.c. of water, it should require, for complete neutralization, not less than 13·8 C.c. of normal sulphuric acid (corresponding to at least 99·13 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.*

Medical Properties. This salt has probably been introduced into the Pharmacopœia as a remedy in *gout* and *rheumatism*, uniting the virtues of salicylic acid and of lithium. It will probably be found efficient, and has the great advantage over salicylic acid of being freely soluble in water and much less irritant to the stomach. Every drachm of it contains about 57·25 grains of salicylic acid and 2·75 grains of lithium. The dose is from twenty to forty grains (1·3–2·6 Gm.), to be given in an aromatized syrup.

LOBELIA. U. S., Br. Lobelia.

(LŌ-BĒ′LI-Ą.)

"The leaves and tops of Lobelia inflata, Linné (nat. ord. Lobeliaceæ), collected after a portion of the capsules have become inflated." *U. S.* "The dried flowering herb of Lobelia inflata, Linn." *Br.*

Herba Lobeliæ, *P. G.;* Indian Tobacco; Herbe de Lobélie enflée, *Fr.;* Lobelienkraut, *G.*

Lobelia inflata. L. *Sp. Pl.* (1753) 931; Willd. *Sp. Plant.* i. 946; Bigelow, *Am. Med. Bot.* i. 177; Barton, *Med. Bot.* i. 181; Carson, *Illust. of Med. Bot.* i. 60, pl. 51; *B. & T.* 162. This species of Lobelia, often called *Indian tobacco*, is an annual or biennial indigenous plant, usually a foot or more in height, with a fibrous root, and a solitary, erect, angular, very hairy stem, much branched about midway, but rising considerably above the summits of the highest branches. The leaves are scattered, or alternate, petiolate, the upper sessile, ovate, or oblong, about two inches (5 Cm.) long, irregularly toothed, pubescent, pale green. The flowers are numerous, small, disposed in leafy terminal racemes, and upon short axillary footstalks. The calyx is five-toothed and much inflated in fruit. The corolla, which is of a delicate blue, has a labiate border, with the upper lip divided into two, the lower into three segments. The united anthers are curved, and enclose the stigma. The fruit is an oval, striated, inflated capsule, crowned with the persistent calyx, and containing, in two cells, numerous very small, oblong, reticulated brown seeds.* The transverse section of the stem exhibits laticiferous vessels in the bast. According to Engler and Prantl, the genus Lobelia belongs to the nat. ord. Campanulaceæ.

Lobelia inflata† is a very common weed, growing on the roadsides and in neglected fields throughout the United States and Canada. Its flowers begin to appear towards the end of

* In case of poisoning by lobelia, the seeds may be recognized by the following microscopic characters. (Fred. Curtis, *Lond. Med. Gaz.*, July, 1851.) They are almond-shaped, about 1-30th of an inch long by 1-75th broad, puce-colored, regularly marked with longitudinal ridges and furrows, and cross ridges generally at right angles with the former, so that the surface presents the appearance of basket-work. No other seeds could be mistaken for them, except those of *Lobelia cardinalis*, which, however, are larger, coarser, of a lighter color, and with the superficial rectangular checkering less distinct.

† Two other North American species of lobelia have been used in medicine, but appear to be of very little value,—*L. cardinalis*, or cardinal flower, as an anthelmintic; *L. syphilitica*, as an antisyphilitic. (See Dr. W. P. C. Barton's *Medical Botany.*) Mr. V. Rosen has found in the *L. nicotianæfolia*, which grows in the mountain ranges of Ceylon and the Madras peninsula, two alkaloids,—one liquid and identical with lobeline, the other a crystalline solid. He believes, as the result of some physiological experiments, that the plant has the same properties as those of *L. inflata.* (*P. J. Tr.*, 1886, p. 838.)

July, and continue to expand in succession till the occurrence of frost. All parts of it are medicinal; but, according to Dr. Eberle, the root and inflated capsules are most powerful. The plant should be collected in August or September, when the capsules are numerous, and should be carefully dried. It may be kept whole or in powder As found in commerce, it is often in oblong compressed cakes, prepared by the Shakers or the herb-dealers.

Dried lobelia has a slightly irritating odor, and when chewed, though at first without much taste, soon produces a burning acrid impression upon the posterior parts of the tongue and palate, very closely resembling that occasioned by tobacco, and attended in like manner with a flow of saliva and a nauseating effect. "Leaves alternate, petiolate, the upper ones sessile, ovate or oblong, about 5 Cm. long, irregularly toothed, pubescent, pale green; branches hairy, terminating in long racemes of small, pale blue flowers, having an adherent five-toothed calyx, which is inflated in fruit, a bilabiate corolla, and five united stamens; odor slight, irritating; taste mild, afterwards burning and acrid." *U. S.* The powder is greenish. The plant yields its virtues readily to water and alcohol. Water distilled from it has its odor without its acrimony. Prof. Procter found the plant to contain an odorous volatile principle, probably volatile oil; a peculiar alkaline principle, named lobeline; a peculiar acid, first noticed as distinct by Pereira, called *lobelic acid;* besides gum, resin, chlorophyll, fixed oil, lignin, salts of lime and potassa, and oxide of iron. The seeds contain at least twice as much of lobeline, in proportion, as the whole plant, which yielded only one part in five hundred. They contain also 30 per cent. of a nearly colorless fixed oil having the drying property in an extraordinary degree. *Lobeline* was obtained by Prof. Procter by the following process. The seeds were treated with alcohol acidulated with acetic acid, until deprived of acrimony, and the tincture was evaporated; the resulting extract was triturated with magnesia and water, and, after repeated agitation for several hours, the liquor, holding lobeline in solution, was filtered; this was then shaken repeatedly with ether until no longer acrid; and the ethereal solution, having been decanted, was allowed to evaporate spontaneously. The residue, which was reddish brown and of the consistence of honey, was deprived of coloring matter by dissolving it in water, adding a slight excess of sulphuric acid, boiling with animal charcoal, saturating with magnesia, filtering, agitating with ether until this fluid had deprived the water of acrimony, and finally decanting, and allowing the ether to evaporate. Thus obtained, *lobeline* is a yellowish liquid, lighter than water, of a somewhat aromatic odor, and a very acrid durable taste. It is soluble in water, but much more copiously in alcohol and ether; and the latter fluid readily removes it from its aqueous solution. It has an alkaline reaction, and forms soluble and crystallizable salts with sulphuric, nitric, and hydrochloric acids, and a very soluble but not crystallizable salt with acetic acid. It forms an insoluble compound with tannic acid, which instantly precipitates it from its solution. By a boiling heat it is entirely decomposed, losing all its acrimony; but when combined with acids it may be subjected to ebullition with water without change. (*A. J. P.*, ix. 105, xiii. 1; see, also, a paper by W. D. Richardson, Jr., *A. J. P.*, 1872, p. 293.).* Paschkis and Smita (*Monatshefte*, xi. p. 131) obtained the alkaloid as a viscous oil with an odor resembling at once that of honey and that of tobacco. Siebert has also obtained both from the herb and seeds of lobelia a pale-yellow alkaline syrup, the crystallized hydrochloride and chloroplatinate of which indicated the formula $C_{18}H_{23}NO_2$ for the free alkaloid. Enders has also isolated the acrid substance of the drug, and gives to it the name *lobelacrin.* It is obtained in warty tufts of a brown color, soluble in ether and chloroform, but only slightly in water. It is decomposed by boiling with dilute acids or alkalies into sugar and lobelic acid. Lewis (*P. J. Tr.* [3], 10, p. 56) considers lobelacrin as only a mixture of lobeline lobeliate with free lobelic acid. (*Pharmacographia*, 2d ed., 400.) Lloyd considers the lobelacrin of Enders to be a mixture of inflatin, resin, lobeline, and the fixed oil which lobelia contains in the proportion of about 30 per cent. The late Dr. S. Colhoun, of Philadelphia, was the first to announce the existence of a peculiar principle in lobelia, capable of forming salts with the acids; but he did not obtain it in an isolated state. An important inference from the effects of heat upon lobeline is that, in preparing lobelia for use, the plant should never be heated in connection with a salifiable base. Prof. J. U. Lloyd isolated from lobelia a crystalline substance, melting at 225° C., which had been observed previously by Prof. Procter. Prof. Lloyd named it *inflatin;* it is colorless, tasteless, and odorless, insoluble in water or glycerin, soluble in carbon disulphide,

* Mr. William Bastick, of London, published (*P. J. Tr.*, Dec. 1850) an article on lobeline, apparently in entire ignorance of the previous work of Prof. Procter. His process does not differ essentially from that above given. In one magnesia is used to decompose the native salt of lobeline, in the other lime, the caustic alkalies not being applicable to the purpose, as they decompose this alkaloid with great facility.

benzene, chloroform, ether, and least soluble in alcohol. It is a neutral principle, and appears to have no therapeutic value. (*Pharm. Rundschau*, 1887, 32.)

Medical Properties and Uses. Lobelia is said to have been used as a medicine by the aborigines of America, but was first brought into general professional notice by the Rev. Dr. Cutler, of Massachusetts. The leaves or capsules, chewed for a short time, occasion giddiness, headache, general tremors, and ultimately nausea and vomiting. When swallowed in the full dose, the medicine produces speedy and severe vomiting, attended with continued and distressing nausea, copious sweating, and great general relaxation. When toxic doses are taken, these symptoms are very severe, and have added to them burning pain in the fauces or œsophagus, progressive failure of voluntary motion, rapid, feeble pulse, fall of temperature, and finally collapse with stupor or coma; in some cases convulsions precede death. Death has often resulted from its empirical use. Its poisonous effects are most apt to occur when, as sometimes happens, it is not rejected by vomiting. The experiments of Dr. I. Ott upon the lower animals show that the poison causes paralysis of the motor nerve-trunks, of the peripheral vagi, and probably also of the vaso-motor centres. Death seems to occur from failure of respiration, due, in part at least, to the condition of the motor nerves.

As an emetic, lobelia should never be used; at present it is rarely employed at all except in *spasmodic asthma*, the paroxysms of which it often greatly mitigates, and sometimes wholly relieves, even when not given in doses sufficiently large to vomit. It has been used also in *catarrh*, *croup*, *pertussis*, and other *laryngeal* and *pectoral affections*, but is chiefly valuable where there is *bronchial spasm:* it must always be employed with caution. The tincture affords the most eligible mode of administration; in asthmatic cases it may be given in doses of fifteen minims (0·9 C.c.) every hour until an effect is produced. The fluid extract and the tincture are official. The process for the vinegar, which was dropped by the U. S. Pharmacopœia of 1890, will be found in the foot-note.* Dr. Nunes (*T. G.*, 1889) asserts that he has used lobeline in a number of cases of *asthma* with most excellent results in doses of from three-fourths of a grain to six grains a day; but it can scarcely be doubted that he had a very impure alkaloid, and that such doses of a pure sample would be highly dangerous.

LOTIONES. Lotions.

(LŌ-TI̤-Ō'NĒŞ—lō-shę-ō'nēz.)

Washes; Lotions, *Fr.;* Waschungen, *G.*

This class has been introduced into the British Pharmacopœia in order to give official recognition to two preparations, the *black wash*, or *lotio nigra*, and the *yellow wash*, or *lotio flava*, which have been long in use, and which will be found treated of under Calomel and Corrosive Sublimate at pages 688 and 693 of this work. Nothing more is necessary here than to give the British formulas.

LOTIO HYDRARGYRI FLAVA. Br. Yellow Mercurial Lotion.

(LŌ'TI̤-Ō HĬ-DRĂR'ĢI̤-RĪ FLĀ'VĄ—lō'shę-ō.)

Aqua Phagedænica, *P. G.;* Yellow Wash; Eau phagédénique, Eau divine de Fernel, Phagédénique, *Fr.;* Phagedänisches Wasser, Altschadenwasser, *G.*

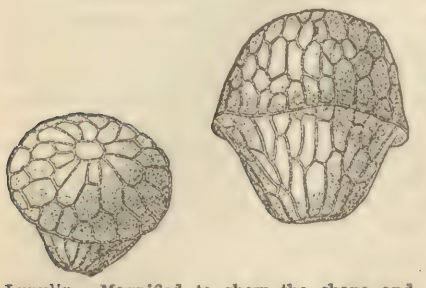
"Mercuric Chloride, 20 *grains* (Imperial) or 0.46 gramme; Solution of Lime, 10 *fl. ounces* (Imp. meas.) or 100 cubic centimetres. Mix." *Br.* (See *Lotio Flava*, National Formulary.) This lotion is about 11 per cent. stronger than that official in the Br. Ph. 1885.

LOTIO HYDRARGYRI NIGRA. Br. Black Mercurial Lotion.

(LŌ'TI̤-Ō HĬ-DRĂR'ĢI̤-RĪ NĪ'GRĄ.)

Aqua Phagedænica Nigra, *P. G.;* Aqua Nigra, Aqua Mercurialis Nigra; Black Wash; Eau phagédénique noire, *Fr.;* Schwarzes Wasser, *G.*

"Mercurous Chloride, 30 *grains* (Imperial) or 0·685 gramme; Glycerin, ½ *fl. ounce* (Imp. meas.) or 5 cubic centimetres; Mucilage of Tragacanth, 1½ *fl. ounces* (Imp. meas.) or 12·5



* *Acetum Lobeliæ*, U. S. 1880. *Vinegar of Lobelia.* (*Vinaigre de Lobélie enflée*, Fr.; *Lobelien-Essig*, G.) "Lobelia, in No. 30 powder, *ten parts* [or one and three-fourths ounces av.]; Diluted Acetic Acid, *a sufficient quantity*, To make *one hundred parts* [or one pint]. Moisten the powder with *five parts* [or one fluidounce] of Diluted Acetic Acid, pack it firmly in a conical glass percolator, and gradually pour Diluted Acetic Acid upon it until *one hundred parts* [or one pint] of filtered liquid are obtained." *U. S.* Vinegar of Lobelia may also be prepared by macerating the powder in one pint of Diluted Acetic Acid for seven days, expressing the liquid, and filtering through paper. This is an active preparation of lobelia. Dose, as an expectorant for an adult, from thirty minims to a fluidrachm (2–3·75 C.c.). In the paroxysm of spasmodic *asthma* from one to two fluidrachms (3·75–7·50 C.c.) may be given every two or three hours till relief is obtained.

cubic centimetres; Solution of Lime, *a sufficient quantity*. Triturate the Mercurous Chloride with the Glycerin and Mucilage of Tragacanth; transfer to a bottle; add *two fluid ounces* (Imp. meas.) or 20 cubic centimetres of the Solution of Lime; shake well; add sufficient Solution of Lime to produce *ten fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Lotion." *Br.* (See *Lotio Nigra*, National Formulary.) The addition of glycerin and mucilage of tragacanth improves this lotion by aiding in the suspension of the insoluble powder.

LUPULINUM. U. S., Br. Lupulin.

(LŪ-PŪ-LĪ'NŬM.)

"The glandular powder separated from the strobiles of Humulus Lupulus, Linné (nat. ord. Urticaceæ)." *U. S.* "Glands obtained from the strobiles of Humulus Lupulus, Linn. It should contain not more than 40 per cent. of matter insoluble in *ether*, and yield not more than 12 per cent. of ash when incinerated." *Br.*

Lupulin. Magnified, to show the shape and markings of the granules.

Lupulina, *Pharm.* 1870; Lupulinic Glands; Glandulæ Lupuli, *P. G.;* Lupuline, Lupulite, *Fr.;* Hopfenmehl, Lupulin, *G.*

Lupulin is officially described as "bright brownish yellow, becoming yellowish brown, resinous, consisting of minute granules, which, as seen under the microscope, are subglobular, or rather hood-shaped, and reticulate; aromatic and bitter. When Lupulin is agitated with water and the mixture allowed to stand, no considerable sediment (sand, etc.) should be deposited. When ignited, Lupulin should not leave more than 10 per cent. of ash." *U. S.* (See *Humulus*, p. 685.)*

LYCOPODIUM. U. S. Lycopodium.

(LĬ-CŌ-PŌ'DĮ-ŬM.)

"The spores of Lycopodium clavatum, Linné, and of other species of Lycopodium (nat. ord. Lycopodiaceæ)." *U. S.*

Vegetable Sulphur; Semen Lycopodii, Pulvis Lycopodii, Sulphur Vegetabile; Lycopode, Soufre végétal, Pied de Loup, *Fr.;* Gemeiner Bärlapp, Kolbenmoos, Bärlappsamen, Streupulver, Hexenmehl, *G.;* Licopodio, *It., Sp.*

Lycopodium clavatum. Linn. *Sp. Plant.* (1753) 1101; *B. & T.* 299. This plant, commonly called *club-moss*, has a trailing, branching stem, several feet long, and thickly beset with linear-lanceolate, flat, ribless, smooth, partly serrate leaves with a capillary point, curved upward, and of a deep green color. The fructification is in terminal spikes, single or in pairs, with crowded ovate, entire, pointed scales, bearing in the axil a transversely oval sporange which splits nearly to the base and contains the narrow reticulate spores. The plant is a native of Europe, Asia, and America.

The spores are collected in Switzerland and Germany. Lycopodium is "a fine powder, pale yellowish, very mobile, inodorous, tasteless, floating upon water and not wetted by it, but sinking on being boiled with it, and burning quickly when thrown into a flame. Under the microscope the spores are seen to be sphæro-tetrahedral, the surfaces marked with reticulated ridges, and the edges beset with short projections. Lycopodium should be free from pollen, starch, sand, and other impurities, any of which are easily detected by means of the microscope. When ignited with free access of air, Lycopodium should not leave more than 5 per cent. of ash." *U. S.* Bucholz in 1807 pointed out the existence of a fixed oil. Flückiger, however, by thoroughly comminuting the spores of lycopodium with sand, obtained 47 per cent. of a bland oil of bright yellow color and sp. gr. 0·925, which does not congeal even at —15° C. (5° F.). Stenhouse found volatile bases to be present in very small amount. The ash amounts to 4 per cent. It contains alumina and 1 per cent. of phosphoric acid, and is not alkaline. (*Pharmacographia*, 2d ed., 732.) Lycopodium is often adulterated with the pollen of the pines and firs, and sometimes with talc and starch. In Nashville, Tenn.,

A, Pollen-cell of *Picea excelsa; B*, Lycopodium.

* Mr. J. S. Ward found, as the results of an examination, four samples of lupulin, which fairly represent the commercial article, to yield 54·24, 41·49, 40·04, and 39·41 per cent. of extractive, soluble in ether, and to yield 27·01, 29·10, 30·86, and 31·42 per cent. of ash. The samples were all gritty. (*P. J. Tr.*, 1886, 656.)

a specimen came into the possession of Mr. Benj. Lillard which was found to contain one-half of its bulk of dextrin. (*Chicago Pharmacist*, Sept. 1873.) Folleto recommends two reactions to detect pollen: one by adding to a syrupy solution of zinc chloride potassium iodide and iodine to saturation; the pollen is colored yellow by this reagent, lycopodium is not colored; the other reagent is methyl-green, which colors pollen green, but does not color lycopodium. (*Pharm. Central.*, 1896, 527.) Lycopodium is used as an absorbent application to *excoriated surfaces*, especially those which occur in the folds of the skin in infants. In pharmacy it answers the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. The moss itself has been esteemed diuretic and antispasmodic: its decoction has been employed in *rheumatism*, *diseases of the lungs and kidneys*, and in the removal of *plica Polonica;* but it has fallen into complete desuetude.

MACIS. U. S. Mace.

(MĀ'CĬS.)

"The arillode of the fruit of Myristica fragrans, Houttuyn (nat. ord. Myristicaceæ)." *U. S.*

Arillus Myristicæ; Macis, Fleur de Muscade, *Fr.;* Muskatblüthe (Macis), *G.;* Macis, *It.;* Macias, *Sp.*

Mace occurs "in narrow bands, 25 Mm. or more long, somewhat branched and lobed above, united into broader bands below; brownish-orange; fatty when scratched or pressed; odor fragrant, taste warm and aromatic." *U. S.* Examined with the microscope, mace will be found to be largely made up of uniform, small, angular, parenchymatous cells, interspersed with numerous brown oil-cells of larger size. The inner part of the tissue contains also thin brown vascular bundles. The cells of the epidermis on either side are colorless, thick-walled, longitudinally extended, and covered with a peculiar cuticle of broad, flat, ribbon-like cells, which cannot, however, be removed as a continuous film. The parenchymatous cells are loaded with small albuminous granules, but do not contain starch. In examining ground mace these elements of structure come out plainly, and the presence of starch granules or other microscopic particles different from those spoken of is proof that the powdered mace has been adulterated.* Mace contains from 7 to 9 per cent. of a volatile oil, the greater portion of which consists of *pinene*, along with which is some *myristicin*, $C_{12}A_{14}O_2$. Wallach also found a fixed oil, odorous, yellow, soluble in ether, insoluble in boiling alcohol; another fixed oil, odorous, red, soluble in alcohol and ether in every proportion; a peculiar gummy matter; and a small proportion of ligneous fibre. Flückiger finds that, instead of the fats just described, there is about 25 per cent. of resin. (*Pharmacographia*, 509.) Mace yields a volatile oil by distillation and a fixed oil by pressure. Neumann found the former heavier than water. The latter is less consistent than the fixed oil of nutmeg. Mace is inferior when it is brittle, less than usually divided, whitish or pale yellow, or with little taste and smell. (See *Myristica.*)

MAGNESIA. U. S. (Br.) Magnesia. [Light Magnesia. Calcined Magnesia.]

MgO; 40·26. (MĂG-NĒ'ŞĮ-Ą.) MgO; 40.

"Light Magnesium Oxide, MgO, is prepared by exposing Light Magnesium Carbonate to a dull red heat." *Br.*

Magnesia Levis, *Br.;* Magnesia Usta, *P.G.;* Magnesia Calcinata; Magnésie, Magnésie calcinée, *Fr.;* Gebrannte Magnesia, *G.*

In the British Pharmacopœia 1885 directions were given for preparing two forms of magnesia, one called *Magnesia Levis*,† or *Light Magnesia*, from the *Light Carbonate*, and the other *Magnesia Ponderosa*, from the *Heavy Carbonate.* It is the former which corresponds with our ordinary magnesia. Neither Pharmacopœia gives a detailed process.

By exposure to a red heat, the water and carbonic acid of the magnesium carbonate are ex-

* Occasionally mace is adulterated with powdered Bombay or wild mace, or with vegetable matters stained with turmeric. According to Hefelmann, the presence of Bombay mace, or of turmeric, may be infallibly detected by the following test. A strip of filtering paper is saturated with the alcoholic solution, the excess of liquid removed by pressing between filtering paper, and the strip drawn through a cold saturated solution of boric acid; if the adulterant be Bombay mace the paper remains unchanged, while turmeric changes the color to orange or even brown. The addition now of a drop of potassium hydrate solution to the strip causes a colored ring—with turmeric, blue; with Bombay mace, red. (*Pharm. Zeit.*, 1891.) For additional tests, see *P. J. Tr.*, 1897, 288.

† "Take of Light Carbonate of Magnesium *four ounces.* Put it into a Cornish or Hessian crucible closed loosely by a lid, and expose it to a low red heat until a small quantity, taken from the centre of the crucible, cooled, moistened with water, and dropped into warm diluted sulphuric acid, causes no effervescence." *Br.* 1885.

pelled, and the earth is obtained pure. According to Dr. Black, the carbonate loses seven-twelfths of its weight by calcination. Brande says that the loss varies from 50 to 60 per cent., of which from 15 to 20 per cent. is water: $(MgCO_3)_4 + Mg(OH)_2 + 5H_2O = 5MgO + 6H_2O + 4CO_2$. About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbonic acid. (*Duncan.*) A more certain indication, however, is the absence of effervescence when hydrochloric acid is added to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbonic acid, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine. In order to insure a pure product, care should be taken that the carbonate employed be free from lime. It should be rubbed to powder before being introduced into the pot or crucible; and, as in consequence of its levity it occupies a very large space, the plan has been proposed of moistening and compressing it in order to reduce its bulk; but the French pharmaceutical writers direct that the vessels employed should be sufficiently large to contain a considerable quantity of the carbonate, without the necessity of resorting to compression.* The official direction, to keep the magnesia, after it has been prepared, in well-closed vessels, is founded on the fact that it absorbs carbonic acid and water from the air; but, as the absorption of the acid goes on very slowly, and that of water does not injure the preparation, the caution is often neglected. The great bulk of the earth renders its introduction into small bottles inconvenient. A four-ounce bottle holds only about an ounce of the purest and finest magnesia. But its specific gravity is greatly increased by trituration; and four times the quantity may be thus got into the same space. The density of *Henry's Magnesia*, which is at least four times that of the earth prepared in the ordinary way, has been ascribed to this cause. It has also been attributed to the influence of intense heat employed in the calcination. The conjecture has even been advanced, that this magnesia, which has enjoyed so great a popularity in England and this country, is prepared by precipitating a solution of magnesium sulphate by caustic potassa, as the earth afforded by this plan is comparatively dense. It is asserted that the magnesia prepared from the carbonate procured by precipitating magnesium sulphate with potassium carbonate is softer to the touch and bears a closer resemblance to Henry's than that prepared from the ordinary carbonate. The fact is explained by the presence in such magnesia of a little potassium sulphate, from which it is difficult entirely to free it in consequence of the sparing solubility of this salt, and of a portion of silica, which originally existed in the potassium carbonate employed to decompose the magnesium sulphate, and of which sodium carbonate is destitute. According to Mr. Richard Phillips, Jr., if equivalent quantities of crystallized magnesium sulphate and crystallized sodium carbonate be boiled together in water, the mixture evaporated to dryness, the residual salts calcined, and the sodium sulphate dissolved out by water, the magnesia obtained will be dense. (See *A. J. P.*, xvi. 118.) By packing the carbonate closely in the crucible, or by moistening and then compressing it strongly in a cloth, before calcination, a heavy magnesia is obtained. The advantages of Henry's magnesia, independently of the convenience of its less bulk, are its greater softness and more ready miscibility with water. A preparation similar to Henry's is made by T. J. Husband, of Philadelphia. In reference to the preparation of heavy magnesia, Mr. T. H. Barr, after trying various methods, obtained the best results either by precipitating a hot concentrated solution of magnesium sulphate with a like solution of sodium carbonate, or by decomposing magnesium chloride by heat. (*A. J. P.*, xxvi. 193.) Dr. P. E. Alessandri proposes the following method, which is both simple and rapid, for preparing "heavy" calcined magnesia. Take ordinary calcined magnesia, free from carbonate, moisten it, in a mortar, with pure, absolute alcohol, and triturate it, at first gently, afterwards with some force, but not rapidly. During the agitation, the magnesia is to be moistened three or four times with fresh portions of the alcohol, and the operation is suspended when the bulk of the magnesia appears to remain stationary. Then

* In a paper by M. A. Vée (*Journ. de Pharm.*, Avril, 1860, p. 84) it is stated that the magnesia of commerce, in consequence of imperfect preparation, is often found dense, granular, harsh, and of difficult solubility in the acids. To remedy this inconvenience the only method heretofore known was to prepare it in small quantities, and to stir the magnesia during calcination with an iron spoon. The difficulty in preparing it properly on the large scale depends upon the unequal action of the heat on large masses, so that the outer part becomes heated in excess before the inner is sufficiently so. To remedy this inconvenience, M. Vée uses a furnace and crucible of a peculiar shape, so arranged that the magnesia may not be in layers thicker than seven centimeters (2·7 inches), may be exposed equably to heat, and not longer exposed than may be necessary for its decomposition. For an account of the apparatus, and of the proper method of management, see *A. J. P.*, 1862, p. 522.

remove the mass, dry it, rub it to powder, and pass it through a sieve. The product occupies only about one-fifteenth of the original bulk. (*N. R.*, March, 1882.)

Magnesia is now manufactured extensively in the United States, the domestic product having almost entirely supplanted that which was formerly imported from Great Britain. The Keasbey & Mattison Company have erected extensive works at Ambler, Pa., although the greater part of their output is magnesium carbonate, which is used in the arts mainly as a non-conductor of heat. This company also makes light and heavy calcined magnesia for medicinal purposes, and dolomite is now exclusively used as the source of the magnesium compounds. (See *Magnesii Carbonas* for further information.)

Dr. Pereira found *light magnesia*, under the microscope, to exhibit the same forms observed in the light carbonate: namely, one portion was amorphous and of a flocculent or granular consistence, and another was composed of fragments of prismatic crystals; while the *heavy magnesia* was homogeneous, exhibiting no traces of crystals, and consisting of minute granules more or less cohering into small soft balls or masses. (*P. J. Tr.*, viii. 235.)

Properties. Magnesia is a very light, white, inodorous powder, of a feeble alkaline taste. Its sp. gr. is commonly stated at 2·3. It was deemed infusible till melted by means of the compound blowpipe of Dr. Hare. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature. It is almost insoluble, requiring, according to Dr. Fyfe, 5142 parts of water at 60° F., and 36,000 parts of boiling water, for solution. Water thus impregnated has no effect on vegetable colors; but magnesia itself produces a brown stain by contact with moistened turmeric paper. Magnesia is a metallic oxide, consisting of one atom of magnesium and one of oxygen. It is officially described as "almost insoluble in water, and insoluble in alcohol, but soluble in dilute acids. It is not altered by heat, but when very strongly heated its density is increased. When moistened with water, it has a faintly alkaline reaction upon litmus paper. On stirring 1 part of Magnesia with 15 parts of water, in a beaker, and allowing the mixture to stand for about half an hour, it will form a gelatinous mass of sufficient consistence to prevent it from dropping out when the glass is inverted. A filtered solution of Magnesia in diluted sulphuric acid, mixed with ammonium chloride test-solution and an excess of ammonia water, yields, with sodium phosphate test-solution, a white, crystalline precipitate. If a mixture of 0·2 Gm. of Magnesia with 10 C.c. of water be heated to boiling, and, after cooling, 5 C.c. of the supernatant liquid be filtered off, this filtrate should not give more than a faintly alkaline reaction with litmus paper, and, when evaporated to dryness, should not leave more than a very slight residue (limit of *foreign soluble salts*). The Magnesia mixed with water remaining from the preceding test, when poured into 5 C.c. of acetic acid, should dissolve without the evolution of more than a few isolated gas bubbles (limit of *carbonate*). This latter solution, when filtered, should not be rendered more than slightly opalescent by ammonium oxalate test-solution (limit of *calcium*), or by barium chloride test-solution (limit of *sulphate*), or, after the addition of a few drops of nitric acid, by silver nitrate test-solution (limit of *chloride*). If 0·4 Gm. of Magnesia be dissolved in 10 C.c. of diluted hydrochloric acid, the solution should be colorless, and should not be affected by hydrogen sulphide test-solution, nor, after the addition of a slight excess of ammonia water, should it be immediately affected by ammonium sulphide test-solution (absence of *metallic impurities*). If Magnesia be exposed to a low red heat in a porcelain crucible, it should not lose more than 5 per cent. of its weight (limit of *water of hydration*)." *U. S.* "A bulky white powder differing from Heavy Magnesia only in its greater lightness, the volumes corresponding to the same weight being to each other in the ratio of three and a half to one." *Br.*

Magnesium is a white, very brilliant metal, of sp. gr. 1·75, resembling silver, malleable, fusible at a low temperature, and convertible into magnesia by the combined action of air and moisture. It burns with great facility, and yields by its combustion a light which is intensely white and very rich in actinic or chemically active rays, so that it finds wide application in signal lights and for photography, although the cheaper alloy of magnesium and zinc is often used instead. There is a magnesium hydrate, possessing the formula $Mg(OH)_2$. With nitric and hydrochloric acids magnesia forms salts which are soluble in alcohol and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydrate, and by potassium and sodium carbonates as a carbonate; but it is not precipitated by the alkaline bicarbonates, nor by common ammonium carbonate.

Magnesia is liable to contain, as impurities, magnesium carbonate, lime, alumina, silica, and small quantities of the soluble salts employed or produced in the preparation of the carbonate from which it is procured. Lime, which is a very frequent impurity, and imparts to the mag-

nesia a more strongly alkaline and more disagreeable taste, is detected by ammonium oxalate or potassium bicarbonate. Neither of these salts disturbs a neutral solution of pure magnesia in a dilute acid; but if lime is present, both produce a precipitate, the former of oxalate, the latter of calcium carbonate. But, according to Wittstein, calcium oxalate is soluble in the neutral salts of magnesia, requiring 50 parts of magnesium chloride, and 90 of magnesium sulphate; and consequently there might be no precipitate, or one redissolved by the liquid, should the proportion of lime be very small. (*Journ. de Pharm.*, 4e sér., iii. 216.) As magnesia is completely dissolved by hydrochloric acid, silica and other impurities insoluble in that acid would be left behind. Alumina is indicated by the production of a precipitate when ammonia is added in excess to a solution of fifty grains of magnesia in a fluidounce of hydrochloric acid. If the magnesia contain a soluble sulphate or carbonate, barium chloride will reveal it by producing a precipitate with water digested on the magnesia. Rochelle salt has been found as an impurity in magnesia, probably as the result of accident. (*A. J. P.*, Jan. 1873.)

Medical Properties and Uses. Magnesia is antacid and laxative, and is much used, under the name of *calcined magnesia*, in *dyspepsia*, *sick headache*, *gout*, and other complaints attended with sour stomach and constipation. It is also a favorite remedy in the complaints of children, in which acidity of the primæ viæ is often a prominent symptom. Its antacid properties render it useful in *gravel* attended with an excessive secretion of uric acid. Its advantages over magnesium carbonate are that it may be given in a smaller dose and does not occasion flatulence.* The dose as a laxative is from thirty grains to a drachm (1·95–3·9 Gm.); as an antacid merely, or an antilithic, from ten to thirty grains (0·65–1·95 Gm.) twice a day. When it meets with no acid, it is apt to linger in the stomach or bowels, and may in that case be followed by lemonade. It should be administered in water or milk, and thoroughly triturated so as to render the mixture uniform. If mixed with less than 14 or 15 times its weight of water, and allowed to stand for a day or two, magnesia is apt to form a more or less concrete mass, owing to the production of a hydrate. This change does not take place, or at least takes place much less readily, when magnesia already saturated with moisture is employed instead of that freshly calcined. It has been conjectured that anhydrous magnesia might prove injurious in the stomach by solidifying its liquid contents; and the earth which has become saturated with moisture by exposure to a damp air is preferably recommended. Freshly precipitated magnesium hydrate will serve as an antidote to arsenous acid, though less efficient than ferric hydrate. The experiments of M. Carles have shown that the soluble *magnesium saccharate* is not superior as an antidote for arsenic to simple magnesia. Dr. Ohleyer (*London Lancet*, July, 1873) employs magnesia as a dressing in *ulcers* and *abrasions*, whilst Vergely recommends for *burns* calcined magnesia triturated with milk so as to form a paste, which should be applied thickly several times a day.

MAGNESIA PONDEROSA. U. S., Br. Heavy Magnesia.

MgO; 40·26. (MĂG-NĒ'ŞI-Ą PŎN-DĘ-RŌ'SĄ.) MgO; 40.

Heavy Calcined Magnesia; Oxide of Magnesium.

"A white, dense, and very fine powder, which should conform to the reactions and tests given under *Magnesia*. It differs, however, from the latter in not readily uniting with water to form a gelatinous hydrate." *U. S.* "Heavy Magnesium Oxide, MgO, is prepared by exposing Heavy Magnesium Carbonate to a dull red heat." *Br.*

This was directed, in the British Pharmacopœia 1885, to be prepared precisely in the same manner as light magnesia, using, however, the heavy carbonate (Heavy Magnesium Carbonate, *Br.*). It is described by the Br. Ph. 1898 as "A white powder, insoluble in *water*, but readily dissolved by acids, the solution affording the reactions characteristic of magnesium. It should yield no characteristic reaction with the tests for iron, aluminium, calcium, or carbonates, and only the slightest reactions with the tests for chlorides or sulphates. When heated to dull redness it should lose little or no weight." The two varieties of light and heavy magnesia differ only in their weight in the same bulk, the volumes corresponding to the same weight being to each other in the ratio of three and one-half to one. (See *Magnesia*, above.)

* *Trochisci Magnesiæ.* U. S. 1880. *Troches of Magnesia.* "Magnesia, *three hundred grains* (19·50 Gm.); Nutmeg, in fine powder, *fifteen grains* (1·00 Gm.); Sugar, in fine powder, *nine hundred grains* (58·50 Gm.): Mucilage of Tragacanth, *a sufficient quantity*, To make *one hundred troches*. Rub the Magnesia and powder together until they are thoroughly mixed; then, with Mucilage of Tragacanth, form a mass, to be divided into *one hundred troches*." *U. S.* These each contain three grains (0·20 Gm.) of magnesia, and are useful in *acidity of the stomach*, especially when attended with constipation.

MAGNESII CARBONAS. U. S. (Br.) Magnesium Carbonate.

(MĂG-NĒ'ŞI-Ī CĂR'BŌ-NĂS.)

Approximately $(MgCO_3)_4.Mg(OH)_2 + 5H_2O$; 484·62. $(MgCO_3)_4.Mg(HO)_2.5H_2O$; 484.

Carbonate of Magnesia; Magnesia Carbonica, *P. G.;* Magnesia Hydrico-carbonica, Carbonas Magnesicus, Magnesia Alba, *Lat.;* Carbonate de Magnésie, Magnésie blanche, *Fr.;* Kohlensaure Magnesia, Weisse Magnesia, *G.;* Carbonato di Magnesia, *It.;* Carbonato de Magnesia, *Sp.*

Magnesium Carbonate sometimes occurs as a native mineral known as *magnesite*, the best deposits of which are those of the Grecian Archipelago, though a common variety is found in Chester Co., Pa. That which is sold in commerce is prepared on a large scale by the manufacturer. In the British Pharmacopœia directions are given for preparing it in two forms: that of Magnesii Carbonas Ponderosus, or *Heavy Magnesium Carbonate;* and that of Magnesii Carbonas Levis, or *Light Magnesium Carbonate.* The following are the directions:

1. Magnesii Carbonas Ponderosus. *Heavy Magnesium Carbonate. Br.* "This preparation, $3(MgCO_3),Mg(HO)_2,4H_2O$, may be obtained by the following process. Magnesium Sulphate, 10 *ounces* (Imperial) or 125 grammes; Sodium Carbonate, 12 *ounces* (Imp.) or 150 grammes; Distilled Water, boiling, *a sufficient quantity.* Dissolve the Magnesium Sulphate and the Sodium Carbonate each in a *pint* (Imp. meas.) or two hundred and fifty cubic centimetres of the Distilled Water; mix the solutions, and evaporate to dryness; digest the residue for half an hour with *two pints* (Imp. meas.) or five hundred cubic centimetres of the Distilled Water, and having collected the insoluble matter on a calico filter, wash it repeatedly with the Distilled Water until the washings are free from sulphates; dry the product at a temperature not exceeding 212° F. (100° C.)." *Br.*

This is essentially the old process of the Dublin College for Magnesiæ Carbonas Ponderosum, or *Heavy Carbonate of Magnesia*, and yields a product which is characterized in the British Pharmacopœia as "A white granular powder, which dissolves readily, with effervescence, in the diluted mineral acids, the solutions affording the reactions characteristic of magnesium. 5 grammes calcined at a red heat should be reduced to 2·1 grammes. It should yield no characteristic reaction with the tests for iron, aluminium, or calcium, and only the slightest reactions with the tests for chlorides or sulphates."

2. Magnesii Carbonas Levis. *Light Magnesium Carbonate. Br.* "This preparation, $3(MgCO_3),Mg(HO)_2,4H_2O$, may be obtained by the following process. Magnesium Sulphate, 10 *ounces* (Imperial) or 125 grammes; Sodium Carbonate, 12 *ounces* (Imp.) or 150 grammes; Distilled Water, *a sufficient quantity.* Dissolve the Magnesium Sulphate and the Sodium Carbonate each in *half a gallon* (Imp. meas.) or one litre of cold Distilled Water; mix the two solutions; boil the mixture for fifteen minutes; transfer the precipitate to a calico filter; pour upon it boiling Distilled Water until the washings are free from sulphates; dry at a temperature not exceeding 212° F. (100° C.)." *Br.* The resulting carbonate is characterized in the British Pharmacopœia as "A very light powder, which, when examined under the microscope, is found to consist of amorphous particles with numerous slender prisms intermixed. The other characters and tests are the same as those of Heavy Magnesium Carbonate."

Potassium carbonate is less eligible than sodium carbonate for the preparation of magnesium carbonate. It is difficult to separate the last portions of potassium sulphate from the precipitate, and potassium carbonate usually contains silica, which is thrown down with the magnesia. The consequence is that, when prepared with that salt, magnesium carbonate is liable to be gritty to the touch and to have a saline taste. The following method is said to be pursued by some of the best manufacturers. To a saturated solution of 100 parts of magnesium sulphate, a solution of 125 parts of crystallized sodium carbonate is gradually added, the solutions being constantly stirred. The mixture is heated to ebullition, to complete the precipitation of the magnesia, which is then washed with tepid and finally with cold water, until the washings no longer give a precipitate with barium salts. When sufficiently washed, the carbonate is allowed to drain for one or two days on large linen filters, and is then placed in wooden moulds with a porous bottom of brick or gypsum, and subjected to pressure in order to give it a square and compact form. According to Otto and Gabler, very pure magnesium carbonate is made at Nauheim, Germany. Pattinson's process is used. It depends upon the fact that, on treating calcined dolomite, in the presence of water, with carbonic acid under pressure, the magnesia dissolves as bicarbonate before any of the accompanying lime enters in solution. The calcined and finely powdered mineral is introduced, together with water, into a cylinder with a horizontal axis, and, while it is being kept in constant motion by a stirring apparatus, carbonic acid gas, under a pressure of five to six atmospheres, is forced into it. The resulting solution of magnesium bicarbonate, which is perfectly free from lime, if the process has been properly man-

aged, is then transferred to a vertical cylinder, where it is heated with steam, whereby magnesium carbonate is separated, which is collected, formed into prismatic pieces, and dried. The carbonic acid gas required issues from the earth immediately outside of the factory; and the dolomite is furnished by the quarries of May and Urban, near Dietz and Steelen on the Lahn. (*Arch. d. Pharm.*, Aug. 1880; *N. R.*, Sept. 1881.)

The density of magnesium carbonate is said to depend upon the strength of the solutions from which it is first precipitated, and its fineness and softness to the touch, upon the use of sodium carbonate in its preparation. Much of the magnesium carbonate formerly used in this country was imported from England and Ireland, but that now consumed in the United States is chiefly a home product. The Keasbey & Mattison Company, who are the largest manufacturers of carbonate at the present time (1899), use the process of decomposing calcined dolomite by forcing carbonic acid into its aqueous mixture, and heating this to precipitate the carbonate. When made from bittern, magnesium carbonate is contaminated with calcium carbonate, salts of lime being contained in sea-water; and when it is prepared from magnesite, or from magnesian schist, iron is almost always present. The only way in which these impurities can be avoided is to prepare pure magnesium sulphate by repeated crystallization, and to use a pure sodium carbonate. It is also necessary that the water with which the precipitate is washed should be free from earthy salts, which would be decomposed and contaminate the magnesia. Kippenberger prepares crystallized magnesium carbonate by shaking *freshly* precipitated magnesium carbonate with a solution of potassium bicarbonate at the ordinary temperature; much of the magnesium carbonate dissolves and crystallizes out of the filtered solution upon standing for a day. Sodium bicarbonate may be used instead of the potassium salt, but the crystals are smaller. (*Zeit. f. Anorg. Chem.*, 1894, 177.)

Properties. Magnesium carbonate is inodorous, nearly insipid, perfectly white, smooth to the touch, and nearly insoluble in water, requiring 2493 parts of cold and 9000 parts of hot water for solution. It is decomposed by strong heat, by all the acids, by potassa, soda, lime, barium and strontium oxides, and by acidulous and metallic salts. "Light, white, friable masses, or a light, white powder, without odor, and having a slightly earthy taste; permanent in the air. Almost insoluble in water, to which, however, it imparts a slightly alkaline reaction; insoluble in alcohol, but soluble in dilute acids with active effervescence. When strongly heated, the salt loses water and carbon dioxide, and is converted into magnesia. A filtered solution of the salt in diluted sulphuric acid, when mixed with ammonium chloride test-solution and an excess of ammonia water, yields, with sodium phosphate test-solution, a white, crystalline precipitate. If the salt be boiled with water, the filtered liquid, when evaporated to dryness, should not leave more than a very slight residue. A 2-per-cent. solution of the salt, prepared by the addition of acetic acid, should not be rendered more than slightly opalescent by ammonium oxalate test-solution (limit of *calcium*); nor by barium chloride test-solution (limit of *sulphate*); nor, after the addition of a few drops of nitric acid, by silver nitrate test-solution (limit of *chloride*). If 0·4 Gm. of the salt be dissolved in 5 C.c. of diluted hydrochloric acid, the solution should be colorless, and should not be affected by hydrogen sulphide test-solution, nor, after the addition of an excess of ammonia water, should it be immediately affected by ammonium sulphide test-solution (absence of *metallic impurities*). If 1·0 Gm. of the salt be ignited in a porcelain crucible, the residue should weigh not less than 0·4 Gm." *U. S.* Dr. Pereira states that the *light carbonate*, when examined with the microscope, is seen to consist of an amorphous powder, more or less intermingled with slender prismatic crystals, which appear as if they were eroded or efflorescent; the *heavy carbonate* consists of granules of various sizes, without any traces of the prismatic crystals observed in the former variety.

A solution in carbonic acid water, prepared by passing carbonic acid gas into a reservoir containing magnesium carbonate suspended in water, has been introduced into use as a cathartic and antacid. *Dinneford's Magnesia* is a solution of this nature. According to Dr. Christison, it contains only nine grains of carbonate in the fluidounce, though alleged to contain twice that quantity. Its taste is more disagreeable than that of the undissolved carbonate. A formula for this preparation has been introduced into the British Pharmacopœia, with the name of Liquor Magnesiæ Carbonatis.

Adulterations and Tests. Magnesium carbonate may contain an alkaline carbonate or sulphate, or both, from insufficient washing; also sodium chloride, alumina, and calcium carbonate. If water boiled on it changes turmeric, an alkaline carbonate is indicated. If barium chloride produces a precipitate in the water, the presence of a sulphate or carbonate is shown; and if silver nitrate produces precipitation, a chloride is indicated. When dissolved in an ex-

cess of hydrochloric acid, an excess of ammonia will throw down alumina, which is almost always present in minute quantity; and ammonium oxalate, afterwards added to the filtered chloride solution, will throw down calcium oxalate if lime be present. When the same solution, nearly neutralized, is rendered blue by potassium ferrocyanide, iron is indicated.

Composition. According to Berzelius, magnesium carbonate of commerce (*magnesia alba*) is a combination of three mols. of magnesium carbonate with one of magnesium hydrate. According to Phillips, whose analysis agrees with a subsequent one by Fownes, four mols. of the carbonate are combined with one of the hydrate and four of water. (*P. J. Tr.*, iii. 480.) The formula given by the British Pharmacopœia is $3MgCO_3 + Mg(OH)_2 + 4H_2O$; in other words, a combination of three mols. of magnesium carbonate, two of magnesium hydrate, and four of water; while the U. S. Pharmacopœia of 1890 makes it $4MgCo_3 + Mg(OH)_2 + 5H_2O$. The composition of this salt varies with the mode of preparation.

Medical Properties and Uses. Magnesium carbonate is antacid, and, by combining with acid in the stomach, becomes generally cathartic. When it undergoes no change in the alimentary canal it produces no purgative effect. Under these circumstances it may usually be made to operate by following it with draughts of lemonade. It is useful in all cases which require a laxative antacid; and, though apt to produce flatulence in consequence of the extrication of its carbonic acid in the stomach and bowels, and therefore in ordinary cases inferior to calcined magnesia, it sometimes operates favorably, in consequence of this very property, in *sick stomach* attended with acidity. Magnesium carbonate is also an excellent antilithic when uric acid is secreted in excess. The dose is from half a drachm to two drachms (1·95–7·8 Gm.), which may be given in water or milk. In order that it may be accurately diffused through water, it should be previously rubbed down with syrup or ginger syrup. Magnesium carbonate is a useful agent for diffusing camphor and the volatile oils through water, in preparing several of the medicated waters, and is also used with a similar purpose as a diffusing agent in preparing syrups or elixirs.

MAGNESII CITRAS EFFERVESCENS. U. S. Effervescent Magnesium Citrate.

(MĂG-NĒ'ŞI-Ī CĪ'TRĂS ĔF-FĘR-VĔS'CĘNŞ.)

Magnesii Citras Granulatus, *U. S.* 1880; Granulated Citrate of Magnesium.

"Magnesium Carbonate, *ten grammes* [or 154 grains]; Citric Acid, *forty-six grammes* [or 1 ounce av., 272 grains]; Sodium Bicarbonate, *thirty-four grammes* [or 1 ounce av., 87 grains]; Sugar, in fine powder, *eight grammes* [or 123 grains]; Alcohol, Distilled Water, each, *a sufficient quantity*. Mix the Magnesium Carbonate intimately with *thirty grammes* [or 1 ounce av., 25 grains] of Citric Acid and *four cubic centimeters* [or 65 minims] of Distilled Water, so as to form a thick paste. Dry this at a temperature not exceeding 30° C. (86° F.), and reduce it to a fine powder. Then mix it intimately with the Sugar, the Sodium Bicarbonate, and the remainder of the Citric Acid previously reduced to a very fine powder. Dampen the powder with a sufficient quantity of Alcohol, so as to form a mass, and rub it through a No. 6 tinned-iron sieve. Then dry it, and reduce it to a coarse, granular powder. Keep the product in well-closed vessels." *U. S.*

This is an official salt, intended to furnish an agreeable, effervescent drink. It is very important to obey the direction to keep it in well-closed bottles, for if permitted access of air the moisture would soon cause the acid to act upon the carbonates and liberate the carbonic acid gas gradually, and thus destroy the effervescent character of the preparation, its principal recommendation. Large quantities of so-called effervescent magnesium citrate are sold in this country and in England which contain no magnesium citrate at all, being effervescent salts of sodium tartrate.* W. L. Scoville analyzed three commercial specimens. (*Pharm. Record*, 1892, 267.) One English brand contained anhydrous magnesium sulphate, Rochelle salt, sodium bicarbonate, tartaric acid, and sugar; another English salt contained magnesium sulphate, sodium sulphate, potassium carbonate, sodium bicarbonate, tartaric acid, and sugar; a Philadelphia preparation contained magnesium carbonate, citric and tartaric acids, sodium and potassium bicarbonates, and sugar.

Properties. "A white, coarsely granular salt, without odor, and having a mildly acidulous, refreshing taste. Deliquescent on exposure to the air. Soluble, with copious efferves-

* *Magnesium acetate* has been proposed as a substitute for magnesium citrate. It is very soluble in alcohol and also in water, and is said to act well as a saline purgative, but it is open to the objection of having an empyreumatic taste. (See *A. J. P.*, Sept. 1884.)

cence, in 2 parts of water at 15° C. (59° F.), and very soluble in boiling water; almost insoluble in alcohol. The aqueous solution (1 in 20) has an acid reaction, and, after the addition of ammonium chloride test-solution and a slight excess of ammonia water, it yields, with sodium phosphate test-solution, a white, crystalline precipitate. If to another portion of the aqueous solution a little calcium chloride test-solution be added, and then a slight excess of ammonia water, the filtered liquid will deposit a white precipitate on boiling. A saturated aqueous solution of the salt, when mixed with potassium acetate test-solution and a small quantity of acetic acid, should not yield a white, crystalline precipitate (absence of *tartrate*)." *U. S.*

Medical Properties. The medical properties are those of its solution, except that, as it does not contain a large excess of acid, it is less pleasant to the palate, but may in some cases suit the stomach better. (See *Liquor Magnesii Citratis.*) It has also the advantage of portability. The dose is from one to three teaspoonfuls.

MAGNESII SULPHAS. U. S., Br. Magnesium Sulphate. [Epsom Salt.]

$MgSO_4 + 7H_2O$; 245·84. (MĂG-NĒ'ŞĮ-Ī SŬL'PHĂS.) $MgSO_4.7H_2O$; 246.

"Magnesium Sulphate, $MgSO_4,7H_2O$, may be prepared by the interaction of the native magnesium carbonates and diluted sulphuric acid; or by purifying the native sulphate." *Br.*

Sulphate of Magnesia; Magnesia Sulfurica, *P. G.;* Sal Amarum, Sal Epsomense, Sal Anglicum, Sal Sedlicense, Sulfas Magnesicus; Sulfate de Magnésie, Sel d'Epsom, Sel de Sedlitz, Sel amer, *Fr.;* Schwefelsaure Magnesia, Bittersalz, *G.;* Solfato di Magnesia, *It.;* Sulfato de Magnesia, *Sp.*

Magnesium Sulphate is a constituent of sea-water, and of some saline springs. It also occurs native, either crystallized in slender, prismatic, adhering crystals, or as an efflorescence on certain rocks and soils which contain magnesia and a sulphate or sulphide. In the United States it is found in the great caves so numerous to the west of the Alleghany Mountains. In one of these caves, near Corydon in Indiana, it formed a stratum on the bottom several inches deep, or appeared in masses sometimes weighing ten pounds, or disseminated in the earth of the cavern, one bushel of which yielded from four to twenty-five pounds of the sulphate. It also appeared on the walls of the cavern, and, if it was removed, acicular crystals again appeared in a few weeks. (*Cleveland.*)

Under the name of *kieserite*, a mineral is obtained from the saline deposits at Stassfurt, in Germany, which consists chiefly of impure magnesium sulphate. The production of kieserite for the year 1896 was 25,198 tons, and for the year 1897, 25,882 tons. It is used as a source for preparing magnesium sulphate, and is exported from Germany.

Magnesium sulphate was originally procured by evaporating the waters of saline springs at Epsom, in England. Dr. Grew prepared it in this manner in 1675. It was afterwards discovered that the brine remaining after the crystallization of common salt from sea-water furnished by careful evaporation precisely the same salt; and, as this was a much cheaper product, it superseded the former. The residual brine, or bittern, consists of magnesium sulphate and magnesium and calcium chlorides. As the magnesium sulphate crystallizes first, it may with proper care be obtained nearly pure, although most frequently the salt prepared in this way is deliquescent from the presence of magnesium chloride. It may be freed from this impurity by washing the crystals with their own saturated solution. It was from this source that the greater part of the Epsom salt of commerce was long obtained in Europe. The salt-works of New England supplied our own markets with an impure and deliquescent sulphate. With the improvements of chemistry, other and better processes have been adopted. In the neighborhood of Genoa and Nice, magnesium sulphate is prepared in large quantities from a schistose rock containing magnesia and iron sulphide. The mineral is roasted, and exposed in heaps for some months to the action of air and water. It is then lixiviated, the ferrous sulphate decomposed by lime water, and the salt obtained pure by repeated solution and crystallization.

William Henry, of Manchester, whose calcined magnesia has become famous throughout the world, took out a patent for a mode of preparing magnesia and its salts from the double magnesium and calcium carbonate,—the *dolomite* of mineralogists. His process was to drive off the carbonic acid by heat, and to convert the remaining earth into hydrates. He treated these with a sufficient quantity of hydrochloric acid to dissolve out the lime, and then converted the magnesia into a sulphate either by sulphuric acid or by ferrous sulphate.

The salt is extensively manufactured in Baltimore and Philadelphia from a silicious magnesium hydrate. This mineral occurs in veins in the serpentine and other magnesian rocks which abound in the neighborhood of Baltimore and in the southern counties of Pennsylvania. The advantage which it possesses over the dolomite, in the preparation of this salt, is the almost

entire absence of lime, owing to which there is little or no waste of acid, and the operation is much simplified. The mineral is reduced to a fine powder and saturated with sulphuric acid. The mass is then dried and calcined at a red heat, in order to convert any ferrous sulphate which may be present into ferric oxide. It is then dissolved in water, and calcium sulphide added to separate any remaining portion of iron. The salt is crystallized and dissolved a third time, in order to purify it. The sulphate prepared by this process is generally very pure and clean, although it sometimes contains a trace of ferrous sulphate. A very pure magnesium sulphate free from chloride is obtained as a side product in the manufacture of carbon dioxide from magnesite when sulphuric acid is used to decompose the carbonate. This industry has assumed large proportions because of the demand for liquefied carbon dioxide in the manufacture of aerated and effervescing mineral waters.

Properties. Magnesium sulphate is in "small, colorless, rhombic prisms, or acicular crystals, without odor, and having a cooling, saline, and bitter taste; slowly efflorescent in dry air. Soluble in 1·5 parts of water at 15° C. (59° F.), and in 0·7 part of boiling water; insoluble in alcohol. When heated to 52° C. (125·6° F.), the salt loses 1 molecule of water, and is converted into a white powder. At about 132° C. (269·6° F.) it still retains 1 molecule of water, and at a temperature of 200° to 238° C. (392° to 460·4° F.) it is rendered anhydrous. The aqueous solution is neutral to litmus paper. When mixed with ammonium chloride test-solution and ammonia water, it yields, with sodium phosphate test-solution, a white, crystalline precipitate. With barium chloride test-solution it yields a white precipitate insoluble in nitric acid. When a small portion of the salt is introduced, on a clean platinum wire, into a non-luminous flame, it should not impart to the latter a persistent yellow color (limit of *sodium*). A 5-per-cent. aqueous solution of the salt should not be affected by hydrogen sulphide test-solution (absence of *metallic impurities*), nor produce more than a slight opalescence with silver nitrate test-solution (limit of *chloride*); nor should 20 C.c. of the same solution give any coloration or precipitate on the addition of 0·5 C.c. of potassium ferrocyanide test-solution (absence of *iron*, *zinc*, or *copper*). If 1 Gm. of the powdered salt be shaken with 3 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), a small piece of pure tin-foil added, and the test-tube then set aside, no coloration should appear within one hour (limit of *arsenic*)." *U. S.* "Soluble in 1 part of cold *water*, and possessing a bitter taste. It affords the reactions characteristic of magnesium and of sulphates. 0·5 gramme dissolved in 250 cubic centimetres of *water*, when set aside for twelve hours with a mixture of *solution of ammonia*, *solution of ammonium chloride*, and *solution of sodium phosphate*, yields a precipitate which, when thoroughly washed, dried, and heated to redness, weighs 0·22 gramme. Magnesium Sulphate should yield no characteristic reaction with the tests for iron, aluminium, zinc, calcium, sodium, potassium, ammonium, or nitrates, and only the slightest reactions with the tests for chlorides." *Br.* It usually occurs in small acicular crystals, which are produced by agitating the solution while crystallizing. It slowly effloresces in the air. At 32° F. 100 parts of water dissolve 25·76 parts of the anhydrous salt, and for every increased degree 0·8597 part additional is taken up. The crystals contain 54·22 per cent. of water of crystallization, dissolve in their own weight of water at 60° F. and in three-fourths of their weight at 212° F., melt in their water of crystallization, and at a high temperature fuse into an enamel.

Magnesium sulphate is completely decomposed by potassa, soda, and their carbonates; by lime, barium and strontium oxides, and their soluble salts. Ammonia partially decomposes it, and forms with the remainder a double sulphate. Potassium and sodium bicarbonates do not decompose it, except by the aid of heat. An aqueous solution of 100 grains of the salt should yield, when completely decomposed by a boiling solution of sodium carbonate, 34 grains of dry magnesium carbonate, and, according to the British Pharmacopœia, 16·26 grains of the carbonate after having been well washed, dried, and heated to redness. If the dry precipitate be less, the specimen tested is not all magnesium sulphate, and probably contains sodium sulphate. An economical use which has been recommended of magnesium sulphate is the addition of a strong solution to ordinary whitewash, whereby a beautiful whiteness may be given to walls and ceilings. A little of it, moreover, added to starch considerably increases its stiffening properties, and at the same time in some degree resists the action of fire. (*Chem. News*, April, 1867.)

Medical Properties and Uses. Magnesium sulphate is an active but safe cathartic, operating with little pain or nausea, and producing watery stools. It is more acceptable to the stomach than most medicines of its class, and will often be retained when others are rejected. Like many of the other neutral salts, it is refrigerant, and may be made to act as a diuretic by

keeping the skin cool and walking about after it has been taken. It is well adapted to the treatment of *fevers* and *inflammatory affections*. It is also useful in *colic* and *obstinate constipation*, and may be employed in most cases which require the use of a cathartic without being attended with debility or relaxation of the stomach and bowels. The medium dose is an ounce (31·1 Gm.); but advantage often results from its administration in divided doses frequently repeated. It is often given in combination with other medicines, especially with senna, the griping effect of which it tends to obviate. The most agreeable form for administering the salt, and that in which it usually agrees best with the stomach, is a solution in carbonic acid water with lemon syrup. By Dr. Henry, of Dublin, it is highly recommended in connection with diluted sulphuric acid. To seven ounces of a saturated aqueous solution of the salt he adds an ounce of the diluted sulphuric acid of the Pharmacopœias, and gives a tablespoonful of the mixture for a dose, in a wineglassful of water.*

The experiments of Recke, Hay, and Henry Curci show that when injected into the veins magnesium sulphate acts as a violent poison, producing at first increase of the blood-pressure with slowing of the pulse, and finally lowering of the blood-pressure, quickening of the pulse, and death sometimes by failure of respiration, at other times by cardiac arrest. As Christison reported the case of a boy ten years old who was said to have been killed by two ounces of the salt without the induction of purgation, it is possible that under some circumstances very large amounts of magnesium sulphate given by the mouth may be sufficiently absorbed to produce poisonous effects.

Many years ago the hypodermic use of magnesium sulphate as a purgative was reported upon favorably by clinicians, but certainly this use of the remedy failed to become at all general. Recently the method has been recommended by Fincke, by Rohé, by Wade, and by James Wood, who assert that the hypodermic injection of from one and a half to four and a half grains of the magnesium sulphate will produce watery stools in the majority of cases; but no purgation follows in from twenty to forty per cent. of the cases. The effects of the injection of large doses into the lower animals must cause some hesitation in the use of large amounts of the magnesium sulphate hypodermically. Rectal injections of from one to three ounces of the saturated solution of the magnesium sulphate often act very favorably, but are somewhat uncertain.

MAGNESII SULPHAS EFFERVESCENS. Br. Effervescent Magnesium Sulphate.

(MĂG-NĒ'ŞĮ-Ī SŬL'PHĂS ĔF-FĘR-VĔS'CĘNŞ.)

Magnesiæ Sulphas Effervescens; Effervescent Sulphate of Magnesia; Effervescent Epsom Salt.

"Magnesium Sulphate, in crystals, 50 *ounces* (Imperial) or 500 grammes; Sodium Bicarbonate, in powder, 36 *ounces* (Imp.) or 360 grammes; Tartaric Acid, in powder, 19 *ounces* (Imp.) or 190 grammes; Citric Acid, in powder, 12½ *ounces* (Imp.) or 125 grammes; Refined Sugar, in powder, 10½ *ounces* (Imp.) or 105 grammes. Dry the Magnesium Sulphate at about 130° F. (54·4° C.) until it has lost twenty-three per cent. of its weight; powder the product; mix it with the Refined Sugar and then with the other ingredients. Place the mixture in a dish or pan of suitable form heated to between 200° and 220° F. (93·3° and 104·4° C.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54·4° C.). The product should weigh about 100 *ounces* (Imp.) or 1000 grammes." *Br.*

This is a British official effervescent salt, intended to furnish a less disagreeable form of administering Epsom salt. The dose is from one-quarter to one ounce (7·77–31·1 Gm.).

MANGANI DIOXIDUM. U. S. (Br.) Manganese Dioxide. [Mangani Oxidum Nigrum, Pharm. 1880. Black Oxide of Manganese.]

(MĂN'GĄ-NĪ DĪ-ŎX'Į-DŬM.)

"Native crude Manganese Dioxide, containing at least 66 per cent. of the pure Dioxide [$MnO_2 = 86·72$]." *U. S.*

Manganese Peroxide, *Br.* 1898, Appendix; Manganum Hyperoxydatum, *P. G.;* Oxydum Manganicum; Manganese, Peroxide of Manganese, Deutoxide of Manganese, Black Oxide of Manganese, Pyrolusite; Oxide noir de Manganèse, *Fr.;* Braunstein, *G.;* Manganese, *It., Sp.*

* It is said that a solution of an ounce of the salt in about a pint of water, boiled for three minutes with a grain and a half of tannic acid, or with two or three drachms of roasted coffee, is entirely deprived of bitterness. The liquid prepared with coffee should be strained, and may be sweetened with sugar. (Combes, *Journ. de Pharm.*, 3e sér., xii. 110.)

The official oxide of manganese is the dioxide of the metal manganese. *Metallic manganese* was discovered by Scheele and Gahn in 1774, and is obtained from the native black oxide by intense ignition with charcoal. As obtained by C. Brunner, by decomposing sodium fluoride, manganese is brittle, grayish white, and very hard, being capable of cutting glass and scratching the best tempered steel. It is susceptible of the most perfect polish, and decomposes water at a boiling temperature. Its sp. gr. is about 8·0, or, according to more recent determinations, 7·2. Deville obtained the metal by heating the black oxide in excess with charcoal, in a lime crucible. The metal thus obtained is more refractory than iron, while that procured by Brunner fused at the same heat as white cast iron. Greene and Wahl have lately succeeded in getting the metal in large masses by the reduction of the ores with the aid of silicon, which they add in the form of an iron silicide. The atomic weight of manganese is 54·8. With oxygen it forms five and possibly seven compounds: MnO, Mn_2O_3, Mn_3O_4, MnO_2, and Mn_2O_7. The *monoxide* is of a light green color, and is the oxide present in or corresponding to manganous salts. The *sesquioxide* is black or dark brown, when in the hydrated state; the magnetic oxide, Mn_3O_4, is red; the dioxide is black; and the permanganic oxide, Mn_2O_7, is, when in the free state, a very unstable dark reddish-brown liquid. The monoxide is a stable base, the sesquioxide is feebly basic, and the dioxide when acted upon by acids yields manganous salts, while oxygen is evolved. The highest oxide is acid-forming, yielding permanganic acid, $HMnO_4$, the salts of which are known as permanganates. (See *Potassii Permanganas.*) There exists also an acid, H_2MnO_4 (manganic), of which the salts formed are called manganates. The oxide corresponding is not known, however. Metallic manganese is an occasional constituent of organic matter. It has been detected in minute quantity in bone, hair, brain, epidermis, gastric juice, bile, urine, and pus, and has been found by Millon and others in the blood. M. Glénard, of Lyons, denies that it is a normal constituent of the blood, although sometimes present; but the evidence of numerous experimenters shows that it generally exists in that fluid; and when not detected it may be because the quantity present is too minute to be easily discovered.* According to Mr. E. Davy, caustic potassa, dissolved in an equal weight of water, forms a delicate test for manganese, not obscured by the presence of other metals. The smallest portion of matter suspected to contain the metal, being finely pulverized or in solution, is placed upon a slip of silver foil, and a drop of the test added. Upon evaporating to dryness with a spirit-lamp, and raising the heat, the characteristic green potassium manganate will appear on the foil. (*Chem. Gaz.*, March 15, 1854.) Manganese is a constituent of all arable land, and is found in the ashes of most of the vegetables which form the food of man and the inferior animals. In the mineral kingdom it occurs sometimes as silicate (rhodonite) or carbonate (diallogite), and very abundantly as the black oxide, or dioxide, called *pyrolusite.* It is the latter mineral which constitutes the official oxide.

Properties. Manganese dioxide, as it occurs in nature, is very diversified in its appearance. Its sp. gr. varies from 4·7 to 4·9. It is found sometimes in brilliant needle-shaped crystals, often in compact masses having the metallic lustre, but far more frequently in the form of a dull earthy-looking substance of a black or brown color. It is purest when crystallized. As it occurs in commerce, it is usually in the form of a black powder, insoluble in water, and containing more or less oxidized iron, calcium carbonate, barium sulphate, and earthy matter. Iron, which is rarely absent, is detected by the production of a greenish or blue tint on the addition of potassium ferrocyanide to its chloride solution. When exposed to a red heat it yields a portion of its oxygen, and is reduced to the state of sesquioxide. Hence its use in obtaining that gas. Good samples, after being dried, lose, when heated to whiteness, 12 per cent. of oxygen. It is distinguished from antimony sulphide by its infusibility, and by causing the evolution of chlorine on being heated with hydrochloric acid. When of a brown color, it is not of good quality.

The U. S. Pharmacopœia describes it as "a heavy, grayish-black, more or less gritty powder, without odor or taste; permanent in the air. Insoluble in water or alcohol. It is not affected by cold, concentrated sulphuric acid, but when heated with the latter it is converted into manganous sulphate, with the evolution of oxygen. When heated with hydrochloric acid, it is converted into manganous chloride, with the development of chlorine. At a red heat the Dioxide gives off oxygen gas, and is converted into reddish-brown manganoso-manganic oxide [Mn_3O_4]. On intimately mixing 1 part of the Dioxide with 1 part of potassium hydrate and 1 part of potassium chlorate, introducing the mass into a crucible, moistening with water, drying, and igniting, a dark fused mass is obtained, which yields, with water, a green solution,

* For an elaborate article on the absorption of manganese, see *Arch f. Exper. Path. und Pharm.*, xviii. p. 129.

changing to purplish-red on being boiled, or on the addition of diluted sulphuric acid. If a portion of the Dioxide be strongly heated in a dry test-tube, no combustion should ensue, nor should any carbon dioxide be evolved (absence of *organic impurities*). If to another portion of the Dioxide, contained in a test-tube, a small quantity of diluted hydrochloric acid be added, no odor of hydrogen sulphide should be developed, nor should a strip of paper moistened with lead acetate test-solution, and suspended over the mixture, become blackened (absence of *metallic sulphides*). After the mixture of the Dioxide with hydrochloric acid has been raised to boiling and filtered, the filtered liquid should not give, with hydrogen sulphide test-solution, an orange-colored precipitate (absence of *antimony sulphide*). If 1 Gm. of the finely-powdered Dioxide, contained in a small, long-necked flask, be mixed with 5 C.c. of water, then 4·22 Gm. of ferrous sulphate, in clear crystals, added, and subsequently 5 C.c. of hydrochloric acid, the mixture digested for about fifteen minutes at a gentle heat, and finally heated to boiling, the cooled filtrate, when immediately tested with freshly prepared potassium ferricyanide test-solution, should not acquire a blue color (presence of at least 66 per cent. of pure *Manganese Dioxide*)."

But few mines of manganese dioxide exist; though the metal itself is very generally diffused throughout the mineral kingdom. It occurs most abundantly in the Russian Caucasus, which furnishes nearly half of the annual production of the world, in Chili, Cuba, Great Britain, Turkey, and Australia. In the United States it occurs in largest amount at Crimora, Va., Cartersville, Ga., and Batesville, Ark.; other isolated localities exist in California, Utah, Alabama, and Tennessee. The amount of manganese ore mined in the United States in 1896 was 162,526 tons, valued at $339,083, and in 1897, 156,787 tons, valued at $332,700. These figures include, however, not only the high grade manganese ores and the franklinite residuum of New Jersey, but the low grade manganiferous iron ores of Lake Superior, the last forming the largest part of the total. These two classes last mentioned make all but about 20,000 tons of the total. (*Mineral Industry.*) Besides these sources, the mineral is received from Germany and Russia, and in smaller amount from New Brunswick and Brazil. It comes packed in casks or barrels, generally in lumps and coarse powder, just as it is dug out of the mines; though occasionally it is received from England ready pulverized. It is a good rule to buy it unpowdered, as its quality can be better judged of in that state. A dark shining crystalline appearance is an indication of good quality, although an assay will alone determine its quality with certainty.

Medical Properties and Uses. Manganese dioxide is deemed tonic and alterative. When slowly introduced into the system, as happens to those engaged in grinding the mineral, it acts, according to Dr. Coupar, of Glasgow, as a cumulative poison, inducing a disease which begins with a staggering gait and ends in paraplegia. It has been used in *syphilis*, *chlorosis*, *scurvy*, and various *skin diseases*, especially *itch* and *porrigo*. It has been employed, in a purified state, with alleged great advantage by Dr. Arthur Leared, in *stomachic pains* of a purely nervous character, such as are apt to come on after eating. He has also found it useful in *pyrosis*, and in other irritable states of the stomach which are purely functional. It has the advantage over the preparations of bismuth, in these cases, that it does not constipate. (*Glasgow Med. Journ.*, Jan. 1865, p. 79.) The dose is from three to twenty grains (0·20–1·3 Gm.) three times a day, given in the form of pill. Dr. Leared gave ten grains (0·65 Gm.) of the powder three times a day. For external use, an ointment may be made of one or two drachms of the oxide to an ounce of lard. The sulphate is official. For other compounds of manganese, see PART II.; also *Syrupus Ferri et Mangani Iodidi*, National Formulary.

This oxide is used in the arts for obtaining chlorine in the manufacture of bleaching powder, for giving a black glazing to pottery, and for freeing glass from the color which it derives from iron. In the laboratory it is employed to obtain oxygen and chlorine, and to form the salts of manganese. In pharmacy it is used for liberating chlorine from hydrochloric acid and from common salt, and iodine from sodium iodide contained in kelp.

MANGANI SULPHAS. U. S. Manganese Sulphate. [Manganous Sulphate.]

$MnSO_4 + 4H_2O$; 222·46. (MĂN'GĄ-NĪ SŬL'PHĂS.) $MnSO_4.4H_2O$; 222.

"Manganese Sulphate should be kept in well-stoppered bottles." *U. S.*

Manganesii Sulphas, *U. S.* 1870; Manganum Sulphuricum, Sulfas Manganosus; Manganous Sulphate; Sulfate de Manganèse, Sulfate manganeux, *Fr.*; Schwefelsaures Manganoxydul, *G.*

This salt may be prepared by heating the native black oxide with concentrated sulphuric acid. Oxygen is thereby evolved, and the sulphate is formed. The product, when exhausted

by water, furnishes a solution of the salt which must be heated nearly to the boiling point, and treated with manganese carbonate, added by small portions at a time, which will precipitate any iron present, and change the color of the liquid from a dark red to a pale rose tint. The liquid is then filtered, evaporated to the consistence of a thin syrup, and set aside to crystallize. Prof. C. Lewis Diehl has obtained by means of the following process an abundant product of the pure salt. A mixture of 5 parts of black manganese oxide and 0·75 part of coarsely powdered charcoal is exposed to a red heat, in a covered crucible, until all the charcoal is consumed. The contents of the crucible, after cooling, are put into a porcelain dish, and treated with 6·5 parts of sulphuric acid. The whole is then evaporated to dryness, and the residue, being returned to the crucible, is again heated to redness. When cool, the mass is rubbed to powder if necessary, and treated twice with eight parts of boiling water; and the liquors, having been mixed, are filtered, evaporated till a pellicle appears, and set aside to crystallize. It is important that the liquid should be removed from the sand-bath as soon as the pellicle begins to form; as, if the heat be continued longer, an insoluble sulphate will be deposited. If the black manganese oxide employed be of good quality, a pure sulphate will be obtained, any salt of iron or copper present being rendered insoluble by the heat. (*A. J. P.*, 1867.) Laster's process is as follows. "Take of Black Oxide of Manganese 40 parts, Commercial Hydrochloric Acid 200 parts. Dissolve the black oxide in the acid beneath a chimney-flue, and, when solution is complete, and chlorine no longer evolved, mix very gradually 53 parts of sulphuric acid with the reddish liquid; continue the evaporation beneath the flue until acid vapor is no longer driven off, and the mass becomes dry. Dissolve this mass in 350 parts of water heated to the boiling point. Treat the solution with manganese carbonate until it becomes rose-red, filter or decant, evaporate and crystallize." (*A. J. P.*, 1868.) Mr. F. Mahla, of Chicago, proposes to utilize chlorine residues. He takes the liquid remaining in the retort after the preparation of chlorine, adds to it sodium carbonate sufficient to precipitate all the metallic oxides, or at least to cause a slight alkalinity, collects the precipitate thus produced on a muslin filter, and washes it with pure water, until the filtrate no longer produces an obvious reaction with silver nitrate. Three-fourths of the moist mass are removed from the filter to an evaporating dish, and sufficient dilute sulphuric acid is added to dissolve it completely. The solution is heated nearly to the boiling point, and the remaining fourth of the mass from the filter is gradually added to it, until the liquid, after being filtered, is no longer blackened by tannic acid. The whole solution is then filtered, and the filtrate, with the waters, after washing, is evaporated to crystallization. The first crop of crystals is sometimes contaminated with calcium sulphate, from the calcium carbonate in the commercial black oxide employed in the process. To separate this impurity, evaporate to dryness, redissolve the residue in a little water, which leaves the calcium sulphate undissolved; and the pure solution of manganese sulphate is obtained by filtration. (*A. J. P.*, 1869.) Mr. Edo Claassen adds alcohol to the concentrated solution to promote crystallization. (*Pharm. Rundschau*, 1887.)

Properties. Manganese sulphate has the formula $MnSO_4$, in which the dyad metal manganese replaces the H_2 of H_2SO_4. From its aqueous solution it crystallizes in rhombic prisms, which contain variable proportions of water of crystallization according to the temperature of the solution and other circumstances. Obtained by evaporation at a gentle heat, they contain four mols. of water; between 45° and 68°, five mols.; under 42°, seven mols.; and a concentrated solution, mixed with sulphuric acid, and evaporated, yields granular crystals with one mol. Heated to 240°, these crystals lose three mols. of water, and at a red heat become anhydrous. (*Brande and Taylor.*) The crystals usually have a pale-rose or pink color. The salt has an astringent and bitterish taste. It is very soluble in water; but its solubility varies with its water of crystallization. When anhydrous, it is dissolved by two parts of water at 15·5° C. (60° F.), and in its own weight at 100° C. (212° F.). If carelessly prepared, it is apt to contain copper and arsenic, as well as iron. As it is the source of nearly all the preparations of manganese, it is of importance that it should be pure. Hence the sulphate, as first obtained, should be calcined at a low red heat at least twice, to render the contaminating metals insoluble, and then tested in solution, to be sure of its purity. According to M. A. Görgeu, copper and iron, as well as nickel and cobalt, are completely precipitated by manganese sulphide. In applying this reagent, the impure solution is shaken for about a quarter of an hour with the sulphide, and then boiled for a few minutes. (*Chem. Gaz.*, July 1, 1853, p. 249.) The description of it in the U. S. Pharmacopœia is as follows. "Colorless, or pale rose-colored, transparent, tetragonal prisms (crystallized at a temperature between 20° and 30° C. (68°–86° F.), and containing 4 molecules, or 32·29 per cent., of water of crystallization), odorless, and

having a slightly bitter and astringent taste. Slightly efflorescent in dry air. Soluble in 0·8 part of water at 15° C. (59° F.), and in 1 part of boiling water; insoluble in alcohol. The aqueous solution is neutral or very slightly acid to litmus paper, and yields with ammonium sulphide test-solution a flesh-colored precipitate soluble in dilute acids; with potassium ferrocyanide test-solution, a reddish-white precipitate; and with potassium ferricyanide test-solution, a brown precipitate. With barium chloride test-solution it yields a white precipitate insoluble in hydrochloric acid. If a fragment of the salt be mixed with a little sodium hydrate test-solution, and the mixture then dried and fused, it will yield a dark-green mass, dissolving in water with a green color. A 5-per-cent. aqueous solution of the salt, after being heated with a few drops of hydrochloric acid and a little chlorine water, should not be colored red by potassium sulphocyanate test-solution (absence of *iron*), and should not be affected by hydrogen sulphide test-solution (absence of *copper* or *arsenic*). If the manganese be completely precipitated from an aqueous solution of the salt by ammonium carbonate test-solution, the filtrate, on evaporation and gentle ignition, should leave no residue (absence of *salts of the alkalies*, or of *magnesium*). A solution of 1 Gm., each, of the salt, and of sodium acetate, in 10 C.c. of water, to which a few drops of acetic acid are added, should not be affected by hydrogen sulphide test-solution (absence of *zinc*). If 1 Gm. of the salt be gently ignited, in a porcelain crucible, it should lose not more than 0·323 Gm. in weight (distinction from *Manganese Sulphate containing a larger amount of water of crystallization*)." *U. S.*

Medical Properties and Uses. C. G. Gmelin found manganese sulphate to produce an extraordinary secretion of bile when given to the inferior animals, and its effects as a cholagogue have been observed in man. According to the late Thomas Thomson, of Glasgow, it resembles sodium sulphate both in taste and in effect, operating as a purgative in the dose of from one to two drachms (3·9–7·5 Gm.). From the circumstance that manganese had been found in small proportion in the blood, it was conjectured that this metal, like iron, might play an important part in the human economy, and trial was made of it in *anæmia*, with the hope that it might prove a useful adjuvant of the chalybeates as a reconstructive agent. When given with iron, its use was certainly in many instances followed by the most satisfactory results; but it may be questioned whether the beneficial effects were in any respect greater than those which the iron would have produced without such an auxiliary; and where manganese has been used alone in anæmic cases it has generally failed. Dr. Garrod, of London, after a fair trial of it, pronounced against it. (*Med. Times and Gaz.*, Feb. 1863.) The dose of manganese sulphate as a tonic is from five to twenty grains (0·33–1·3 Gm.). It may be given dissolved in a flavored syrup.

MANNA. U. S. Manna.

(MĂN'NĄ.)

"The concrete, saccharine exudation of Fraxinus Ornus, Linné (nat ord. Oleaceæ)." *U. S.*

Manne, *Fr.;* **Manna,** *G., It.;* **Maná,** *Sp.*

Manna is said to be obtained from several other trees besides *Fraxinus ornus*, among which *F. rotundifolia*, *F. excelsior*, and *F. parviflora* have been particularly designated. Many saccharine substances, generally exudations from plants, have, from their resemblance to this substance, obtained the name of manna, and attracted more or less attention from writers. They are described in a note.*

* *False Mannas.* An efflorescence of mannite is said to occur upon certain sea-weeds upon exposure to the air. (*Journ. de Pharm.*, Avril, 1859.) The term "manna" has been applied to certain substances which have no relation with true manna, notably to the lichen *Lecanora esculenta*, which at times has suddenly fallen like rain over immense tracts of country, from Persia to the African Sahara. It occurs in the form of small roundish lumps, from the size of a pin's head to that of a pea, yellowish or grayish externally and whitish within, hard, inodorous, and insipid. It has been affirmed that this lichen does not contain starch, but it is really used as an article of food, and good bread is said to have been made out of it. (*Nature*, Jan. 1891.) It is probable that it is the manna of Scripture.

The proper false mannas, exudations from various trees, are best considered under the headings of the countries which yield them:

European False Manna, or *Briançon manna*, an exudation from the common European larch (*Larix europæa*, or *Pinus larix*), differs chemically from ordinary manna in containing no mannite. Berthelot found in it a peculiar sugar, analogous to that of the cane, which he named *melezitose*. (See *A. J. P.*, 1859, p. 61.) To this the formula $C_{18}H_{32}O_{16} + 2H_2O$ is given.

American False Manna. A substance resembling manna, of a sweet, slightly bitter and terebinthinate taste, and actively purgative, exudes from incisions in *Pinus lambertiana*, of Oregon, and is used by the natives. (*Nat. of U. S. Expl. Exped.*, v. 232.) M. Berthelot has extracted from this product a peculiar saccharine principle, which he calls *pinite*. It is very sweet, but does not undergo the vinous fermentation. (See *A. J. P.*, xxviii. 157.) Pinite

Fraxinus ornus. L. *Sp. Pl.* (1753) 1057; Willd. *Sp. Plant.* iv. 1104; *B. & T.* 170.—*Ornus europæa.* Persoon, *Synops.* i. 9; Lindley, *Flor. Med.* 547; Carson, *Illust. of Med. Bot.* ii. 8, pl. 61. The *flowering ash* * is a tree of moderate height, usually from twenty to twenty-five feet, very branching, with opposite, petiolate, pinnate leaves, composed of three or four pairs of leaflets, and an odd one at the end. The leaflets are oval, acuminate, obtusely serrate, about an inch and a half in length, smooth, of a bright green color, and supported on short footstalks. The flowers are white, and usually expand with the leaves. They grow in close panicles at the extremities of the young branches, and have a very short calyx with four teeth, and four linear lanceolate petals.

Both *Fraxinus ornus* and *Fraxinus rotundifolia* are natives of Sicily, Calabria, and Apulia; and both contribute to supply the manna of commerce. The former is cultivated in Sicily, yields manna after the eighth year, and continues to yield it for ten or twelve years, when it is usually cut down and young sprouts are allowed to grow up from the root. (Stettner, *Archiv d. Pharm.*, liii. 194.) During the hot months the juice exudes spontaneously from the bark, and concretes upon its surface; but, as the exudation is slow, it is customary to facilitate the

was for a long time classed among the sugars, but the latest researches seem to show that it is a pentahydric phenol derived from hexahydrobenzene. The formula is $C_6H_{12}O_5$.

California Manna, or *Father Picolo's Manna.* Proust (*Ann. d. Chim.*, 1806, 145) alludes to a manna mentioned by Father Picolo as being deposited on a species of grass in California. J. U. Lloyd (*A. J. P.*, 1897, 337) believes Picolo's manna to be a saccharine deposit, caused by aphides on *Phragmites communis.* It is apparently still collected by the Indians.

African False Mannas. Turkish Manna is a product from a species of larch (*Echinops persica*), and is obtained by treating the cocoons of a coleopterous insect (*Larinus maculatus*) with hot water, filtering, and crystallizing the sugar. From it M. Berthelot obtained a new variety of sugar, *trehalose*, $C_{12}H_{22}O_{11} + 2H_2O$. (*Gaz. Méd. de Paris*, 1857.) *Larix cedrus*, of Mount Lebanon, yields a similar product, which has some repute in Syria as a remedy in phthisis. (*P. J. Tr.*, xiii. 411.) In the neighborhood of Diarbekir, in Asiatic Turkey, a saccharine substance, known as *Diarbekir manna*, is found on the leaves of dwarf oaks, from which it appears to be exuded. (*Ibid.*, Nov. 1862, p. 546.) The manna of the oak of Kurdistan, spoken of by Flückiger, is probably the same as that of Diarbekir, which may be its entrepôt. According to Flückiger, this consists chiefly (90 per cent.) of a crystallizable sugar. It deviates to the right the plane of polarized light, and reduces in the cold the solution of copper oxide in soda and glycerin. This manna contains a mucilage, but no cane sugar or dextrin. (*Journ. de Pharm.*, Avril, 1873, p. 335.) *Quercus vallonea*, Kotschy, and *Q. persica*, Jaub. et Spach, yield "oak manna," through insect agency, while certain species of *Echinops* (probably *E. persica*, Fisch.) yield the singular manna-like substance that is known as *Trehala* in Syria and as *Shukkar Tigal* in India. *Pyrus glabra* yields a manna which is collected by the people of Luristan, in Persia. It has long been known that *Salix fragilis* and probably other species of willow yield to the Persians a manna-like exudation. According to M. Raby (*L'Union Pharm.*, Mai, 1889), there are two varieties, *chirkhest* and *bidenguêbin*, which contain respectively, according to the analysis of Ludwig, *chirkhestite* ($C_6H_{14}O_6$), allied to sorbite, and *bidenguebinose* ($C_{12}H_{22}O_{11}$), allied to melezitose. Whether these mannas are really distinct from those sold in the Indian bazaars as coming from Afghanistan and Persia seems uncertain. Of these bazaar mannas the most important is the *Shir-koit* or *Oriental* manna. By Haussknecht it is referred to *Atraphaxis spinosa*; but Mr. J. E. T. Aitchison states that it is yielded by the *Cotoneaster nummularia*, Fisch. et Mey., a tall, stout shrub, whose smaller branches in July become covered with an exudation, which is eaten as a sweetmeat, and exported in quantity to Russia and India. The second variety, *Taranjabin*, is yielded by the camel-thorn, *Alhagi camelorum*, Fisch., in Persia and Afghanistan, and probably by *Alhagi maurorum* of De Candolle, a leguminous thorny shrub abundant in India,—if indeed the two species be distinct. According to A. Villiers, it is nearly pure melezitose. (*P. J. Tr.*, 3d ser., vii. 917.) A third kind of manna is *Gazanjabin*, or *Gazanjabin*, yielded by *Tamarix gallica*, Linn., var. *mannifera*; a fourth kind is obtained from the *Salsola fœtida*, Dec. (*P. J. Tr.*, Dec. 11, 1886, 467.) The *tamarisk* of Northern Africa (*Tamarix gallica*, Ehr.), which produces the small *tamarisk galls* of Mogador, containing 40 per cent. of tannic acid (*A. J. P.*, 1878, p. 27; also *N. R.*, 1877, p. 41), according to Burckhardt also gives origin to a species of manna that is used by the Bedouin Arabs near Mount Sinai with their food. This substance, however, according to Mitscherlich, contains no mannite, but consists wholly of mucilaginous sugar. M. Berthelot found a manna from Sinai to consist of 55 per cent. of cane sugar, 25 of levulose and glucose, and 20 of dextrin and analogous substances. (*Annales de Chim. et Phys.*, lxvii.)

Persian Manna, or *Gez*, has been identified (*Chem. and Drug.*, 1894, 790) as being derived from *Astragalus anisacanthus*, and is found in the districts of Khonsar, Feridan and Chahar Mahal, and Ispahan. In the form of sweetmeat, having the appearance of flour, it is sent all over Persia and much esteemed.

Australian Mannas. A manna-like exudation on the *Eucalyptus mannifera*, growing in New South Wales, contains a saccharine matter called *melitose*, different in properties from mannite and from all the varieties of sugar, though isomeric with glucose. It is susceptible of the vinous fermentation. (See *A. J. P.*, xxviii. 157.) *Lerp* is produced upon the leaves of *Eucalyptus dumosa*, when very small, and sometimes appears spread over large extents of country like a kind of snow. The natives use it for food. It is a complex body, containing an unfermentable sugar, *eucalin*, gum, starch, inulin, and lignin. (*Journ. de Chim. et de Pharm.*, xvi. 240.) It is said to be a secretion from an insect, formed into minute cells, each of which is the abode of one of the insects. (See *A. J. P.*, 1862, p. 547.) *Myoporum platycarpum*, R. Br., the *sandalwood-* or *dogwood-tree* of Australia, exudes an exceedingly sweet and pleasant manna, which is much used as an article of food. Mr. F. W. Passmore obtained from *Eucalyptus gumii* a sugar termed *melitriose.* (*P. J. Tr.*, 1891, 718.)

New South Wales Manna. According to R. T. Baker (*Journ. and Proc. Roy. Soc. New South Wales*, xxx., 1897), this manna is produced in the form of nodules at the nodes of the stems of the blue grass *Andropogon annulatus.* It contains numerous crystals of mannite, amounting, according to the analysis of Dr. H. G. Smith, to 50 per cent.

* A syrup prepared from the inner bark of this tree has been employed in Europe by Dr. Devergie, with supposed advantage, in chronic *eczema* and *impetigo.* The bark contains much tannin, and a mucilaginous principle which renders diluted alcohol a better menstruum than boiling water. (*Journ. de Pharm.*, 3e sér., ix. 347.)

process by making deep longitudinal incisions on one side of the trunk. In the following season these are repeated on the other side, and thus alternately for the whole period during which the tree yields manna, extending sometimes, it is said, to thirty or even forty years. Straw or chips are frequently placed so as to receive the juice, which concretes upon them. The manna varies in its character according to the mode of collection, the nature of the season, and the period of the year at which the exudation takes place. That procured in Sicily is said to be the best. Mr. Daniel Hanbury travelled through the old manna region, and satisfied himself that the collection of manna for commercial purposes is confined almost exclusively to Sicily. (*P. J. Tr.*, Nov. 1872, 421.) But a more recent writer (*Ibid.*, Nov. 1879) asserts that the manna-trees are still cultivated in Calabria. For still later information on manna collection in Sicily, see notes by J. S. Ward. (*Ibid.*, 1893, 381.)

In commerce three varieties are distinguishable:

1. Flake Manna, or *manna canulata*, is the purest variety. It exudes spontaneously, or from incisions, during the hottest and dryest weather in July and August. According to Stettner, it is furnished by the upper incisions upon the trunk, while the lower incisions yield the inferior varieties. It is in irregular, unequal pieces, often several inches long, resembling stalactites, rough, light, porous, brittle, whitish or yellowish-white, and frequently concave on the surface by which they were attached to the trunk, and which is often soiled by impurities, sometimes by adherent fragments of the bark. When broken, these pieces exhibit a crystalline or granular structure. This variety is sometimes in small fragments, generally less than an inch in length.

2. Common Manna—the *manne en sorte* of French pharmacy—is next in quality, and is collected in September and the beginning of October, when the heat of the weather has begun to moderate. The juice does not now concrete so readily, and a portion, falling on the ground at the root of the tree, becomes more or less mixed with impurities, and forms imperfectly solid masses, which require to be further dried in the sun. Common manna consists of whitish or yellowish fragments, similar to the pieces of flake manna, but much smaller, mixed with a soft, viscid, uncrystallized brownish matter, identical with fat manna.

3. Fat Manna is collected in the latter part of October and November, when the weather is cooler and rains are more common. The juice is now still less disposed to concrete, and flowing down the trunk is received in a small excavation at its base. As found in commerce, it is in the form of a soft, viscous mass, containing few crystalline fragments, of a brown or yellowish-brown color, and full of impurities. The U. S. Pharmacopœia directs that such manna should be rejected.*

Properties. Manna is officially described as "in flattish, somewhat three-edged pieces, occasionally 20 Cm. long, and 5 Cm. broad, usually smaller; friable; externally yellowish-white, internally white, porous, and crystalline; or in fragments of different sizes, brownish-white and somewhat glutinous on the surface, internally white and crystalline; odor honey-like; taste sweet, slightly bitter and faintly acrid. On heating 5 parts of Manna with 100 parts of alcohol to boiling, and filtering, the filtrate should rapidly deposit separate crystals of mannite. Manna consisting of brownish, viscid masses containing few or no fragments of a crystalline structure should be rejected." *U. S.* Manna has a slight, peculiar odor, and a sweet taste, which in the impure kinds is also very nauseous, but in the finest flake manna scarcely so much so as to be disagreeable. Its sp. gr. is 0·834. It melts with heat, and takes fire, burning with a blue flame. When pure it is soluble in three parts of cold and in its own weight of boiling water. From a boiling saturated aqueous solution it separates in partially crystalline masses on cooling.

* *Fictitious Manna.* Attempts have been made to counterfeit manna; but the facility of detection renders such frauds unprofitable, and they are not often practised. Dr. R. P. Thomas described (*A. J. P.*, xxiv.) a sophisticated manna which differed from the genuine drug both in sensible and in chemical properties, not even containing mannite. Baumé describes a method in which common manna is purified so as to resemble flake manna. It consists in dissolving common manna in a little water, allowing the liquid to settle, decanting it in order to separate the impurities, then inspissating it so that it will congeal on cooling, and immersing threads in the inspissated liquid, several times successively, in the manner practised by candle-makers. It may be still further purified by the use of animal charcoal. Thus prepared, it contains less mannite than flake manna, and less of the nauseous principle, but is said not to operate less effectively as a laxative. A fictitious manna is described by Mr. Edmond Histed (*P. J. Tr.*, April, 1870) as having been taken from Paris to London, which bears a close resemblance to flake manna, for which it might be mistaken upon a hasty notice. The resemblance is, moreover, increased by the fact that it contains mannite, of which Mr. Histed obtained 40 per cent., while fine natural flake manna yielded him 70 per cent. Closely examined, it is found to differ essentially from genuine flake manna, showing no crystals of mannite when broken, not having the taste and smell characteristic of good manna, and, besides, being cleaner, lighter-colored, more solid, and making a clearer solution in water. (See *A. J. P.*, 1870.) May not this have been a specimen of artificial flake manna, prepared from the inferior or common manna?

Alcohol also dissolves it. Boiling alcohol will dissolve 15 parts of it, and upon cooling deposit beautiful crystals of mannite. Fourcroy and Vauquelin found manna to consist of—1, a peculiar sweet principle, *mannite*, which constitutes 75 per cent.; 2, a variety of sugar; 3, a yellow nauseous matter, upon which the purgative property is thought chiefly to depend; and, 4, a little mucilage. Leuchtweiss obtained from 105 parts of manna 11·6 of water, 0·4 of insoluble matter, 9·1 of sugar, 42·6 of mannite, 40·0 of a mixture of mucilaginous matter containing mannite, resin, organic acid, and a nitrogenous substance, and 1·3 of ashes. In *manna canellata in fragmentis* he found 37·6 per cent. of mannite, and in *manna Calabrina* 32 per cent. (*Pflanzenstoffe*, 2d ed., p. 180.) M. Buignet discovered in manna a considerable proportion of dextrin. He appears to have been led to this discovery by observing a very energetic dextrogyrate power in flake manna, which could not be owing to the saccharine matter it contained, because the same power continued after all the sugar had been destroyed by fermentation. Dextrin forms about one-fifth part of flake manna, and a much larger part of the inferior kinds. It may be readily obtained separate by triturating 200 parts of flake manna with 400 of alcohol of 70° F. in successive portions, filtering the resulting mixture, by which the mannite is left behind, and then separating the sugar and dextrin contained in the clear liquor. This is done by concentrating the liquor to a syrupy consistence, and adding about 10 parts of alcohol at 90° F. The mixture separates into two layers, the upper consisting of a strong alcoholic solution of sugar, the lower of a saturated solution of dextrin in weak alcohol. The latter is separated, washed repeatedly with alcohol at 90° F., and then, after dilution with water, decolorization, and filtration, is evaporated gently by a water-bath till it ceases to lose weight. The substance remaining is dextrin. The saccharine matter of manna is a mixture of cane sugar and levulose, which are in such proportion as almost to neutralize their reciprocal optic properties. All the forms of commercial manna contain both sugar and dextrin, and, though the quantity of the two jointly varies considerably, yet their relative proportion is invariable, being 2 mols. of dextrin and 1 mol. of sugar. This is the same result that is reached in the saccharification of starch; and the inference is fair that the dextrin and sugar in manna are the result of a transformation of starch in the plant. (*Journ. de Pharm. et de Chim.*, Juillet, 1868.) It is owing to the presence of glucose and dextrin that manna is capable of fermenting. Flückiger found in all samples of mannite examined a small amount of a dextrogyrate mucilage, which is precipitated by neutral lead acetate, and yields mucic acid when boiled with strong nitric acid. The greenish color of certain pieces of manna is produced by *fraxin*, $C_{16}H_{18}O_{10}$, a glucoside closely resembling *æsculin*. Fraxin crystallizes in colorless prisms, easily soluble in hot water and in alcohol, and has a faintly astringent and bitter taste. By dilute acids it is resolved into *fraxetin*, $C_{10}H_8O_5$, and *glucose*, $C_6H_{12}O_6$. Even its dilute solutions are fluorescent. (*Pharmacographia*, 2d ed.)

Mannite (*mannitol*) is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and deposited when it cools. Its composition is $C_6H_{14}O_6$, and it is considered as belonging to the class of *hexatomic alcohols*. If mixed with chalk and cream-cheese and kept for some weeks at the temperature of 40° C. (104° F.), it yields alcohol largely, with the disengagement of carbonic acid and hydrogen and the production of lactic acid. No fungus is produced, as in the ordinary fermentation of sugar. (Berthelot, *Journ. de Pharm.*, xxx.) With lime, barium and strontium oxides, it forms definite compounds, soluble in water, and precipitable from their aqueous solutions by alcohol. (*Ibid.*, Jan. 1860.) It does not reduce an alkaline solution of copper oxide; and a test of its purity is thus presented. (*A. J. P.*, Jan. 1861, p. 26.) Its optical activity can be observed only after the addition of borax. It is then found to be dextro-rotatory. Emil Fischer has shown that there are three mannites obtainable: the ordinary mannite is the dextro-rotatory variety, and is always obtained in the reduction of *a*-mannose with sodium amalgam; a lævo-rotatory variety is obtained by the reduction of *l*-mannose; and an inactive mannite is obtained from the inactive mannose. These three physical isomers differ slightly in their fusing points and crystalline form. The native variety may be obtained by boiling manna in alcohol, allowing the solution to cool, and redissolving the crystalline precipitate: pure mannite is now deposited. Another method is to dissolve flake manna in water, precipitate by solution of lead subacetate, filter, throw down the excess of lead by sulphuric acid, evaporate the solution, and mix with alcohol. On cooling, the mannite is deposited. (Bonsall, *Arch. der Pharm.*, cxxxiv. 70.) This principle has been found in numerous vegetables. It is said to be gently laxative in the dose of from one to two ounces (31·1–62·2 Gm.).

Manna, when long kept, acquires a deeper color, softens, and ultimately deliquesces into a liquid, which, on the addition of yeast, undergoes the vinous fermentation. This is probably owing to its conversion into sugar by the absorption of enough oxygen to cause it to pass over into some variety of glucose or fermentable sugar. That which is dryest resists this change the longest. It is said that manna recently gathered is less purgative than it afterwards becomes.

Medical Properties and Uses. Manna is a gentle laxative, usually operating mildly, but in some cases producing flatulence and pain. It is usually prescribed with other purgatives, particularly senna, rhubarb, magnesia, and the neutral salts, the taste of which it conceals, while it adds to the purgative effect. The dose for an adult is from one to two ounces (31·1–62·2 Gm.); for children, from one to four drachms (3·9–15·5 Gm.). It is usually given dissolved in water or some aromatic infusion; but the best flake manna may be administered in substance. Manna forms a combination with iron, which it preserves against change. (See *P. J. Tr.*, March, 1873.)

MARRUBIUM. U. S. Marrubium. [Horehound.]

(MĄR-RŪ′BI-ŬM.)

"The leaves and tops of Marrubium vulgare, Linné (nat. ord. Labiatæ)." *U. S.*

Herba Marrubii; Herbe de Marrube blanc, Marrube blanc, *Fr.;* Andornkraut, Weisser Andorn, *G.;* Marrubio, *It., Sp.*

Marrubium vulgare. L. *Sp. Pl.* (1753) 583; Willd. *Sp. Plant.* iii. 111; *B. & T.* 210. *White Horehound* has a perennial fibrous root, and numerous annual stems, which are quadrangular, erect, very downy, and from twelve to eighteen inches high. The leaves are about an inch long, roundish-ovate, dentate or deeply serrate, obtuse, wrinkled, veined, downy above, hoary on the under surface, and supported in pairs on strong footstalks. The flowers are white, and in crowded axillary woolly whorls. The calyx is tubular, and divided at the margin into ten narrow segments, which are hooked at the end. The corolla is also tubular, whitish, with a labiate margin, of which the upper lip is bifid, the under reflected and three-cleft, with the middle segment broad and slightly scalloped: stamens four, included. The seeds are four, in the bottom of the calyx. The plant is a native of Europe, but has been naturalized in this country, where it grows on the roadsides, and flowers in July and August. The herb has a strong, rather agreeable odor, which is diminished by drying and lost by keeping. Its taste is bitter and durable. The bitterness is extracted by water and alcohol. It contains a volatile oil, resin, tannin, lignin, and a bitter principle called *marrubiin* by Mein. This marrubiin is slightly soluble in cold water, crystallizes from alcohol in prismatic and from ether in tabular crystals, is not precipitated by tannin, and has a very bitter and somewhat acrid taste. The fusing point of the crystals is 160° C., according to Kromayer. Marrubiin was afterwards obtained by Harms (*Archiv der Pharm.*, 116, 141), by Hertel (*A. J. P.*, June, 1890), and by Morrison (*Ibid.*, July, 1890). A more recent study was by Matusow (*Ibid.*, 1897, 201). He gives to it the formula $C_{30}H_{43}O_6$, and states the melting point of the purified substance to be from 154° to 155° C. According to him, it is not a glucoside.

Medical Properties and Uses. Horehound is tonic, in large doses laxative, and may be so given as to increase the secretion from the skin, and occasionally from the kidneys. It was formerly considered a valuable deobstruent, and was recommended in *chronic hepatitis*, *jaundice*, *amenorrhœa*, *phthisis*, and various *cachectic affections*. By its gently tonic powers it may have proved advantageous in some of these complaints; but it exerts no specific influence over any of them, and has passed mainly from the hands of physicians into domestic use. It is employed chiefly in *catarrh*, and in other *chronic affections of the lungs*, attended with cough and copious expectoration. The infusion, made in the proportion of an ounce of the herb to a pint of boiling water, may be given in wineglassful doses. The dose of the powder is from thirty grains to a drachm (1·95–3·9 Gm.). The medicine is also much used in syrup and candy.

MASSA COPAIBÆ. U. S. Mass of Copaiba. [Solidified Copaiba.]

(MĂS′SĄ CŌ-PĀ′I-BÆ.)

Pilulæ Copaibæ, *U. S.* 1870; Pilules de Copahu, *Fr.;* Copaiva-Pillen, *G.*

"Copaiba, *ninety-four grammes* [or 3 ounces av., 138 grains]; Magnesia, *six grammes* [or 93 grains]; Water, *a sufficient quantity*. Triturate the Magnesia with a little Water, in a capsule, until the powder is uniformly dampened throughout. Then gradually incorporate with it the

Copaiba, so that a uniform mixture may result, place the capsule on a water-bath, and heat during half an hour, frequently stirring. Lastly, transfer the mixture to a suitable vessel, and set this aside until the mass has acquired a pilular consistence." *U. S.*

This preparation is identical with that formerly official. When copaiba is mixed with pure magnesia, it gradually loses its fluidity, forming at first a soft tenacious mass, and ultimately becoming dry, hard, and brittle. The quantity of magnesia, and the length of time requisite for this change, vary with the condition of the copaiba; being greater in proportion to the fluidity of this substance, or, in other words, to its amount of volatile oil. The quantity of magnesia directed by the Pharmacopœia, one-sixteenth of the weight of the copaiba, is sufficient to solidify the latter, as it is often found in commerce, in the course of six or eight hours; but when the copaiba is fresh, or has been kept in closely-stopped bottles, and retains, therefore, nearly the whole of its oil, it is often necessary either to augment the proportion of magnesia, or to expose the mixture for a much longer time, or to diminish the volatile oil of the copaiba by evaporation. The magnesia combines chemically with the *copaivic acid* or hard resin, but in relation to the volatile oil acts merely as an absorbent; for, when the solidified mass is submitted to the action of boiling alcohol, a part is dissolved, abandoning the magnesia with which it was mixed, while the resin, combined with another portion of magnesia, remains undissolved. Varieties of copaiba, therefore, are solidifiable by magnesia directly in proportion to the hard resin they contain, and inversely in proportion to the volatile oil; the soft resin being indifferent. According to Guibourt, copaiba not solidifiable by magnesia may be made so by adding one-sixth of Bordeaux or common European turpentine.

Calcium hydrate produces the same effect as magnesia, and, as stated by M. Thierry, in a shorter time, if employed according to his formula. He takes 15 parts of copaiba and 1 part of slaked lime, mixes them in a marble mortar, transfers the mixture to an open vessel, places this upon a sand-bath, and sustains the heat for four hours, occasionally stirring. The calcium hydrate must have been freshly prepared from recently-burnt lime. The mixture loses only a twenty-fourth of its weight, chiefly the water of the hydrate. (*Journ. de Pharm.*, 3e sér., i.)

Notwithstanding the accuracy of the above statements, it sometimes happens that copaiba of undoubted genuineness, and with a due proportion of volatile oil, will not solidify with magnesia or with lime; and the cause of this uncertainty of action remained long undetermined. At length it was ascertained by M. Roussin, through a series of well-devised experiments, that the occasional want of solidifying power is owing to the absence of water, the presence of a certain quantity of which, whether in the copaiba or in the earth employed, is essential to the combination of the magnesia or lime with the copaivic acid. In instances of deficiency in the solidifying property, M. Roussin recommends that the copaiba be shaken for some time with about one-twentieth of its weight of water, and then allowed to stand for some days in a warm place so as to allow all the water in excess to subside. The copaiba may now be decanted and preserved. Thus prepared, it will solidify with one-sixteenth of calcined anhydrous magnesia in the course of a few days, and often in twenty-four hours. (*Journ. de Pharm.*, 4e sér., i.) M. Rabot proposes a process by which the copaiba can in a few minutes be solidified to a consistence fit for preparing pills. He mixes pure copaiba with one-sixteenth of its weight of magnesia, previously slightly hydrated by sprinkling on it some drops of water, equal to about one-tenth of its weight, then introduces the capsule containing the mixture into boiling water, and keeps it thus by means of a water-bath for several minutes. The immediate consolidation is explained by the fact that the magnesia combines most readily with the resin of copaiba at a temperature of about 50° C. (122° F.), a heat which in no degree impairs the virtue of the medicine. (*Ibid.*, ii.) For Kirchmann's method of making the mass from an emulsion with the aid of borax, see *Amer. Drug.*, 1884.

Pills may also be made by incorporating vegetable powders with copaiba so as to bring it to the proper consistence; but this method has the inconvenience of greatly increasing the bulk. Spermaceti and wax have been proposed as excipients; and the latter, which was originally suggested by J. F. Simon, is recommended on account of its retaining all the volatile oil, and, with some vegetable powder, forming a mass that will retain its plasticity for years. One part, each, of wax, copaiba, and vegetable powder will answer the purpose, when the copaiba does not contain more than 50 per cent. of volatile oil; but if richer than this it will require more of the excipient. To prepare the pills, melt the wax at the lowest possible heat, then gradually add the copaiba, and lastly incorporate some vegetable powder, as pulverized liquorice root, for example, with the other ingredients. (See *A. J. P.*, Jan. 1863.) In the preparation of the pills of copaiba, care should be taken to divide the mass before it has become too hard.

The advantage of this preparation is that the copaiba is brought to the state of pill with little increase of bulk. Five grains (0·33 Gm.) of the mass make a pill of convenient size; of these from two to six may be taken for a dose twice or three times a day.

MASSA FERRI CARBONATIS. U. S., Br. Mass of Ferrous Carbonate.

[Vallet's Mass.]

(MĂS'SĄ FĔR'RĪ CĂR-BŌ-NĀ'TĪS.)

Pilula Ferri Carbonatis, *Br.* 1885, also *U. S.* 1870; Pill of Carbonate of Iron, Vallet's Ferruginous Pills; Pilulæ Ferri Carbonici, *P. G.;* Pilulæ Ferratæ Valleti; Vallet's Mass; Pilules de Carbonate ferreux, Pilules ferrugineuses, *Fr.;* Vallet'sche Pillen, *G.*

"Ferrous Sulphate, in clear crystals, *one hundred grammes* [or 3 ounces av., 230 grains]; Sodium Carbonate, *one hundred grammes* [or 3 ounces av., 230 grains]; Clarified Honey, *thirty-eight grammes* [or 1 ounce av., 149 grains]; Sugar, in coarse powder, *twenty-five grammes* [or 385 grains]; Syrup, Distilled Water, each, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 230 grains]. Dissolve the Ferrous Sulphate and the Sodium Carbonate, each separately, in *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of boiling Distilled Water, and, having added *twenty cubic centimeters* [or 324 minims] of Syrup to the solution of the Iron salt, filter both solutions, and allow them to become cold. Introduce the solution of Sodium Carbonate into a bottle having a capacity of about *five hundred cubic centimeters* [or 16 fluidounces, 435 minims], and gradually add the solution of the Iron salt, rotating the flask constantly or frequently, until carbonic acid gas no longer escapes. Add a sufficient quantity of Distilled Water to fill the bottle; then cork the bottle and set it aside, so that the ferrous carbonate may subside. Pour off the supernatant liquid, and, having mixed Syrup and Distilled Water in the proportion of *one volume* of Syrup to *nineteen volumes* of Distilled Water, wash the precipitate with the mixture by decantation until the washings no longer have a saline taste. Drain the precipitate on a muslin strainer, and express as much of the Water as possible. Lastly, mix the precipitate at once with the Honey and Sugar, and, by means of a water-bath, evaporate the mixture in a tared capsule, with constant stirring, until it is reduced to *one hundred grammes* [or 3 ounces av., 230 grains]." *U. S.**

The effect of saccharine matter in protecting iron from oxidation has been explained under the heads of *Ferri Carbonas Saccharatus* and *Syrupus Ferri Iodidi*. The U. S. mass of ferrous carbonate is another example of a ferruginous preparation in which the iron is protected from further oxidation by the same means. The salts employed are the same as those used for obtaining the formerly official ferric subcarbonate; but in forming that preparation the carbonate which is at first precipitated absorbs oxygen, and loses nearly all its carbonic acid in the processes of washing and drying. When, however, as in the U. S. formula above given, the reacting salts are dissolved in weak syrup instead of water, and the washing is performed with weak syrup also, the absorption of oxygen and loss of carbonic acid during the separation of the precipitate are almost completely prevented. It only remains, therefore, to preserve it unaltered, and to bring it to the pilular consistence, and this is effected by admixture with honey and sugar, and evaporation by means of a water-bath. It is essential to the success of this process that the ferrous sulphate should be pure; otherwise some ferric oxide will be present in the product. The process is that of M. Vallet, of Paris, after whom the preparation is popularly called. The present U. S. process differs from that of 1870 in omitting to direct boiled water for washing the precipitated ferrous carbonate. This is an important omission, because there is apt to be some oxidation of the salt, due to the air in the water. The British Pharmacopœia 1898 omitted Vallet's mass. (See *Ferri Carbonas Saccharatus.*) Gonnermann prepares *powdered Vallet's mass* by mixing intimately ten parts of milk sugar and five parts of powdered liquorice root with sufficient freshly precipitated ferrous carbonate to make, when dried, thirty-five parts, and adding enough powdered liquorice root to make the whole weigh forty parts. (*Pharm. Post*, 1893, 238.)

* Wm. Silver Thompson states that the mass is more stable when made by the following formula than when prepared in the official manner. Take of Ferrous Sulphate eight ounces; Sodium Bicarbonate six ounces; Sugar, in fine powder, four and a half ounces; Clarified Honey half an ounce; Syrup, Water, each, a sufficient quantity. Dissolve each salt separately in water, add the sodium solution to the iron solution gradually, constantly stirring until the effervescence ceases, then add about a fluidounce of syrup, and again stir. After the carbonate has subsided, draw off the supernatant liquid, and repeat the washing with cold water slightly sweetened with syrup, until the washings are free from a saline taste; when, having again drawn off the supernatant liquid, transfer the precipitate to a muslin cloth, and express as much of the water as possible. To the precipitate, in a porcelain dish placed over a water-bath, add the honey and sugar, and with frequent stirring evaporate to the pilular consistence. (*A. J. P.*, 1870, p. 30.)

Properties. The U. S. preparation is in the form of a soft pilular mass, of a dark greenish-gray color, becoming black on exposure, and with a strong ferruginous taste. When carefully prepared, it is wholly and readily soluble in acids. It contains nearly half its weight of ferrous carbonate. The corresponding pill, obtained from the saccharine carbonate, may be supposed to contain one-third of ferruginous matter.

Medical Properties. The U. S. mass of ferrous carbonate, or Vallet's ferruginous mass, is admirably adapted to cases in which pure chalybeate preparations are indicated. It is, therefore, extremely valuable in simple *anæmia* and *chlorosis*. Its chief merits are its unchangeableness, its freedom from astringency, and its ready solubility in acids. Dose, from three to five grains (0·20–0·33 Gm.), in pill-form, after meals.

MASSA HYDRARGYRI. U. S. (Br.) Mass of Mercury. [Pilula Hydrargyri. Blue Mass. Blue Pill.]

(MĂS'SĄ HĬ-DRÄR'ĢĮ-RĪ.)

Pilula Hydrargyri, *Br.*, Mercury Pill; Pilulæ Hydrargyri, *U. S.* 1870; Pills of Mercury, Mercurial Pill; Pilulæ Cœruleæ, Massa Cœrulea; Blue Pills; Pilule de Mercure, Pilules bleues, *Fr.*; Mercurial Pillen, *G.*

"Mercury, *thirty-three grammes* [or 1 ounce av., 72 grains]; Glycyrrhiza, in No. 60 powder, *five grammes* [or 77 grains]; Althæa, in No. 60 powder, *twenty-five grammes* [or 385 grains]; Glycerin, *three grammes* [or 46 grains]; Honey of Rose, *thirty-four grammes* [or 1 ounce av., 88 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Mercury with the Honey of Rose and Glycerin until it is extinguished. Then gradually add the Glycyrrhiza and Althæa, and continue the trituration until globules of mercury are no longer visible under a lens magnifying at least ten diameters." *U. S.*

"Mercury, 2 *ounces* (Imperial) or 40 grammes; Confection of Roses, 3 *ounces* (Imp.) or 60 grammes; Liquorice Root, in fine powder, 1 *ounce* (Imp.) or 20 grammes. Rub the Mercury with the Confection of Roses until metallic globules are no longer visible; add the Liquorice Root; beat together until thoroughly mixed." *Br.*

The mercury constitutes one-third of the mass. The ingredients for this mass do not differ essentially from those of the U. S. 1880 formula. The U. S. 1890 process is well suited for the needs of the pharmacist, as the mass can be made with ordinary apparatus extemporaneously.

The precise condition of the mercury in this preparation is somewhat uncertain. By far the greater proportion is in a state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into mercurous oxide, and that this is the ingredient upon which the activity of the pill depends. The supposed oxidation is attributed partly to the influence of the air upon the surface of the metal, greatly extended by the separation of its particles, partly to the action of the substance used in the trituration. If the mercury is not oxidized during the trituration, there can be little doubt that it becomes so, to a slight extent, by subsequent exposure. The obvious changes which the mass undergoes by time can be explained in no other way; and mercurous oxide is asserted to have been actually extracted from old mercurial pill. Mr. Harold Senier analyzed a number of samples of blue mass, with the view of determining the amount of metallic mercury and of mercurous and mercuric oxides. The results showed that the latter gradually increased in quantity with the age of the blue mass, which, 18 hours after preparation, contained but a trace of mercurous oxide; after three months, 0·24 per cent. of mercuric and 0·62 per cent. of mercurous oxides were obtained, and in another sample, 0·44 and 1·60 per cent. respectively. After two years, 1·80 per cent. of mercuric and 4·22 per cent. of mercurous oxides were present. (*P. J. Tr.*, 1876.) Nevertheless, it scarcely admits of dispute that the metal, independently of oxidation out of the body, is capable of producing the peculiar mercurial effects when introduced into the stomach, probably undergoing chemical changes there. The U. S. P. 1890 provides a test which limits the quantity of mercurous oxide and proves the absence of mercuric oxide; it will be difficult for the ordinary "blue mass" of commerce to withstand these requirements: "If a portion of the Mass be triturated, in a mortar, with warm acetic acid, the filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of *mercurous oxide*). If another portion of the Mass be digested with warm diluted hydrochloric acid and a little purified animal charcoal, the filtrate should not be affected by hydrogen sulphide test-solution, or by stannous chloride test-solution (absence of *mercuric oxide*)." *U. S.* According to M. Mialhe, mercury is slowly converted into corrosive sublimate in the stomach, under the combined agency of air and sodium chloride. All agree that the efficacy of the preparation is proportionate to

the extinction of the mercury; in other words, to the degree in which the metallic globules disappear. This extinction may be effected by trituration with various substances; and manna, syrup, honey, liquorice, mucilage, soap, guaiac, and extract of dandelion have been recommended, among others, for this purpose; but the confection of roses has been adopted in all the Pharmacopœias, as less liable to objection than any other. The mercury is known to be completely extinguished when, upon rubbing a small portion of the mass with the end of the finger upon a piece of paper or glass, no globules appear; or more accurately by the microscopic test of the U. S. Pharmacopœia. Powdered liquorice root and powdered marshmallow root are added in order to give due consistence to the mass. The process now official was proposed by Prof. C. Lewis Diehl, and is very satisfactory. It is possible for the apothecary to make moderate quantities extemporaneously with no other appliances than the mortar and pestle. As the trituration requires to be long continued, which renders the process very laborious when conducted on the large scale, it is customary to prepare the mass by machinery. At Apothecaries' Hall, in London, the trituration is effected by the agency of steam. The machine there employed consists of "a circular iron trough for the reception of the materials, in which revolve four wooden cylinders, having also a motion on their axes." A machine for preparing blue mass, capable of being worked by hand or steam-power, was invented by Mr. J. W. W. Gordon, of Baltimore, and, having been found to answer well, was at one time in extensive use. (*A. J. P.*, xxi. 6.) We have already referred, under *Hydrargyrum cum Cretâ*, to another ingenious apparatus, invented by Dr. Squibb, by which the extinguishment of mercury is very satisfactorily effected. Formerly much of the blue mass used in this country was imported; but at present the market is chiefly supplied by our own manufacturers. The preparation slowly changes color upon being kept, assuming an olive and sometimes even a reddish tint, in consequence, probably, of the further oxidation of the mercury.*

In consideration of the incomplete extinguishment of the mercury in many specimens of the blue pill, arising from the tedious process employed, Mr. F. B. Benger proposes to obtain the metal in a state of minute division. For this purpose he adds to a solution of an ounce of stannous chloride, in a mixture of two drachms of hydrochloric acid and two ounces of cold water, a boiling hot solution of 136 grains of corrosive sublimate in four ounces of distilled water, and stirs the mixture for a few seconds. The mercury of the corrosive chloride is thrown down in the form of a black powder, to which, after the liquid has been drawn off by means of a pipette, 30 grains of sugar, 100 grains of powdered liquorice, and about a drachm of glycerin are added. The mass, being transferred to a porcelain slab, is allowed to become sufficiently dry, and then mixed with enough glycerin and liquorice to make it weigh 300 grains. (*P. J. Tr.*, ii. 165.) Theoretically, this appears to be a good process; but only a long experience of its practical advantages would justify its substitution for a plan which has been followed for so many years with results, upon the whole, so satisfactory. An obvious objection to the process is the possibility, with carelessness of manipulation, of having in the preparation a minute proportion of corrosive sublimate or stannous chloride.

The blue pill is sometimes wanted in the state of powder; but, from its peculiar constitution, it is not eligible for reduction to this form, as the mercury is disposed to aggregate during pulverization, and, from the honey it contains, it is apt, when pulverized, to attract moisture from the air. Mr. Chas. Bullock recommends the following method of preparing a powder which, as nearly as possible, represents the blue pill, in reference to its therapeutic effects:

Powdered Blue Mass. Take of finely powdered Elm-bark, finely powdered Sugar, and Mercury, equal parts, and of Alcohol a sufficiency. Rub the mercury with the powdered bark, adding from time to time enough alcohol to maintain a pasty consistence, till the mercury is completely extinguished; then spread the mass on paper to dry. When dry, powder it, add the sugar, and rub the mixture thoroughly until the powder will pass through a sieve of fine bolting-cloth. (*A. J. P.*, 1859, p. 271.)

* The mercurial mass is very apt to contain less than the due proportion of the metal. This was frequently the case with the mass as formerly imported. The fraud may be detected by the following plan of estimating the proportion of mercury, suggested by Prof. Reid, of New York, and modified by a committee of the Philadelphia College of Pharmacy. A certain weight of the mercurial mass, say fifty grains, is mixed with about one-fourth of its weight of iron filings, and introduced into a small green glass bulb, at the end of a somewhat curved tube, the open extremity of which is inserted, through a cork, into alcohol, contained in a broad-mouthed glass vial; another tube, open at both ends, passing through the cork, in order to permit the escape of uncondensed gases. Heat is then applied to the bulb by means of a spirit-lamp, is gradually increased until the glass becomes red hot, and continued for an hour. The alcohol in the vial dissolves the empyreumatic products, and, by being allowed to rise in the tube, and then expelled, serves to wash out any mercury that may be condensed upon its sides. The alcohol is poured off from the condensed mercury, which is then washed with fresh alcohol, dried, and weighed. (See *A. J. P.*, xvii.)

Medical Properties and Uses. This mass is among the mildest of the mercurials, being less liable than most others to act upon the bowels, and exercising the peculiar influence of the remedy upon the system with less irritation. It is much employed for producing the sialagogue and alterative action of mercury. For the former purpose, three grains (0·20 Gm.) may be given two or three times a day; and in urgent cases the dose may be increased. Even this preparation sometimes disturbs the bowels. It should then be given combined with a little opium, or in very minute doses, as half a grain or a grain (0·03–0·065 Gm.) of the mass, repeated every hour or two through the day, so as to allow of its absorption before a sufficient quantity has been administered to act as an irritant. With a view to the alterative effect upon the digestive organs, three grains (0·20 Gm.) may be given every night, or every other night, at bedtime, and followed in the morning, if the bowels should not be opened, by a small dose of laxative medicine. From five to fifteen grains (0·33–0·97 Gm.) of the mass are occasionally given as a cathartic, in cases requiring a peculiar impression upon the liver; but when used for this purpose it should always either be combined with or speedily followed by a more certain purgative. The *blue mass* may often be administered with advantage suspended in water by the intervention of thick mucilage; and it forms an excellent addition to the chalk mixture in *diarrhœa*, particularly that of children, when the biliary secretion is deficient or otherwise deranged.

MASTICHE. U. S. Mastic.

(MĂS'TĮ-ĊHĒ—măs'tį-kē.)

"A concrete resinous exudation from Pistacia Lentiscus, Linné (nat. ord. Anacardieæ)." *U. S.*

Mastich; Mastix, *P. G.;* Resina Mastiche; Mastic, *Fr.;* Mastice, *It.;* Almastiga, *Sp.;* Sakes, *Turk.;* Arah, *Arab.*

Pistacia lentiscus. L. *Sp. Pl.* (1753) 1026; Willd. *Sp. Plant.* iv. 753; *B. & T.* 68. The *lentisk* is a shrub or small tree, seldom more than twelve feet in height, much branched towards the top, and furnished with petiolate, abruptly pinnate leaves. The leaflets are from eight to twelve, and usually alternate, with the exception of the two upper, which are opposite. They are ovate-lanceolate, entire, obtuse, often mucronate, and sessile upon the common footstalk, which has a narrow foliaceous expansion on each side. The flowers are diœcious, and very small. The male are in an axillary ament; the female are arranged alternately upon a common peduncle, which is also axillary. The tree is a native of the countries bordering upon the Mediterranean. The fruit yields by expression a fixed oil, of a deep green color, and liquid at about 90° F., which the Arabs of North Africa use both as an article of diet and for light. A resinous exudation from the stem and branches is the official part, but it does not appear to be collected in all places where the tree flourishes.

Mastic is obtained chiefly from the island of Scio, or Chios, in the Grecian Archipelago, where the tree is cultivated for this product. Incisions are made in the trunk and principal branches, from which the juice slowly exudes, and either hardens in tears upon the bark, or drops on the ground, where it is received upon cloths or the bare earth, and concretes in irregular masses. The tears are most esteemed, and are the only form recognized by the U. S. P. They are of various sizes, oval or roundish, often compressed, smooth, semi-transparent, of a pale-yellow color, of a shining fracture, friable, and usually covered with a whitish powder, occasioned by their friction against each other. They are brittle, but become plastic when chewed. The masses consist of yellowish agglutinated tears, with others of a darker color and less translucent, and often fragments of wood, bark, or earthy matter intermingled.*

Mastic is nearly inodorous, unless rubbed or heated, when it becomes fragrant. Its taste is weak, but agreeably terebinthinate, and, after long chewing, very slightly acrid. It is at first friable under the teeth, but soon becomes soft and ductile, and acquires a white opaque appearance. Its sp. gr. is 1·074. It is fusible and inflammable by heat. Alcohol dissolves about 90 per cent. of it, leaving a viscid substance which becomes brittle when dried, and for which the name of *masticin* or *beta-resin of mastiche* has been proposed. This substance, though not dissolved by alcohol, softens and swells up in it, as gluten does in water. According to Ber-

* In a more recent account by M. J. Léon Soubeiran, it is stated that the juice is obtained not only by incision, but by spontaneous exudation from the branches, where it concretes in drops, which, after hardening, are gathered under the name of tears, which constitute the most valued part of the drug. But the greater part of the resin comes from longitudinal incisions in the stem, made with a knife, close together, and extending from the root to the branches. In fifteen or twenty days the resin has concreted, and is collected in little panniers of white paper or cotton cloth. Great care is taken to prevent it from falling on the ground and becoming soiled by the earth, and if any is thus soiled it is immediately cleansed at the time of collection. (*Journ. de Pharm.*, Nov.-Déc. 1870, 359. See also *Chem. and Drug.*, 1897, 273; also *Proc. A. P. A.*, 1897, 563.)

zelius, it possesses the same general properties as copal, and should be considered as a variety of resin. Hlasiwetz gives $C_{20}H_{31}O$ as the formula of the resin. The portion dissolved by the alcohol is called by Johnston *alpha resin of mastiche* or *mastichic acid* because of its acid properties, and has the formula $C_{20}H_{32}O_2$. (*Handwörterbuch der Chemie*, iv. p. 280.) Mastic is wholly soluble in ether, chloroform, and oil of turpentine, scarcely soluble in the fixed oils, and insoluble in water. It consists chiefly of resin, with *masticin*, and a volatile oil, which can scarcely be said to have been obtained in a separate state, though it imparts flavor to alcohol and water distilled from the mastic, especially when this has been previously triturated with an equal weight of potassium carbonate. Prof. Flückiger, through Schimmel & Co., of Leipsic, ascertained that this volatile oil is present in mastic to the extent of 2 per cent. He found it to be a terpene of the composition $C_{10}H_{16}$. Schimmel & Co. (*Semi-annual Report*, April, 1897) state that mastic resin yields from 0·9 to 2·5 per cent. of a powerful balsamic essential oil of the same order as the raw material, a sp. gr. of from 0·855 to 0·87 at 15° C., and an optical rotation (100-Mm. tube) of from +22° to +27°. Mastic is occasionally adulterated with olibanum, sandarach, and other resinous bodies, and, in seasons of scarcity, with sea-salt.

The present shipments from Chios are estimated at 30,000 kilos annually.

Medical Properties and Uses. Mastic was formerly thought to possess properties analogous to those of the turpentines, and was used in *debility of the stomach*, *hæmoptysis* from ulceration, *leucorrhœa*, *chronic diarrhœa*, etc.; but its virtues were overrated, and it is at present scarcely ever given internally. In the East, however, an aqueous infusion is said to be still used in infantile *cholera;* and the Greeks employ cataplasms made by mixing it with bread and red wine, which they apply to the lower abdomen. (*Landerer.*) It is sometimes employed to fill the cavities of carious teeth, for which purpose it is well fitted by its softness. Great quantities of it are consumed in Turkey, where it is habitually chewed by the women, under the impression that it sweetens the breath and preserves the gums and teeth. The alcoholic solution has been employed as a styptic in *bleeding from the nose*, *leech-bites*, etc., being applied by means of a camel's-hair pencil directly to the bleeding vessel. Dissolved in alcohol or oil of turpentine, it forms a brilliant varnish. A solution made by macerating half an ounce of mastic and fifteen grains of caoutchouc in two fluidounces of chloroform, and filtering in close vessels, forms a valuable *microscopic varnish*. The following mode of applying it to carious teeth has been recommended. Dissolve four parts of mastic in one of ether, in a bottle well stopped. With the solution thus formed, which is yellow and of an oily consistence, saturate a small piece of cotton of the size of the carious cavity, and, having well cleansed and dried the cavity, introduce the cotton, without painful pressure, so as to fill it exactly. The resin attaches itself to the diseased surface of the tooth, which it protects from the air, and from the food taken into the mouth.

MATICO. U. S. Matico.

(MĂT'Ī-CŌ.)

"The leaves of Piper angustifolium, Ruiz et Pavon (nat. ord. Piperaceæ)." *U. S.*

Matico Leaves; Feuilles de Matico, *Fr.;* Maticoblätter, *G.*

The genus Piper, according to Engler and Prantl, includes nearly six hundred species, which are distributed throughout the tropics of the Old and New World, being particularly numerous in tropical America and of relatively less number in Africa.

Piper angustifolium. Ruiz and Pavon, *Flor. Peruv.—Piper elongatum.* Vahl.—*Artanthe elongata.* Miquel; Lindley, *Med. and Œconom. Bot.* 133, fig. 195. This is a shrub with a jointed stem about twelve feet in height. In a dried specimen received from Dr. Ruschenberger, of the U. S. navy, the leaves are sessile or very shortly petiolate, oval-lanceolate, acuminate, from two to six inches long by about an inch in breadth, bright green on the upper surface, paler and downy beneath, finely crenate, tessellated above, reticulate beneath, the meshes small, and the veins densely brownish hairy; of an agreeable aromatic odor and a strong spicy taste. The spikes are solitary, opposite the leaves, and cylindrical. The bracts are peltate or cucullate; the flowers hermaphrodite. The plant is a native of Peru, where the fruit, under the name of Thoho-Thoho, is employed in the same manner as cubebs. This species is also found in other parts of South America. The commercial drug matico is furnished, according to G. Dethan and R. Bertault (*Journ. de Pharm. et de Chim.*, 1897, 537), by two varieties of *Piper angustifolium*,—viz., *α-cordulatum* (Artanthe elongata Miq.), and *β-ossanum*, which differ somewhat in the shape of the leaves. The former has the leaves larger, shorter, and broader, with an oblique cordate base. The midrib of *α-cordulatum* is much less convex below than in the

other variety. In 1864 Prof. Bentley (*P. J. Tr.*, Jan. 1864) described a false matico from Central America believed to be yielded by the *Artanthe aduncа*. It is distinguished by the want of the reticulations on the upper and the down on the under surface which characterize true matico.

The leaves, spikes, and stalks are mixed together, and more or less compressed, in the packages of the imported drug, and are all possessed of activity, though the leaves only are recognized by the Pharmacopœias. They are officially described as "from 10 to 15 Cm. long, short-petiolate, oblong-lanceolate, apex pointed, base unequally heart-shaped, margin very finely crenulate, tessellated above, reticulate beneath, the meshes small, and the veins densely brownish-hairy; aromatic, spicy, and bitterish." *U. S.* They are readily pulverized, forming a light, greenish, absorbent powder. According to Dr. Hodges, they contain chlorophyll, a soft dark-green resin, brown and yellow coloring matters, gum, salts, lignin, a light-green, thickish volatile oil, and a peculiar bitter principle, which he calls *maticin*, soluble in water and in alcohol, but not in ether. (*Philos. Mag.*, Sept. 1844, p. 206.) According to Mr. Wiegand, the maticin of Dr. Hodges is a salt of potassa. Mr. John J. Stell, who examined the drug in the expectation of discovering a principle analogous to cubebin or piperin, failed in the attempt. Flückiger found it to contain 2·7 per cent. of the volatile oil, which was slightly dextrogyre and boiling in large part at 180° C.–200° C. In winter-time it deposited large crystals of a camphor fusing at 103° C. and having the odor and taste of the oil. The crystals have the formula $C_{12}H_{20}O$ according to Kügler, and are perhaps the ethyl-derivative of ordinary camphor. (*Ber. d. Chem. Ges.* [16], p. 2841; also *A. J. P.*, 1884, p. 477.) Matico also affords, according to Marcotte, a crystallizable acid named *artanthic acid*, with some tannin. (*Pharmacographia*, Flückiger and Hanbury, 2d ed., p. 590.)

Medical Properties and Uses. Matico is an agreeable aromatic tonic and stimulant, having a tendency, like cubeb, to act on the urinary passages. It has long been known as a medicine in Peru. Dr. Martius speaks of its use by the natives externally as a vulnerary, and internally as an aphrodisiac (*Pharm. Centralb.*, 1843); and, according to Dr. Scrivener, who practised medicine at Lima, it is much employed in Peru locally for arresting *hemorrhage*, and in the treatment of *ulcers*. (*A. J. P.*, xviii.) In 1839 it was taken to England, and was prescribed by Dr. Jeffreys, of Liverpool, with advantage, in diseases of the mucous membranes, as *gonorrhœa*, *leucorrhœa*, *menorrhagia*, *catarrh of the bladder*, *hemorrhoids*, and *epistaxis*. Others have employed it with benefit in similar cases and in *diarrhœa;* and it is said to have proved useful in *hæmoptysis*, *hæmatemesis*, *dysentery*, and *hæmaturia*. Dr. Ruschenberger gives strong testimony in its favor in several of the diseases mentioned. Its most useful internal application is probably as an alterative stimulant to the diseased mucous membranes. If efficient as a hæmostatic, it must be on principles similar to those upon which oil of turpentine acts; for it is not astringent. As a local styptic it probably acts mechanically in the same manner as does agaric. The dose of the powder is from half a drachm to two drachms (1·95–7·8 Gm.) three times a day. The tincture and the fluid extract are official.

MATRICARIA. U. S. Matricaria. [German Chamomile.]

(MĂT-RĮ-CĀ'RĮ-Ą.)

"The flower-heads of Matricaria Chamomilla, Linné (nat. ord. Compositæ)." *U. S.*

Flores Chamomillæ Vulgaris, *P. G.;* Fleurs de Chamomille commune (d'Allemagne), *Fr.;* Kamille, Kamillenblumen, *G.*

Matricaria chamomilla. Linn. *Sp. Plant.* (1753) 891. This is an annual plant, with a branching stem a foot or two in height, bearing alternate leaves about two inches long, the lower ones tripinnate, the upper bipinnate or simply pinnate, and all of them very green, and nearly or quite smooth. The leaflets are linear and very small. The flowers appear singly at the ends of the stem and branches. They are about three-quarters of an inch in diameter, with the ray spreading. The bracts of the involucre are obtuse, green in the middle, and whitish, membranous, and translucent at the margin. The ray-florets are white, at first spreading, and ultimately reflected. The disk is of a deep yellow color, at first flat, but in the end convex, and even somewhat conical.

The plant is a native of Europe, and is occasionally cultivated in our gardens. All parts of it are active; but the flowers only are official. These shrink in drying, so that they are scarcely half as large as in their recent state. Those found in commerce are imported from Germany. They are officially described as "about 15 to 20 Mm. broad, composed of a flattish, imbricate involucre, a conical, hollow, naked receptacle, which is about 5 Mm. high, about fifteen white,

ligulate, reflexed ray-florets, and numerous yellow, tubular, perfect disk-florets without pappus; strongly aromatic and bitter. The similar flower-heads of *Anthemis arvensis* Linné, and *Maruta cotula* De Candolle (nat. ord. *Compositæ*), have conical, solid, and chaffy receptacles." *U. S.*

The dried flowers of the Matricaria are considerably smaller than those of common chamomile, and exhibit a larger proportion of the disk-florets compared with those of the ray. They have a strong, peculiar, rather unpleasant odor, and a disagreeable bitter taste. Their active constituents are volatile oil and bitter extractive, which are readily taken up by water and alcohol. The oil, which is obtained by distillation with water, is thick, somewhat tenacious, of a fine deep blue color becoming green and brown by age, and almost opaque in mass. Though supposed by Gerhardt to be identical with the oil of chamomile (*Anthemis nobilis*), it has been shown to be distinct. (*P. J. Tr.*, Feb. 1862, p. 429.) It congeals at —4° F., has the sp. gr. 0·93, and contains a terpene, $C_{10}H_{16}$, and a colorless oil, $C_{10}H_{16}O$. *Schimmel & Co.'s Report* for April, 1897, states that the German chamomile oil contains a paraffin hydrocarbon. The blue color is due to a volatile principle called *azulene* by Piesse, and *cærulein* by Gladstone and others. This, when distilled with potassium, yields a terpene, $(C_{10}H_{16})_3$, and with phosphoric oxide a hydrocarbon, $C_{10}H_{14}$. (Kachler, *Ber. d. Chem. Ges.*, iv. 36.)

Medical Properties and Uses. Matricaria is a mild tonic, very similar to chamomile in medical properties, and, like it, in very large doses an emetic. It is considered also in Europe to be antispasmodic and anthelmintic. It is much employed in Germany, but in this country scarcely at all, unless by German practitioners. It may be given for the same purposes and in the same manner as chamomile.

MEL. U. S. Honey.

(MĔL.)

"A saccharine secretion deposited in the honey-comb by Apis mellifica, Linné (class, Insecta; order, Hymenoptera)." *U. S.*

Miel, *Fr.;* Honig, *G.;* Miele, *It.;* Miel, *Sp.*

Naturalists have not yet determined whether honey is a secretion of the bee, *Apis mellifica*, or exists already formed in plants. It is certain that the nectaries of flowers contain a saccharine matter, which is extracted by the insect; and the fact is well known that the flavor and character of honey are very much affected by the nature of the plants which predominate in the vicinity of the hive,—so much so that when these plants are poisonous the fluid sometimes partakes of their noxious qualities. Several cases of poisoning from eating honey from a particular source are recorded in the *New Jersey Medical Reporter* for November, 1852, p. 46.* Still, it probably undergoes change in the organs of the bee, as the saccharine matter of the nectaries, so far as it has been possible to examine it, lacks some of the characteristic properties of honey.† The finest honey is that which is allowed to drain from the comb. If obtained from hives that have never swarmed, it is called *virgin honey*. An inferior kind is procured by submitting the comb to pressure; and if heat be employed previous to expression, the product is still more impure.

In the recent state honey is fluid; but on being kept it is apt to form a crystalline deposit, and to be ultimately converted into a soft granular mass. In commerce it is found of every

* H. Bley states that poisonous honey is sometimes imported into Europe from Trebizond, and also from America, and attributes the toxic properties to the bees feeding upon *Datura stramonium* and *Gelsemium*. (*Pharm. Zeit.*, Nov. 1885.) For an interesting paper on "Poisonous Honey," by L. F. Kebler, see *Proc. A. P. A.*, 1896, 167.

† *Propolis.* This is a resinous substance, deposited by bees at the base of the hive, and in other parts which require protection from the outer air, of a nature entirely different from that of wax or honey, and supposed to be intended for the protection of the comb from injurious external agencies. Dr. H. O. Hitchcock (*Chicago Med. Journ.*, 1867) considers it one of the best remedies in simple mucous *diarrhœa*, even when severe and attended with pain and vomiting. In many cases only a single dose is required. It appears to possess anodyne and soporific properties. He has found it also efficacious in *dysentery* in the early stage; but it has proved useless in the disease when fully established. In *chronic diarrhœa*, even of the kind contracted in camp and remarkable for its obstinacy, it has seemed to act like a charm. It is of a dark reddish or yellowish-brown color, of a shining fracture, an aromatic taste and smell, quite insoluble in water, nearly so in ether, but readily dissolved by alcohol and solution of potassa. Dr. Hitchcock has used both a tincture and an alkaline solution; the former (two drachms of propolis and four fluidounces of alcohol) in doses of from thirty minims to a fluidrachm (1·9–3·75 C.c.); the latter (two drachms of the resin to a fluidrachm of liquor potassæ and four fluidounces of a menstruum consisting of equal parts of water and simple syrup) in the dose of half a fluidrachm (1·9 C.c.) after each stool.

Bee-bread is the name given to a material found in some of the cells of the comb, consisting mainly of the pollen of plants. (*Chicago Med. Examiner*, Sept. 1865.) Dr. Jas. S. Whitmire found that in the dose of a drachm (3·9 Gm.) three times a day it caused great increase of the urinary secretion. No disagreeable effects followed its use, except a slight flatulency and looseness of the bowels. It is entirely palatable and inoffensive to the stomach. (*A. J. P.*, 1866.)

Eucalyptus Honey, or Black Honey. This honey, a detailed description of which may be found in U. S. D., 16th ed., appears to have been not a natural but a sophisticated article.

consistence, from that of a viscid liquid like thin syrup or oil, to that of lard or soft suet. Its color is sometimes white, but usually yellowish, and occasionally of a brownish or reddish tinge. It has a peculiar agreeable odor, varying somewhat with the flowers from which it was collected, and a very sweet, feebly aromatic taste, which is followed by a slight prickling or sense of acrimony in the fauces. Its sp. gr. is about 1·333. (*Duncan.*) Cold water dissolves it readily, alcohol with less facility. "A syrupy liquid of a light yellowish to pale yellowish-brown color, translucent when fresh, but gradually becoming opaque and crystalline, having a characteristic, aromatic odor, and a sweet, faintly acrid taste. When recent Honey is diluted with 2 parts of water, the resulting liquid should be almost clear, not stringy, and should have a specific gravity not lower than 1·100 (corresponding to a specific gravity of 1·375 for the original Honey). Honey has a faintly acid reaction towards litmus paper. If 1 part of Honey be dissolved in 4 parts of water, a clear or nearly clear solution will result, which should not be rendered more than faintly opalescent by a few drops of silver nitrate test-solution (limit of *chlorides*), or of barium chloride test-solution (limit of *sulphates*). If 1 volume of Honey be diluted with 1 volume of water, and a portion of this liquid gradually mixed with 5 volumes of absolute alcohol, it should not become more than faintly opalescent (as compared with the reserved portion of the solution), and should neither become opaque, nor deposit a slimy substance on the inner walls and bottom of the test-tube. And when Honey is incinerated, in small portions at a time, in a platinum crucible, it should not leave more than 0·2 per cent. of ash (absence of *glucose* and *foreign inorganic substances*). On boiling 1 part of Honey with 5 parts of water, the resulting solution, when cold, should not be rendered blue or green on the addition of iodine test-solution (absence of *starch*)." *U. S.* It is essentially a strong aqueous solution of mixed dextrose and levulose, the mixture being known as "glucose," and amounting generally to from 70 to 80 per cent.

The following analyses of pure, unadulterated honey show the variations in its composition. They were made by Dr. J. Campbell Brown (*Analyst*, iii. 269).

Locality.	Levulose.	Dextrose.	Sucrose.	Wax, Pollen, and Insoluble Matter.	Ash.	Water expelled at 100° C.	Water expelled above 100° C. and Loss.

The glucose may be obtained by treating granular honey with a small quantity of alcohol, which, when expressed, takes along with it the other ingredients, leaving the crystals nearly untouched. The same end may be obtained by melting the honey, saturating its acid with calcium carbonate, filtering the liquid, then setting it aside to crystallize, and washing the crystals with alcohol. Inferior honey usually contains a large proportion of uncrystallizable sugar and vegetable acid. Diluted with water, honey undergoes the vinous fermentation. In warm weather, honey itself, if not very pure, sometimes ferments, acquiring a pungent taste and deeper color.* The presence of dextrin in pure honey seems to be established. G. L. Spencer (*A. J. P.*, 1895, 27) has found as much as 4 per cent. of dextrin, and Haenle (*Zeits. Anal. Chem.*, 94, 99) has shown that honey from Coniferæ always contains dextrin. Künnmann and Hilger (*A. J. P.*, 1896, 570) state that dextrin is present in all honey, whether dextrorotatory or lævo-rotatory, and claim to have identified it as achroo-dextrin. Starch is said to be occasionally added to the inferior kinds to give them a white appearance. The adulteration may be detected by adding water, which dissolves the honey and leaves the starch at the

* Dr. Müllenhoff believes that the honey is preserved in the sealed cells of the comb by the secretion with it of a minute quantity of formic acid, and has found by experiment that the addition of one part of 25-per-cent. formic acid is sufficient to keep permanently 250 parts of honey; but in this connection it should be remembered that the absence of contact with the air would account for the preservation of honey in the comb.

bottom of the vessel. Dilution with water may be suspected from the greater thinness of the honey and its want of disposition to crystallize.

Honey is largely adulterated with artificial glucose. This may be detected by the official tests, but the safest method is to determine the sugar by the use of Fehling's solution. The grape sugar may be determined directly in a weighed quantity of honey. An equal weight of the same honey is boiled with 2-per-cent. sulphuric acid, and the sugar may be determined after inversion; finally the dextrin may be determined in a third portion by precipitation with alcohol. The difference in the quantity of sugar found before and after inversion is so great as to furnish a certain method for distinguishing natural and artificial honey. According to Oscar Haenle, glucose can also be detected by first dialysing thoroughly and then polarizing, under which circumstance, if glucose be present, rotation to the right occurs; if the honey be pure the light is not affected. Undialysed honey ordinarily polarizes to the left, but unadulterated conifer-honeys are dextrogyre. (*P. J. Tr.*, xxi.)

Medical Properties and Uses. Honey possesses the same medical properties as sugar, but is more disposed to affect the bowels. Though largely consumed as an article of food, it is seldom employed medicinally, except as a vehicle. Its taste and demulcent qualities render it a useful addition to gargles; and it is sometimes employed as an application to *foul ulcers.*

MEL BORACIS. Br. Borax Honey.

(MĔL BO-RĀ'CĬS.)

Mel Sodii Boratis, *U. S.* 1870; **Honey of Borax, Honey of Borate of Sodium; Miel boraté, Mellite de Borax,** *Fr.;* **Boraxhonig,** *G.*

"Borax, in fine powder, 1 *ounce* (Imperial) or 50 grammes; Glycerin ½ *ounce* (Imp.) or 25 grammes; Clarified Honey, 8 *ounces* (Imp.) or 400 grammes. Mix." *Br.*

This preparation was very properly dropped from the U. S. Pharmacopœia at the 1880 revision, as it may well be left to extemporaneous prescription. The U. S. formula of 1870 was practically identical with the British process given above. Borax honey is used in the thrush of infants and in aphthous ulcerations of the mouth.

MEL DESPUMATUM. U. S. (Br.) Clarified Honey.

(MĔL DĔS-PŪ-MĀ-TŬM.)

"Honey of commerce, melted in a water-bath, and strained, while hot, through flannel previously moistened with warm water." *Br.*

Mel Depuratum, *Br.;* **Miel déspumé, Mellite simple,** *Fr.;* **Gereinigter Honig,** *G.*

"Honey, *a convenient quantity;* Glycerin, *a sufficient quantity.* Mix the Honey intimately with *two per cent.* of its weight of paper-pulp, which has been previously reduced to shreds, thoroughly washed and soaked in water, and then strongly expressed and again shredded. Then apply the heat of a water-bath, and, as long as any scum rises to the surface, carefully remove this. Finally, add enough Distilled Water to make up the loss incurred by evaporation, strain, and mix the strained liquid with *five per cent.* of its weight of glycerin." *U. S.*

The U. S. 1890 method of clarifying honey is new as far as the Pharmacopœia is concerned: paper-pulp is very effective as a clarifying agent, and the glycerin offers some protection to the honey against change. Honey may be made brilliant by hot filtration through paper. (See Remington's *Practice of Pharmacy*, "Hot Filtration," p. 217.)

Honey, by the heat of the water-bath, becomes so fluid that the wax and other lighter impurities which it contains rise to the surface and may be skimmed off; while the heavier substances which may have been accidentally or fraudulently added, such as sand or other earth, sink to the bottom. A neat method of separating is described in *N. R.*, Feb. 1880. It is as follows. "Pour the honey into a perfectly clean cylindrical vessel, with straight sides, rather narrow, and having a small lip at the open margin, and heat the vessel on a water-bath. When the water is hot, pour enough honey into the vessel to fill it to within about 1 inch of the edge, and allow it to remain at rest in the water-bath, at a moderate heat, for about one hour. During this time, most of the impurities will rise to the top, while some others may sink to the bottom. Now remove the vessel very carefully from the water-bath, and pour on top of the hot honey, very gently, a sufficient amount of cold water to fill the vessel completely. This will cause all the impurities floating on the honey at once to rise to the top of the cold water, where they will often solidify to a tough skin or cake, which may be taken off without difficulty. Then pour off the water through the lip, remove the last remnants, if necessary, by means of blotting-paper, and filter the honey through a piece of well-washed, wetted, and

dense white flannel. The resulting product—if the honey be pure—will be very brilliant." The French Codex simply directs six pounds of white honey to be heated with two pounds of water, skimmed, concentrated to 30° B. while boiling hot, and then strained through flannel. The British Pharmacopœia describes it as " A viscid translucent liquid of a light-yellowish or brownish-yellow color, gradually becoming partially crystalline and opaque. It has a characteristic odor and very sweet taste. Incinerated it should not yield more than 0·25 per cent. of ash, the solution of which in *water* acidulated with *nitric acid* should not afford more than a slight turbidity with *solution of barium chloride* (absence of more than traces of sulphates). It should yield no characteristic reaction with the iodine test for starch."

The following method of clarifying honey is recommended by André von Hirschberg. Boil 25 pounds of honey, to which half the quantity of water has been added, with a pulp obtained by stirring three sheets of white blotting-paper with water, over a slow fire, till the paper is reduced to minute fibres. When the mixture cools, put it into a woollen filtering bag, previously moistened, and allow the honey to pass. It comes away quite clear. The pulp may then be washed, and the dark liquid evaporated by a water-bath to the proper consistence. (*P. J. Tr.*, ix.) Another process, recommended by A. Hofmann, is to dissolve 28 pounds of honey in twice its weight of water, heat the solution to the boiling point, and then add a solution of three drachms of gelatin in three times its weight of water, and afterwards an aqueous solution of one drachm of tannin, or an infusion of two drachms of galls. The mixture is to be well stirred, and kept hot for an hour. Lastly, seven-eighths of the honey may be drawn off clear, the remainder filtered through flannel, and the whole evaporated. (*Ibid.*, xv. 121.) The use of tannin is objectionable, however, on account of its solubility in honey, and the danger of honey so purified reacting when brought in contact with ferric salts. For other processes of purifying honey, see 14th edition of this work, p. 1321, and *A. J. P.*, 1877, p. 19; also 1879, pp. 193, 598, and 1880, p. 132. Heugel's method is to mix two pounds each of honey and water with a half-ounce of magnesium carbonate, frequently agitate for two or three hours, filter through doubled white filtering-paper, boil slowly, remove the scum carefully, and evaporate upon a steam-bath to a syrupy consistence.

Honey clarified with calcium carbonate and animal charcoal, or as in the first process described, is as clear and colorless as syrup made with sugar, but still retains a peculiar flavor. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

MEL ROSÆ. U. S. Honey of Rose.

(MĔL RŌ′ṢÆ.)

Mel Rosatum, *P. G.;* Mellitum Rosatum; Mellite de Roses rouges, Miel Rosat, *Fr.;* Rosenhonig, *G.*

" Fluid Extract of Rose, *one hundred and twenty cubic centimeters* [or 4 fluidounces, 27 minims]; Clarified Honey, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains. Into a tared vessel introduce the Fluid Extract of Rose, then add enough Clarified Honey to make the contents weigh *one thousand grammes* [or 35 ounces av., 120 grains], and mix them thoroughly." *U. S.*

Though one of the officials in the late London and Edinburgh Pharmacopœias, the Honey of Rose has been dropped in the British. The U. S. formula is based on that of Prof. Grahame. (See *A. J. P.*, 1859, p. 443.) Honey of rose forms a pleasant addition to the gargles employed in *inflammation* and *ulceration* of the *mouth and throat.*

MELISSA. U. S. Melissa. [Balm.]

(MĘ-LĬS′ṢA.)

" The leaves and tops of Melissa officinalis, Linné (nat. ord. Labiatæ)." *U. S.*

Folia Melissæ, *P. G.;* Herba Melissæ; Lemon Balm; Herbe au Citron, Mélisse, *Fr.;* Melissenblätter, Citronenkraut, Garten-Melisse, *G.;* Melissa, *It.;* Torongil, *Sp.*

Melissa officinalis. L. *Sp. Pl.* (1753) 592; Willd. *Sp. Plant.* iii. 146; Woodv. *Med. Bot.*, 334, t. 119. Balm has a perennial root, which sends up annually several erect quadrangular stems, usually branched towards the base, and a foot or two in height. The leaves are about two inches long, are opposite, ovate or cordate, obtuse, deeply serrate, glandular or pubescent; the lower on long footstalks, the uppermost nearly sessile. The flowers are white or yellowish, upon short peduncles, and in axillary whorls of four or five, surrounding only half the stem. The calyx is tubular, pentangular, and bilabiate, with the upper lip tridentate and flattened, the lower cut into two pointed teeth. The corolla is whitish or purplish, tubular and bilabiate, the upper lip less convex and notched, the lower three-cleft. The plant is a native of the

south of Europe. It has been introduced into this country, where it is cultivated in gardens and grows wild along the fences of our roads and lanes. For use the herb should be cut before the appearance of the flowers, which begin to expand in July. In the fresh state it has a fragrant, lemon-like odor, but it is nearly inodorous when dried. The taste is somewhat austere, and slightly aromatic. The herb contains a minute proportion of a yellowish, highly flavored essential oil; also tannin, bitter extractive, and gum.

Medical Properties and Uses. Balm produces scarcely any remedial effects upon the system. The quantity of oil which it contains is not more than sufficient to communicate an agreable flavor to the infusion, which forms an excellent drink in febrile complaints, and when taken warm tends to promote the operation of diaphoretic medicines.

MENISPERMUM. U. S. Menispermum. [Yellow Parilla. Canadian Moonseed.]

(MĔN-Ĭ-SPĔR'MŬM.)

"The rhizome and roots of Menispermum Canadense, Linné (nat. ord. Menispermaceæ)." *U. S.*

M. canadense. L. This is a woody, climbing plant, which grows throughout Eastern North America. It is specifically characterized by its peltate three- to seven-lobed leaves, its small clusters of greenish-yellow flowers, and its somewhat kidney-shaped glaucous fruit, which is ripened in the month of September. Its root was first brought into market as *Texas Sarsaparilla*, and identified by Prof. Robt. P. Thomas. (*A. J. P.*, xxvii. 7.) There are but two other species of Menispermum known,—viz., *M. dahuricum* D. C., in Central and Eastern Asia, and *M. diversifolium* (Cocculus Miq.) Prantl, in Japan.

Properties. Menispermum is officially described as follows: "Rhizome several feet long, 5 Mm. thick, brown or yellowish-brown, somewhat knotty, finely wrinkled longitudinally and beset with numerous thin, rather brittle roots; fracture tough, woody; internally yellowish, the bark rather thick, the wood-rays broad, porous, and longest on the lower side; pith distinct. Nearly inodorous; taste bitter." *U. S.* Prof. J. M. Maisch proved the presence of a white alkaloid, and of a small quantity of berberine. The former reacts with the usual alkaloidal precipitants, is not very soluble in water, but soluble in alcohol and ether. H. L. Barber (*A. J. P.*, 1884, p. 401) obtained the white amorphous alkaloid above referred to, for which Prof. Maisch proposed the name *menispine*. He gives, moreover, a comparison of the properties of this alkaloid with those of menispermine and oxyacanthine. Starch was also found in the root. (*A. J. P.*, 1863, p. 301.)

Medical Properties. In an unpublished inaugural dissertation by Dr. George F. Terrell (Feb. 1844), it is stated that the root of this plant is considerably employed in Virginia, both in domestic practice and by physicians, as a substitute for sarsaparilla in *scrofulous affections*. It is also reputed to be tonic, but is very rarely used in regular practice, and is probably inert.

MENTHA PIPERITA. U. S. Peppermint.

(MĔN'THĄ PĪ-PĔ-RĪ'TĄ.)

"The leaves and tops of Mentha piperita, Smith (nat. ord. Labiatæ)." *U. S.*

Folia (Herba) Menthæ Piperitæ, *P. G.;* Menthe poivrée, *Fr.;* Pfefferminze, Pfeffermünze, *G.;* Menta piperita, *It.;* Pimenta piperita, *Sp.*

The genus Mentha comprises at least fifteen species, of which there are also a great many varieties. *M. piperita*,—L. (1753), also Smith (1800),—the most important member of this genus, was long ago cultivated by the Egyptians, and is now grown in considerable amounts in Europe, North America, and Eastern Asia. It is also found growing wild in other parts of the world, as South America and Australia. The oldest existing peppermint district is in the neighborhood of Mitcham (Surrey), England. In some parts of the United States, especially in Michigan, the western part of New York, Ohio, and Indiana, it is largely cultivated.* On the continent of Europe other species of Mentha (particularly *M. arvensis*) grow with *M. piperita*, deteriorating the product. In America other plants (as *Erigeron canadense* and *Erechthites hieracifolia*) cause the same trouble. Besides *M. piperita* other species are cultivated, as some Asiatic varieties of *M. arvensis*, *M. viridis*, *M. longifolia* (var. *undulata*), *M. gentilis*, *M. dalmatica*, and *M. pulegium*.

Mentha piperita. L. *Sp. Pl.* (1753) 576; Willd. *Sp. Plant.* iii. 79; *B. & T.* 203; Carson, *Illust. of Med. Bot.*, ii. 16, pl. 63. Peppermint is a perennial herbaceous plant, with a creeping

* For an interesting account of the distribution of the peppermint culture in the United States and the amount of oil produced in 1897, see *Schimmel & Co.'s Report* for October, 1897, 40.

root, and quadrangular, channelled, purplish, somewhat hairy stems, branched towards the top, and about two feet in height. The leaves are about two inches long, opposite, petiolate, ovate, serrate, pointed, smoother on the upper than on the under surface, and of a dark green color, which is paler beneath. The flowers are small, purple, and in terminal obtuse spikes, interrupted below, and cymosely arranged. Late in the season, the growth of the lateral lower branches often gives to the inflorescence the appearance of a corymb. The calyx is tubular, furrowed, and five-toothed, often purplish; the corolla is purplish, tubular, with its border divided into four segments, of which the uppermost is broadest, and notched at its apex. The four short stamens are concealed within the tube of the corolla; the style projects beyond it, and terminates in a bifid stigma. The plant should be cut for medical use in dry weather, in August, about the period of the expansion of the flowers. John C. Umney points out differences between white and black peppermint in *P. J. Tr.*, 1896, 123.

Peppermint leaf. 1, epidermis of the upper side, showing gland and hair; 2, epidermis of the under side, showing stomata, gland, and hair.

The herb, both in the recent and in the dried state, has a peculiar, penetrating, grateful odor. There is sometimes difficulty in distinguishing between the leaves of *M. piperita* and those of *M. viridis*. According to Joseph Schrenk, crystals can always be found in the glandular hairs of the peppermint, but are absent in those of the spearmint. The crystals are doubly refractive, and so transparent that sometimes a polariscope is necessary for their easy detection. These crystals have been thought to be menthol, but they seem not to dissolve in alcohol, and their nature remains doubtful. The taste of the herb is aromatic, warm, pungent, camphorous, bitterish, and attended with a sensation of coolness when air is admitted into the mouth. These properties depend on a volatile oil, of which from 1 to 1·25 per cent. can be obtained from the herb. The leaves are said to contain a little tannic acid. The virtues of the herb are imparted to water, and more readily to alcohol.

Medical Properties and Uses. Peppermint is a grateful aromatic stimulant, much used for all the purposes to which medicines of this class are applied. To allay *nausea*, relieve *spasmodic pains of the stomach and bowels*, expel *flatus*, and cover the taste or qualify the nauseating or griping effects of other medicines, are among the most common of these purposes. The fresh herb, bruised and applied to the epigastrium, often allays *sick stomach*, and is useful in the *cholera of children*. The medicine may be given in infusion; but the volatile oil, either alone or in some state of preparation, is generally preferred. (See *Oleum Menthæ Piperitæ.*)

MENTHA VIRIDIS. U. S. Spearmint.

(MĔN'THA VĬR'Ĭ-DĬS.)

"The leaves and tops of Mentha viridis, Linné (nat. ord. Labiatæ)." *U. S.*

Herba Menthæ Acutæ (vel Romanæ); Menthe verte, Menthe romaine, Baume vert, Menthe à épi, *Fr.;* Grüne Münze, Römische Minze, *G.;* Menta Romana, *It.;* Yerba buena puntiaguda, *Sp.*

Mentha viridis. L. *Sp. Pl.* (1753) 804; Willd. *Sp. Plant.* iii. 76; *B. & T.* 302; *M. spicata*, L. (1753); *M. spicata*, var. *viridis*, L. (1753). Spearmint, sometimes called simply *mint*, differs from *M. piperita* chiefly in having sessile or nearly sessile, lanceolate, naked leaves; elongated, interrupted, panicled spikes; setaceous bracts; and stamens longer than the tube of the corolla. It is a native of Europe and Asia, and naturalized in waste places from Nova Scotia and Ontario to Minnesota and Kansas in the West and Florida in the South United States. It is also cultivated for domestic use and for the sake of its oil. Its flowering season is August. According to Thomson, it should be cut in very dry weather, and, if intended for medical use, just as the flowers appear; if for obtaining the oil, after they have expanded.

The odor of spearmint is strong and aromatic, the taste warm and slightly bitter, less pungent than that of peppermint, but considered by some to be more agreeable. These properties are retained for some time by the dried plant. They depend on a volatile oil, which is obtained by distillation, and is imparted to alcohol and water by maceration. (See *Oleum Menthæ Viridis.*) The virtues and applications of this plant are the same as those of peppermint.

MENTHOL. U. S., Br.

$C_{10}H_{19}OH$; 155·66. (MĔN'THŎL.) $C_{10}H_{20}O$.

"A stearopten (having the character of a secondary alcohol), obtained from the official oil of peppermint (from Mentha piperita, Smith), or from Japanese or Chinese oil of peppermint

(from Mentha arvensis, Linné, var. piperascens, Holmes, and Mentha canadensis, Linné, var. glabrata, Holmes; nat. ord. Labiatæ). Menthol should be kept in well-stoppered bottles, in a cool place." *U. S.* "A crystalline substance, C_6H_9 OH.CH_3.C_3H_7, obtained by cooling the oil distilled from the fresh herb of Mentha arvensis, DC., vars. piperascens et glabrata, Holmes; and of Mentha piperita, Sm." *Br.*

This substance was admitted to the British Pharmacopœia of 1885, and is one of the new officials of the U. S. P. 1890. Menthol, or *peppermint camphor*, may be obtained from either American or Japanese oil of peppermint by cooling the oil to a very low temperature, when the menthol crystallizes out, often in a dense mass; the adhering oil may be separated by expression. Menthol may also be obtained by fractional distillation, and there is reason to believe that the oil of peppermint of commerce is often contaminated with the dementholized oil. A larger yield of menthol is obtained from Japanese or Chinese oils, and for this reason Japanese menthol is largely found in commerce. It is practically identical with American menthol, differing, however, in the character of its crystals, which occur in small prisms instead of in long needles.

The U. S. P. 1890 describes it as follows: "Colorless, acicular or prismatic crystals, having a strong and pure odor of peppermint, and a warm, aromatic taste, followed by a sensation of cold, when air is drawn into the mouth. Menthol is only slightly soluble in water, but imparts to the latter its odor and taste. It is freely soluble in alcohol, ether, chloroform, carbon disulphide, or glacial acetic acid. It melts at 43° C. (109·4° F.) to a colorless liquid, boils at 212° C. (413·6° F.), and volatilizes slowly at the ordinary temperature. When it is triturated with about an equal weight of camphor, thymol, or chloral hydrate, the mixture becomes liquid. Its alcoholic solution is neutral to litmus paper, and deviates polarized light to the left. If a little Menthol be heated in an open capsule, on a water-bath, it should gradually volatilize without leaving any residue (absence of *wax*, *paraffin*, or *inorganic substances*). If a few crystals of Menthol be dissolved in 1 C.c. of glacial acetic acid, and then 3 drops of sulphuric acid and 1 drop of nitric acid added, no green color should be produced (absence of *thymol*)." "Melting point 107·6° F. (42° C.); it should not exceed 109·4° F. (43° C.). It has the odor and flavor of peppermint, producing a sensation of warmth on the tongue, and, if air is inhaled, a sensation of coolness. It is very slightly soluble in *water*, but readily soluble in *alcohol* (90 per cent.), the solutions having a neutral reaction. Boiled with *sulphuric acid* diluted with half its volume of *water*, Menthol acquires an indigo-blue or ultramarine color, the acid becoming brown. It should be entirely volatilized by the heat of a water-bath." *Br.*

Menthol belongs to the class of camphors. Its formula may be written $C_{10}H_{19}OH$, as it is recognized as being a saturated secondary alcohol. Chromic acid oxidizes menthol to *dextro-* and *lævo-menthone*, $C_{10}H_{18}O$, which is the ketone corresponding. The *menthones* are liquids, with an odor resembling that of peppermint. They boil at 207° C. Distillation with zinc chloride or phosphoric anhydride changes menthol into liquid *menthene*, $C_{10}H_{18}$, boiling at 167° C. (See papers by Kremers, Urban, and Richtmann on the menthol group, *Proc. A. P. A.*, 1893, 185; also 1896, 200.) Menthol has been grossly adulterated with spermaceti, paraffin, etc., and, after being compressed into pencils or cones, sold as a local panacea for headache and neuralgia.

Medical Properties and Uses. According to the experiments of Pellacani, menthol in sufficient dose, taken internally, is capable of paralyzing the spinal nerve-centres, and also the nerve-trunks, destroying both motility and sensibility. It has not been used in internal medicine, although the British Pharmacopœia gives the dose of it as from one and one-half to two grains, but it is very largely employed as a local anæsthetic application for the relief of *neuralgic pains*, *toothache*, *sciatica*, etc. When it is applied in solid form to the skin it produces a burning pain, associated with a sensation of cold and some benumbing of the skin, and it is chiefly used in the shape of cones without dilution. In this way it has had a very wide popularity in the treatment of headache, *neuralgia*, and superficial pains of various character, but is at present not so much used as formerly. According to Dr. S. A. Russel, an ethereal solution of the strength of from 10 to 50 per cent. applied two or three times a day has a remarkable power of controlling superficial inflammations, such as *boils*, *carbuncles*, etc. Its solution (from two to ten grains in a fluidounce of water) is said to be effective in *pruritus ani*, *chronic painful eczemas*, *urticaria*, etc. It is also largely used as a local remedy in the treatment of inflammations about the mouth, such as *stomatitis*, *angina*, *tonsillitis*, etc., either in dilute watery solution, two grains to the fluidounce, or, preferably, in troches.

METHYL SALICYLAS. U. S. Methyl Salicylate. [Artificial (or Synthetic) Oil of Wintergreen.]

$CH_3C_7H_5O_3$; 151·64. (MĒ′THĬL SĂL-Ĭ-CĪ′LĂS.)

"Methyl Salicylate, produced synthetically. It should be kept in well-stoppered bottles, protected from light." *U. S.*

Methyl salicylate, or artificial oil of wintergreen, has been introduced into the U. S. P. 1890 largely because of its extensive use and on account of its being a manufactured product: it is asserted that it can be produced of more uniform quality and is more definite and certain in its action than either the oil from gaultheria or the oil from birch, which are natural oils. (See *A. J. P.*, 1889, p. 398; *Pharm. Rundschau*, 1889, 283; see, also, 1892, 7–9.) Methyl salicylate may be made by distilling salicylic acid, or a salicylate, with methyl alcohol and strong sulphuric acid. The following process was devised by G. M. Beringer, *A. J. P.*, 1887, p. 8. Dissolve half an ounce of salicylic acid in two fluidounces of absolute methylic alcohol, then gradually add one fluidounce of sulphuric acid; warm gently for twenty-four hours, then distil from a retort into which a current of steam is introduced. The distillate is to be well washed, and separated by decantation. The odor improves with age. Methyl salicylate has been found in a great number of plants. (See *A. J. P.*, 1898, 412.)

Properties. Methyl salicylate is officially described as "a colorless or slightly yellowish liquid, having the characteristic, strongly aromatic odor and the sweetish, warm, and aromatic taste of Oil of Gaultheria, with the essential constituent of which it is identical. It is wholly identical with Volatile Oil of Betula (see *Oleum Betulæ Volatile*). Specific gravity, 1·183–1·185 at 15° C. (59° F.). Boiling point: 219°–221° C. (426·2°–429·8° F.). It is optically inactive. Soluble, in all proportions, in alcohol, glacial acetic acid, or carbon disulphide. The alcoholic solution is neutral or slightly acid to litmus paper. If a drop of Methyl Salicylate be shaken with a little water, and a drop of ferric chloride test-solution subsequently added, a deep violet color will be produced. When heated on a water-bath, in a flask provided with a suitable condenser, it should yield no distillate having the characteristics of *alcohol* or *chloroform*. If to 1 C.c. of Methyl Salicylate, contained in a capacious test-tube, 10 C.c. of sodium hydrate test-solution be added, and the mixture agitated, a bulky, white, crystalline precipitate will be produced; then, if the test-tube, loosely corked, be allowed to stand in boiling water for about five minutes, with occasional agitation, the precipitate should dissolve, and form a clear, colorless or faintly yellowish solution, without the separation of any oily drops, either on the surface or at the bottom of the liquid (absence of *other volatile oils*, or of *petroleum*). If the alkaline liquid thus obtained be subsequently diluted with about three times its volume of water, and a slight excess of hydrochloric acid added, a white crystalline precipitate will be produced which, when collected on a filter, washed with a little water, and recrystallized from hot water, should respond to the tests of identity and purity described under *Acidum Salicylicum* (absence of *methyl benzoate*, etc.)." *U. S.*

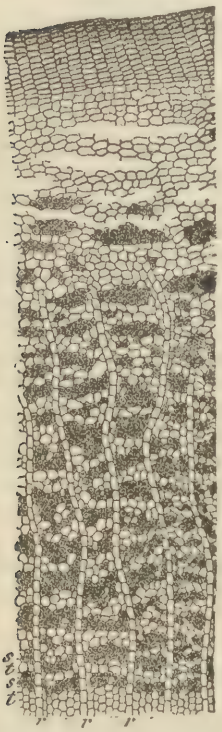
Medical Properties and Uses. So far as is known, the physiological and remedial properties of the artificial oil of gaultheria do not differ from those of the natural product. (See *Oleum Gaultheriæ*.)

MEZEREUM. U. S. (Br.) Mezereum.

(MĒ-ZĒ′RĒ-ŬM.)

"The bark of Daphne Mezereum, Linné, and of other species of Daphne (nat. ord. Thymelaceæ)." *U. S.* "The dried bark of Daphne Mezereum, Linn., or of Daphne Laureola, Linn., or of Daphne Gnidium, Linn." *Br.*

Mezerei Cortex, *Br.*, Mezereon Bark; Cortex Mezerei, *P. G.;* Cortex Thymeleæ (vel Coccognidii); Ecorce de Mézéréon de Garou, de Lauréole, de Thymélée, Bois gentil, *Fr.;* Kellerhals, Seidelbastrinde, Kellerhalsrinde, *G.;* Mezereo, *It.;* Mecereon, *Sp.*



All the species of Daphne are possessed of active properties; but three only are official,—*D. mezereum*, *D. laureola*, and *D. gnidium*, all of which are recognized in the British Pharmacopœia, only the last in the French Codex.

1. *Daphne mezereum.* L. *Sp. Pl.* (1753) 356; Willd. *Sp. Plant.* ii. 415; *B. & T.* 225; Carson, *Illust. of Med. Bot.*, ii. 26, pl. 72. This is a very hardy shrub, three or four feet high, with a branching stem, and a smooth, dark gray bark, very easily separable from the wood. The leaves spring from the ends of the branches, are deciduous, sessile, obovate-lanceolate, entire, smooth, of a pale green color, somewhat glaucous beneath, and about two inches long. They are preceded by the flowers, which appear very early in spring, and sometimes bloom

even amidst the snow. These are of a pale rose color, highly fragrant, and disposed in clusters, each consisting of two or three flowers, forming together a kind of spike at the upper part of the stem and branches. At the base of each cluster are deciduous floral leaves. The fruit is oval, shining, fleshy, of a bright red color, and contains a single round seed. Another variety produces white flowers and yellow fruit. This species of Daphne occurs throughout the forests of Europe, and extends in Western Asia from the Caucasus to Altai. It is cultivated in Europe, and is occasionally found in our own gardens.

2. *Daphne gnidium.* Willd. *Sp. Plant.* ii. 420; *B. & T.* 227. In this species, called *garou* or *sain-bois* by the French, the leaves are linear-lanceolate, acute, entire, smooth, and irregularly but closely set upon the branches. The flowers are white, downy, odoriferous, and disposed in terminal panicled racemes. The fruit is globular, dry, at first green, but ultimately black. *D. gnidium* grows in dry uncultivated places in the south of Europe, and flowers in June. Its bark, which in France is used indiscriminately with that of the former species, is of a deep purplish-brown color, and hairy in the younger portions. It appears to be equally as active, medicinally, as the other official species.

Besides the species above described, *Daphne laureola*, or *spurge laurel*, is said to furnish a portion of the mezereum of commerce, and is recognized by the British Pharmacopœia; but its product is inferior in acrimony, and consequently in medicinal activity.

Mezereum bark. *r*, medullary rays; *s*, bast-bundles; *t*, parenchymatous tissue. (After Berg.)

The bark of the root was formerly directed; but the mezereum with which our markets are supplied is evidently the bark of the stem; and the Pharmacopœias at present very properly direct the bark, without designating the part from which it must be taken. British writers state that the bark of the root is the most active. The berries and leaves of the plant are also active; and the former have sometimes proved fatal to children who have eaten them. Pallas states that they are used as a purgative by the Russian peasants, and that thirty berries are required to act. French authors observe that fifteen are sufficient to kill a Frenchman. A tincture of them is used in Germany as a local application in *neuralgia*.

Properties. Mezereum, as it comes to us, chiefly from Germany, is in strips from two to four feet long and an inch or less in breadth, sometimes flat, sometimes partially rolled, and always folded in bundles or wrapped in the shape of balls. It is covered externally with a grayish or olive-, purplish-, or reddish-brown wrinkled epidermis, with transverse scars and minute black dots, very thin, and easily separable from the bark. Beneath the epidermis is a soft, greenish tissue. The inner bark is tough, pliable, fibrous, striated, and of a whitish color, with a silky surface. Its transverse section exhibits numerous groups of bast fibres in the secondary bast. When fresh it has a nauseous smell, but in the dry state is nearly inodorous. Its taste is at first sweetish, but afterwards highly acrid and even corrosive. It yields its virtues to water by decoction.

Vauquelin discovered a peculiar principle in the bark of *Daphne alpina*. This has subsequently been found in other species, and has received the name of *daphnin*. Gmelin and Bär found it in the bark of *D. mezereum*, associated with wax, an acrid resin, a yellow coloring matter, a reddish-brown extractive, an uncrystallizable and fermentable sugar, a gummy matter containing nitrogen, ligneous fibre, malic acid, and several malates. By J. B. Eng it has been discovered, together with a volatile oil, in the flowers of *D. mezereum*. (*Wittstein's Viertelj.*, viii. 23.) *Daphnin* is in prismatic crystals grouped together, colorless, transparent, brilliant, slightly soluble in cold water, very soluble in boiling water and alcohol, without odor, and of a bitter, somewhat austere taste. By Zwenger it is said to be insoluble in ether. The same chemist states that it has an acid reaction, and acts like the glucosides, being resolvable by sulphuric or hydrochloric acid into sugar, and a peculiar crystallizable principle called *daphnetin*, $C_9H_6O_4 + H_2O$. He gives for daphnin the formula $C_{15}H_{16}O_9 + 2H_2O$, the same as that of *æsculin*, of which it is, therefore, an isomer. (*Ann. Chem. und Pharm.*, cxv. 1.) It is obtained by treating the alcoholic extract of the bark with water, decanting the solution, precipitating with lead subacetate, filtering, decomposing the

excess of the subacetate by hydrogen sulphide, again filtering, evaporating to dryness, submitting the residue to the action of anhydrous alcohol, and evaporating the alcoholic solution to the point of crystallization. Though daphnin is probably not inert, it is not the principle upon which the virtues of mezereum chiefly depend. Vauquelin thinks that in the recent plant they reside in an essential oil, which by time and exposure is changed into a resin, without losing its activity. The acrid resin observed by Gmelin and Bär is probably the characteristic principle to which the bark owes its vesicating properties. It is obtained separate by boiling mezereum in alcohol, allowing the liquor to cool in order that it may deposit some wax which it has taken up, then distilling off the alcohol, and treating the residue with water, which leaves the resin. This is of a dark green, almost black color, hard and brittle, and of an exceedingly acrid and permanent taste. In the isolated state it is slightly soluble in water; and it is much more so when combined with the other principles of the bark. It appears, however, not to be a pure proximate principle, but rather a resinoid combination of an acrid fixed oil with another substance. The acrid principle of mezereum is partially given off by decoction with water, as proved by the irritating character of the vapor; but none of it appears to escape when the bark is boiled with alcohol. (Squire, *P. J. Tr.*, i.) Messrs. W. Will and O. Jung have investigated daphnetin, which was shown in 1879 by Stünkel to be *dioxycoumarin*, $C_6H_2(OH)_2<\begin{matrix}O & -CO\\ CH=&CH\end{matrix}$; they obtained but about one ounce of daphnetin from fifty pounds of extract of mezereum, and they proved that it has the same relation to pyrogallic acid that coumarin has to phenol, or umbelliferone to resorcin. (*A. J. P.*, 1885.) *Coccognin*, isolated in 1870 by Casselmann from the fruits of *D. mezereum*, appears to be closely allied to, if not identical with, daphnin. By the dry distillation of an alcoholic extract of mezereum bark, Zwenger obtained *umbelliferone*, $C_9H_6O_3$.

Medical Properties and Uses. The recent bark applied to the skin produces inflammation followed by vesication, and has been popularly used as an epispastic, from time immemorial, in some of the southern countries of Europe. The dried bark, though less active, is possessed of a similar property, and is occasionally employed in France by regular practitioners for the purpose of forming issues. A small square piece, moistened with vinegar, is applied to the skin, and renewed twice a day till a blister is formed, and occasionally afterwards to keep up the discharge. It is slow in its operation, generally requiring from twenty-four to forty-eight hours to vesicate. An irritant ointment* is prepared from mezereum, which is used for maintaining the discharge from blistered surfaces, and may be applied advantageously to obstinate, ill-conditioned, indolent *ulcers*. An alcoholic extract has also been employed to communicate irritant properties to issue-peas. Internally administered, mezereum is a stimulant capable of being directed to the skin or kidneys, and in large doses apt to excite purging, nausea, and vomiting. In overdoses it produces the fatal effects of the acrid poisons; and a case of apparently severe narcotic effects has been recorded. (*Am. Journ. of Med. Sci.*, xxi.) It had at one time much reputation as a remedy in the *secondary stages of syphilis*, and still enters as an ingredient into the official compound decoction of sarsaparilla. It has also been thought to act favorably as an alterative in *scrofulous affections*, *chronic rheumatism*, and *obstinate diseases of the skin*. For this purpose it is usually administered in decoction. The dose of the bark in substance is ten grains (0·60 Gm.); but it is seldom used.

MISTURÆ. Mixtures.

(MIS-TŪ'RÆ.)

Mixtures, *Fr.*; Mixturen, *G.*

This term should be restricted, in the language of pharmacy, to those preparations in which insoluble substances, whether solid or liquid, are suspended in watery fluids, by the intervention of gum arabic, sugar, yolk of egg, or other viscid matter. When the suspended substance is of an oleaginous nature, the mixture is properly called an *emulsion*, and the U. S.

* *Unguentum Mezerei.* U. S. 1880. *Mezereum Ointment.* (*Pommade épispastique au Garou, Pommade de Mézéréon*, Fr.; *Seidelbastsalbe*, G.) "Fluid Extract of Mezereum, *twenty-five parts* [or two fluidrachms]; Lard, *eighty parts* [or three hundred and sixty grains]; Yellow Wax, *twelve parts* [or fifty-four grains] [To make about one ounce av.]. Melt together the Lard and Wax with a moderate heat, add the Fluid Extract, and stir the mixture constantly until the alcohol has evaporated; then continue to stir until cool." *U. S.*

This ointment is equivalent to the *Pommade épispastique au Garou* of the French Codex, which is prepared from the bark of *Daphne gnidium*. It may also be made, as proposed by Guibourt, by mixing two drachms of the alcoholic extract of mezereum with nine ounces of lard and one ounce of wax. It is used as a stimulating application to *blistered surfaces* and to obstinate, ill-conditioned, and indolent *ulcers*.

Pharmacopœia of 1890 has recognized them by creating a special class for these. (See *Emulsa*, p. 509.) The object of these preparations is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines; and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of uniform and perfect mixtures. As a rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the inter-medium, before the aqueous vehicle is added. In Great Britain, and to some extent in this country, the term mixture is used indiscriminately for aqueous medicinal liquids having more than one ingredient, and for aqueous liquids which cannot be easily classified. Many of such liquids are perfectly transparent and should be in the class of Solutions.

MISTURA CREOSOTI. Br. Creosote Mixture.

(MIS-TŪ'RA CRĒ-O-SŌ'TĪ.)

Mixture de Créosote, *Fr.;* **Kreosot-Mixtur,** *G.*

"Creosote, 16 *minims* (Imperial measure) or 1 cubic centimetre; Spirit of Juniper, 16 *minims* (Imp. meas.) or 1 cubic centimetre; Syrup, 1 *fl. ounce* (Imp. meas.) or 30 cubic centimetres; Distilled Water, *a sufficient quantity*. Shake the Creosote with *fourteen fluid ounces* (Imp. meas.) or four hundred and twenty cubic centimetres of the Distilled Water; add the Syrup and the Spirit of Juniper, and sufficient Distilled Water to produce *sixteen fluid ounces* (Imp. meas.) or four hundred and eighty cubic centimetres of the Mixture." *Br.* The glacial acetic acid has been omitted from creosote mixture by the Br. Ph. 1898.

The dose of this mixture, which is too weak for practical use, is a fluidounce (30 C.c.), containing a minim of creosote.

MISTURA CRETÆ. U. S., Br. Chalk Mixture.

(MIS-TŪ'RA CRĒ'TÆ.)

Mixture avec la Craie, *Fr.;* **Kreidemixtur,** *G.*

"Compound Chalk Powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Cinnamon Water, *four hundred cubic centimeters* [or 13 fluidounces, 252 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Rub the Compound Chalk Powder, in a mortar, with the Cinnamon Water and about *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water gradually added, to a uniform mixture; transfer this to a graduated vessel, and rinse the mortar with enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the whole thoroughly. This preparation should be freshly made, when wanted." *U. S.*

"Prepared Chalk, ¼ *ounce* (Imperial) or 5 grammes; Tragacanth, in powder, 15 *grains* (Imp.) or 0·7 gramme; Refined Sugar, ½ *ounce* (Imp.) or 10 grammes; Cinnamon Water, *a sufficient quantity*. Triturate the Prepared Chalk with the Tragacanth and Refined Sugar, and gradually add sufficient Cinnamon Water to produce *eight fluid ounces* (Imp. meas.) or one hundred and sixty cubic centimetres of the Mixture." *Br.*

The direction that this mixture be prepared extemporaneously is a decided improvement. Unsuccessful attempts have been repeatedly made to devise a formula which would yield a permanent product, and much injury has been done through the dispensing of chalk mixture in an incipient fermentative condition. The trifling amount of glycerin present in the chalk mixture official in 1870 was totally inadequate to preserve it during the warm summer months, when it is in greatest vogue. Compound Chalk Powder is now official (see *Pulvis Cretæ Compositus*); it will keep indefinitely, and, besides being itself a valuable addition to the materia medica, is quickly made into chalk mixture by rubbing it with the water and cinnamon water, so that there can be no excuse for not dispensing a fresh mixture. This mixture is a convenient form for administering chalk, and is much employed in *looseness of the bowels* accompanied with acidity. Laudanum and kino or catechu are very often added to increase its astringency. The dose is a tablespoonful (15 C.c.) frequently repeated.

MISTURA FERRI COMPOSITA. U. S., Br. Compound Iron Mixture.

[Griffith's Mixture.]

(MIS-TŪ'RA FĔR'RĪ CŌM-PŎS'I-TA.)

Mixture de Griffith, *Fr.;* **Griffith's Eisenmixtur,** *G.*

"Ferrous Sulphate, in clear crystals, *six grammes* [or 93 grains]; Myrrh, in small pieces, *eighteen grammes* [or 278 grains]; Sugar, *eighteen grammes* [or 278 grains]; Potassium Car-

bonate, *eight grammes* [or 123 grains]; Spirit of Lavender, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Rose Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Rub the Myrrh, Sugar, and Potassium Carbonate, in a mortar, with *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of Rose Water, at first very gradually added, so that a uniform mixture may result. Transfer this to a graduated vessel, add the Spirit of Lavender, then the Ferrous Sulphate, previously dissolved in about *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of Rose Water, and, lastly, enough Rose Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the whole thoroughly. This preparation should be freshly made when wanted." *U. S.*

"Ferrous Sulphate, 25 *grains* (Imperial) or 2·5 grammes; Potassium Carbonate, 30 *grains* (Imp.) or 3 grammes; Myrrh, 60 *grains* (Imp.) or 6 grammes; Refined Sugar, 60 *grains* (Imp.) or 6 grammes; Spirit of Nutmeg, 50 *minims* (Imp. meas.) or 4·5 cubic centimetres; Rose Water, 10 *fl. ounces* (Imp. meas.) or 437·5 cubic centimetres or a sufficient quantity. Reduce the Myrrh to powder; add the Potassium Carbonate and Refined Sugar; triturate the mixture with a small quantity of the Rose Water so as to form a thin paste; gradually add more Rose Water and the Spirit of Nutmeg; continue the trituration and further addition of Rose Water until *seven fluid ounces* (Imp. meas.) or three hundred and six and a quarter cubic centimetres of liquid result; dissolve the Ferrous Sulphate in *three fluid ounces* (Imp. meas.) or one hundred and thirty-one and a quarter cubic centimetres of the Rose Water; mix the liquids." *Br.*

This is very nearly the same with the celebrated tonic or anti-hectic myrrh mixture of Dr. Griffith. The ferrous sulphate is decomposed by the potassium carbonate, with the production of potassium sulphate and ferrous carbonate; while the excess of the alkaline carbonate forms a saponaceous compound with the myrrh. The mixture is at first of a greenish color, which it loses upon exposure to the air, in consequence of the conversion of the ferrous carbonate into the ferric compound. Mr. C. A. Staples remedies this tendency by making a concentrated myrrh emulsion of such strength that one fluidrachm of it contains the amount of myrrh and potassium carbonate found in a fluidounce of the official mixture, and also a concentrated syrup of ferrous sulphate, fifteen minims of which equal one fluidounce of Mistura Ferri Composita. When the latter is called for, the emulsion, properly diluted, is put in a bottle and the requisite quantity of the iron syrup added. (*A. J. P.*, Nov. 1871.) The official solution may, however, be kept for some time without change, if the vessel in which it is contained be well closed; but the best plan is to prepare it extemporaneously. The sugar contained in it contributes somewhat to retard the further oxidation of the ferrous salt, and if considerably increased in amount would act still more efficiently. The finest pieces of myrrh in lump should be selected, and rubbed down for the occasion with a little of the rose water, as the powdered myrrh of commerce is often impure, and otherwise does not make a good mixture, owing mainly to its loss of volatile oil.

This mixture is a good tonic in *debility of the digestive organs*, especially when attended with derangement of the menstrual function. Hence it is used with advantage in *chlorosis* and *hysterical affections*. It has been also much employed in the hectic fever of *phthisis* and *chronic catarrh*. It is contra-indicated by the existence of inflammation of the gastric mucous membrane. The dose is from one to two fluidounces (30–60 C.c.) two or three times a day.

MISTURA GLYCYRRHIZÆ COMPOSITA. U.S. Compound Mixture of Glycyrrhiza. [Brown Mixture.]

(MIS-TŪ'RA GLĬÇ-ĬR-RHĪ'ZÆ CŌM-PŎŞ'Ī-TA.)

Mixture de Réglisse, *Fr.*; Lakrizen-Mixtur, *G.*

"Pure Extract of Glycyrrhiza, *thirty grammes* [or 1 ounce av., 25 grains]; Syrup, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Mucilage of Acacia, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Camphorated Tincture of Opium, *one hundred and twenty cubic centimeters* [or 4 fluidounces, 28 minims]; Wine of Antimony, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Spirit of Nitrous Ether, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Rub the Pure Extract of Glycyrrhiza, in a mortar, with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water, until it is dissolved. Transfer the solution to a graduated vessel containing the other ingredients, and rinse the mortar with enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Mix the whole thoroughly." *U. S.*

This is an exceedingly popular cough mixture, which was made official in the U. S. Pharmacopœia of 1850. The Sugar in the U. S. 1880 formula has been replaced by Syrup, and the mixture made sweeter, and the Acacia has been replaced by Mucilage of Acacia. The latter change is of doubtful utility; indeed, the stability of the mixture would be improved if acacia were left out entirely: the "body" which seems to be needed could be much better supplied by the use of glycerin. The substitution in the official process of 1880 of pure Extract of Liquorice for the former impure powdered extract was undoubtedly an improvement; although by the change the mixture has lost somewhat its original appearance, and a large proportion of the precipitate which gave it a distinctive character. The spirit of nitrous ether is probably useful by somewhat retarding decomposition. W. L. Stephen (*A. J. P.*, 1892, 563) prefers a mixture without sediment, which he makes by rubbing into a paste half an ounce each of acacia, glycyrrhiza, and sugar with six fluidounces of water, heating until fluid, then adding half a fluidounce of spirit of nitrous ether, one fluidounce of wine of antimony, two fluidounces of camphorated tincture of opium, and sufficient water to make a pint. The dose is from one to two tablespoonfuls (15–30 C.c.) for an adult; a teaspoonful (3·75 C.c.) for a child two years old. It should be well shaken when administered.

MISTURA GUAIACI. Br. Guaiacum Mixture.

(MĮS-TŪ'RĄ GUĀ'IĄ-CĪ—gwā'yą-sī.)

Emulsio Resinæ Guaiaci; Emulsion de Résine de Gaïac, Lait de Gaïac, *Fr.*; Guajak-Emulsion, *G.*

"Guaiacum Resin, ½ *ounce* (Imperial) or 10 grammes; Refined Sugar, ½ *ounce* (Imp.) or 10 grammes; Tragacanth, in powder, 35 *grains* (Imp.) or 1·6 grammes; Cinnamon Water, 1 *pint* (Imp. meas.) or 400 cubic centimetres. Triturate the Guaiacum Resin with the Refined Sugar and the Tragacanth; add gradually the Cinnamon Water." *Br.*

For the changes of color which the Guaiac in this mixture undergoes, and which it produces in other substances, see *Guaiaci Resina*, p. 674. Tragacanth was substituted for acacia in the Br. Ph. 1898 process. From one to four tablespoonfuls (15–60 C.c.) may be given for a dose, repeated two or three times a day, or more frequently.

MISTURA OLEI RICINI. Br. Castor Oil Mixture.

(MĮS-TŪ'RĄ Ō'LĘ-Ī RIÇ'Į-NĪ.)

"Castor Oil, 3 *fl. ounces* (Imperial measure) or 75 cubic centimetres; Mucilage of Gum Acacia, 1½ *fl. ounces* (Imp. meas.) or 37·5 cubic centimetres; Orange-flower Water of commerce, undiluted, 1 *fl. ounce* (Imp. meas.) or 25 cubic centimetres; Cinnamon Water, 2½ *fl. ounces* (Imp. meas.) or 62·5 cubic centimetres. Mix the undiluted Orange-flower Water and the Cinnamon Water; place the mucilage of Gum Acacia in a mortar and to it add, alternately, in portions, the Castor Oil and the mixed Waters, with constant trituration." *Br.*

This emulsion of the British Pharmacopœia might be termed a "perfumed dose of castor oil." The dose is from one-half to two fluidounces (15–60 C.c.).

MISTURA RHEI ET SODÆ. U. S. Mixture of Rhubarb and Soda.

(MĮS-TŪ'RĄ RHĒ'Ī ĔT SŌ'DÆ.)

"Sodium Bicarbonate, *thirty-five grammes* [or 1 ounce av., 103 grains]; Fluid Extract of Rhubarb, *fifteen cubic centimeters* [or 243 minims]; Fluid Extract of Ipecac, *three cubic centimeters* [or 49 minims]; Glycerin, *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims]; Spirit of Peppermint, *thirty-five cubic centimeters* [or 1 fluidounce, 88 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Dissolve the Sodium Bicarbonate in about *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Then add the Fluid Extracts, the Glycerin, and the Spirit of Peppermint, and, lastly, enough Water to make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]." *U. S.*

This is a preparation which closely resembles one which has been used in Brooklyn, N.Y., the formula of which was published by Dr. E. R. Squibb. The ingredients in the original preparation were fluid extract of ipecac 51 minims, fluid extract of rhubarb 256 minims, sodium bicarbonate 512 grains, glycerin 12 fluidounces, peppermint water 2 pints. The formula in the U. S. P. 1880 did not contain fluid extract of ipecac. The official mixture may be given to children as a stomachic and carminative in the dose of from one-half to one teaspoonful (1·9–3·75 C.c.) two or three times a day.

MISTURA SENNÆ COMPOSITA. Br. Compound Mixture of Senna.

(MĮS-TŪ'RĄ SĔN'NÆ CŌM-PŎS'Į-TĄ.)

Black Draught; Tisane de Séné composée, *Fr.*; Senna-Aufguss, *G.*

"Magnesium Sulphate, 5 *ounces* (Imperial) or 250 grammes; Liquid Extract of Liquorice, 1 *fl. ounce* (Imp. meas.) or 50 cubic centimetres; Compound Tincture of Cardamoms, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Aromatic Spirit of Ammonia, 1 *fl. ounce* (Imp. meas.) or 50 cubic centimetres; Infusion of Senna, *a sufficient quantity*. Dissolve the Magnesium Sulphate in *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Infusion of Senna; add the mixed Liquid Extract of Liquorice, Compound Tincture of Cardamoms, and Aromatic Spirit of Ammonia; and enough Infusion of Senna to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Compound Mixture." *Br.*

This is a new form of Compound Infusion of Senna, called commonly *black draught*. We prefer the form given under *Infusum Sennæ Compositum*, as being more easily prepared and quite as efficient. Dose (Br. Pharm.), from one to one and a half fluidounces (30–45 C.c.).

MISTURA SPIRITUS VINI GALLICI. Br. Mixture of Brandy.

(MĮS-TŪ'RĄ SPĬR'Į-TŬS VĪ'NĪ GĂL'LĮ-CĪ.)

Mixture de Cognac, *Fr.*; Branntwein-Mixtur, *G.*

"Brandy, 4 *fl. ounces* (Imperial measure) or 113 cubic centimetres; Cinnamon Water, 4 *fl. ounces* (Imp. meas.) or 113 cubic centimetres; Refined Sugar, ½ *ounce* (Imp.) or 14 grammes; Two yolks of eggs. Rub the yolks of eggs and Refined Sugar together; add the Cinnamon Water and Brandy; mix." *Br.*

This nutritious and stimulant draught is scarcely entitled to a place in the Pharmacopœia. It serves the purpose, however, of enabling the practitioner to prescribe the stimulant under an official designation. Dose, from one to two fluidounces (30–60 C.c.).

MORPHINA. U. S. Morphine.

$C_{17}H_{19}NO_3 + H_2O$; 302·34. (MÖR-PHĪ'NĄ.) $C_{17}H_{19}NO_3.H_2O$; 303.

"An alkaloid obtained from Opium." *U. S.*

Morphia, *U. S.* 1870; Morphinum, *P. G.*; Morphium, Morphina; Morphine, *Fr.*; Morphin, *G.*

The U. S. Pharmacopœia no longer contains a process for the extraction of morphine: that of 1870, which has been known as Staples's process, is given in the foot-note.*

Various processes for preparing morphine have been employed. In most of them the morphine is extracted from opium by maceration with water, either pure or acidulated, is then precipitated by ammonia, and is afterwards purified by the agency of alcohol, or by repeated solution in a dilute acid and precipitation. Sertürner, the discoverer of morphine, made an infusion of opium in distilled water, precipitated the morphine by ammonia in excess, dissolved the precipitate in dilute sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol, and crystallization. In evaporating aqueous solutions containing morphine a temperature of 40° C. (104° F.) should not be exceeded.

Properties. Morphine crystallizes from alcohol in the form of small, colorless, shining crystals. It is officially described as follows: "Colorless or white, shining, prismatic crystals, or fine needles, or a crystalline powder, odorless, and having a bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 4350 parts of water, and in 300 parts of alcohol; in 455 parts of boiling water, and in 36 parts of boiling alcohol; also soluble in 4000 parts of ether. When heated to about 75° C. (167° F.), Morphine begins to lose its water of crystallization. Heated for some time at 100° C. (212° F.), it becomes anhydrous. At 254° C. (489·2° F.) it melts, forming a black liquid. Upon ignition, it is consumed without leaving a residue. Morphine has an alkaline reaction upon litmus paper. When crystals of Morphine are sprinkled upon nitric acid (specific gravity 1·250 to 1·300), they will assume an orange-red color, and

* "Take of Opium, sliced, *twelve troyounces*; Water of Ammonia *six fluidounces*; Animal Charcoal, in fine powder, Alcohol, Distilled Water, each, *a sufficient quantity*. Macerate the Opium with four pints of Distilled Water for twenty-four hours, and, having worked it with the hand, again macerate for twenty-four hours, and strain. In like manner, macerate the residue twice successively with the same quantity of Distilled Water, and strain. Mix the infusions, evaporate to six pints, and filter; then add five pints of Alcohol, and afterwards three fluidounces of the Water of Ammonia, previously mixed with half a pint of Alcohol. After twenty-four hours, pour in the remainder of the Water of Ammonia, mixed, as before, with half a pint of Alcohol; and set the liquid aside for twenty-four hours that crystals may form. To purify these, boil them with two pints of Alcohol until they are dissolved, filter the solution, while hot, through Animal Charcoal, and set it aside to crystallize." *U. S.* For other processes, see *U. S. D.*, 17th ed., 876.

then produce a reddish solution gradually changing to yellow. On shaking a small portion of Morphine, in a test-tube, with 10 C.c. of chlorine water, the latter will acquire a yellowish color. On now carefully pouring a small amount of ammonia water on the surface of the liquid, a brown or reddish-brown zone will form at the line of contact of the two liquids. If to a neutral 1-per-cent. solution of Morphine, made by the careful addition of dilute sulphuric acid, a few drops of ferric chloride test-solution be added, a blue color will be produced which is destroyed by acids, alcohol, or heating. On treating Morphine with cold, concentrated sulphuric acid free from nitric acid, the liquid should not at once acquire more than a faintly yellowish tinge (absence of more than traces of *narcotine*, *papaverine*, etc.); and the subsequent addition of a small crystal of potassium permanganate should produce only a greenish, but no violet or purple, color (difference from *strychnine*). On precipitating a solution of any of the salts of Morphine by ammonia water, dissolving the washed precipitate in sodium hydrate test-solution, shaking the solution with an equal volume of ether, and evaporating the ethereal solution, no appreciable residue should remain (absence of *narcotine*, *codeine*, etc.). On adding 4 C.c. of potassium or sodium hydrate test-solution to 0·2 Gm. of Morphine, a clear, colorless solution, free from any undissolved residue, should result (absence of, and difference from, *various other alkaloids*)." *U. S.*

Von Gerichten and Schrötter (*Ber. der Chem. Ges.*, 1882, pp. 1484 and 2179) showed that morphine and codeine were derivatives of phenanthrene, as when distilled with zinc dust they yielded phenanthrene, pyridine, and quinoline. Knorr (*Ber. der Chem. Ges.*, 22, p. 2081) has made it very probable that morphine contains, combined with the phenanthrene nucleus, the *morpholine* group. Morpholine, $NH<\begin{matrix}CH_2\cdot CH_2\\CH_2\cdot CH_2\end{matrix}>O$, is formed when dioxyethylamine is heated to 160° C. with hydrochloric acid, or is boiled with alkali. As seen from the formula, it bears a structural relation to both pyrrol and pyridine. For later views on the structure of the morphine molecule by Knorr and Vis, see *Proc. A. P. A.*, 1894, 1122.

Heated in the open air, morphine burns with a bright flame, and at a red heat is wholly dissipated. In the products resulting from the combustion of opium or morphine this alkaloid may be detected, proving that it is partly volatilized when burned. (Descharmes, *Arch. Gén.*, Fév. 1855, 240.) Morphine in solution is to a considerable extent absorbed by animal charcoal, which, though it will part with most of the alkaloid to alcohol, cannot be wholly deprived of it by repeated washings with that liquid, either cold or hot. (Lefort, *Journ. de Pharm.*, Août, 1861, 98.) Its solution restores the blue color of litmus paper reddened by acids, and turns the yellow of turmeric to brown. Hager (*Ph. Zeit.*, 93, 250, also *Proc. A. P. A.*, 1893, 680) states that on heating solutions containing morphine, oxygen is absorbed gradually and oxymorphine is formed; at a boiling temperature this change proceeds rapidly. The oxymorphine is much less active as a narcotic than is morphine. With the acids morphine forms salts, which are generally soluble, and are decomposed by the alkalies. It is dissolved also by the fixed and volatile oils. The solutions of potassa and soda also dissolve morphine, which is precipitated slowly from them on exposure to the air, in consequence of the absorption of carbonic acid. Solution of ammonia has to a certain extent the same solvent power; and hence the necessity, in precipitating morphine by this alkali, not to employ it in great excess. Solution of iodine with potassium iodide precipitates the salts of morphine in aqueous solution. With chlorine water morphine and its salts assume an orange color, and the same effect is produced on them by solution of chlorinated soda. (Fairthorne, *A. J. P.*, xxviii. 9.) By the contact of nitric acid they assume a blood-red color, which ultimately changes to yellow; and this is one of the tests of morphine; but, as the same change of color is produced with brucine and impure strychnine, it cannot be relied on in the absence of other evidence. Nitric acid also produces a red color with oil of cloves, but in this case the red does not change to yellow. When added to a solution of iodic acid, or an acidulous iodate, morphine and its salts redden the liquid and set iodine free. (*Sérullas.*) This is a very delicate test, but is not conclusive, as various other organic substances act in a similar manner. M. J. Lefort, however, has found that the color produced by these substances is removed by ammonia, while the redness produced with morphine is greatly intensified by addition of that alkali. This test, thus modified by the addition of ammonia, is so delicate that, according to M. Lefort, it will detect one part of morphine in 10,000 parts of a liquid holding it in solution. (*Journ. de Pharm.*, Août, 1861, 113.)* Husemann's test consists in leaving

* *Stas's Method of extracting the Alkaloids from Mixtures.* To separate the alkaloid from foreign matters, the mixture is treated alternately with water and alcohol in different degrees of concentration; the liquors thus obtained are filtered; tartaric or oxalic acid, but preferably the former, is added in excess; the mixture is heated to 71·1° or

morphine or its salt in contact with concentrated sulphuric acid for 12 or 15 hours, or in heating for half an hour with the acid to 100° C. (212° F.), and then adding either a little nitric acid, a nitrate or chlorate or chlorine water, or chlorinated soda, when a beautiful bluish or reddish-violet color, passing into deep blood-red and gradually paling, is developed. The presence of small quantities of coloring matter does not prevent this reaction, if chlorinated reagents are selected. A. Husemann asserts that this test will recognize the hundredth part of a milligramme of the alkaloid. (*A. J. P.*, xlvii. 210.) According to R. Schneider, a very delicate test is afforded by putting a drop of the suspected liquid on a plate, saturating with sugar, and putting alongside of it a drop of sulphuric acid; if morphine be present, a very intense purple will be developed at the point of contact, passing after half an hour into violet, then bluish green, and finally dirty yellow. (*Journ. de Pharm.*, 4e sér., xviii. 221.) According to H. Weppen, the delicacy of this test is much increased by the addition of a minute quantity of bromine water to the solution. Codeine and aconitine are stated, however, to give the same reaction. (*Ibid.*, 4e sér., xix. 246.)

Fröhde's reagent (a fresh solution of ·005 Gm. sodium molybdate in 1 C.c. of pure concentrated sulphuric acid) strikes with morphine and its salts a beautiful blue-violet color, passing into blue, then green, finally back to bluish violet. This reaction is stated to be delicate but not characteristic. Prof. A. B. Prescott gives a thorough résumé of the views of investigators on this test in *A. J. P.*, 1876, 59. Bruylants combines Froehde's test with that of Husemann. A trace of Froehde's reagent added to a solution of morphine in sulphuric acid produces the well-known lilac tint; if the sulphuric acid solution be warmed and treated in the same way, a green tint will be noted. On dropping a particle of potassium nitrate into this green liquid, the color changes to red and finally yellowish. The other opium alkaloids give different tints. (*Proc. A. P. A.*, 1895, 1016.) In the presence of sulphuric acid morphine exhibits surprising powers as a reducing agent. Among the most notable instances of deoxidation may be mentioned those of silver oxide, hydrated bismuth oxide, the acids of tin, tungsten, vanadium, titanium, and molybdenum. A solution of titanic acid in concentrated sulphuric acid is one of the most delicate reagents for morphine. An intense brown-red to violet color is produced if titanic acid is added to concentrated sulphuric acid containing a trace of morphine in solution. (Flückiger, *N. R.*, Feb. 1880. See, also, *N. R.*, 1881, p. 237.) M. H. Kalbrunner states that the most sensitive test is made with a solution (No. 1) of crystallized ferric chloride (thirty grains to four fluidrachms of distilled water) and a fresh solution (No. 2) of potassium ferricyanide (two grains in four drachms). To the suspected liquor five or six drops of No. 1 are added, and afterwards three or four drops of No. 2. If morphine be present, a color varying from deep blue to pale blue and bluish green, according to the proportion of the alkaloid, is developed. Neither gum, sugar, alcohol, glycerin, atropine, quinine, nor strychnine interferes with this test. An excess of alkali does so by decomposing the ferric chloride. This test depends upon the fact that the potassium ferricyanide solution is reduced by morphine to the ferrocyanide. It is affirmed that even $\frac{1}{60000}$ of one per cent. of morphine can be detected. (*Ibid.*; see also *Proc. A. P. A.*, 1897, 701.) G. Vulpius (*Arch. d. Pharm.*, 1887, 25) states that if about 0·00025 Gm. of a morphine salt be dissolved in a porcelain dish in about six drops of concentrated sulphuric acid, a few centigrammes of sodium phosphate added, and the mixture carefully heated, white fumes will be evolved and a violet color appear. On adding water drop by drop, a brilliant red appears, which, on further addition, changes to a dirty green. If the solution be then shaken with the same volume of chloroform, the latter will be colored blue. Isobutylic alcohol has been used by Nagelvoort for the detection of morphine and codeine. (See *Proc. A. P. A.*, 1894, 273.)

M. Siebold heats gently the suspected substance with some drops of concentrated sulphuric acid and a small quantity of chemically pure potassium perchlorate: a deep brown color will be produced if morphine be present. (*P. J. Tr.*, Oct. 1873.) According to H. S. Wellcome, one part of morphine in ten thousand parts of water can be recognized by chlorine water, if care be exercised not to decolorize by an excess of the reagent; the color varies from light orange-

76·6° C. (160° or 170° F.); the whole is placed upon a filter; the deposited matter is washed with concentrated alcohol; the alcoholic solution is evaporated at a temperature not exceeding 35° C. (95° F.); the residue is introduced into a small bottle; a solution of caustic potassa or soda is added, little by little, and afterwards four or five times the measure of ether; the mixture is shaken and then allowed to stand; and, finally, the ether is decanted, and yields the alkaloid by spontaneous evaporation. Stas included morphine among the alkaloids thus separable, though known to be nearly insoluble in ether; but Lefort has shown that the process is not applicable to that alkaloid. (*Journ. de Pharm.*, Août, 1861, p. 99.) M. Alfred Valser, however, has ascertained that, if acetic ether be substituted for ether, the process is equally applicable to morphine. (See *A. J. P.*, Sept. 1864, p. 439.)

red to deep red according to the proportion of morphine present. Brucine is the only other alkaloid giving the same reaction; but, while the color produced by morphine is discharged by excess of chlorine, that caused by brucine is not affected. (*A. J. P.*, 1874, p. 305.) To discover morphine in the presence of quinine, see *ibid.*, p. 361. Morphine and its salts assume a fine blue color with ferric chloride; at least this is true of the alkaloid, its sulphate, acetate, and oxalate; and the same effect will be produced by the other salts, if previously decomposed by an alkali; but that this test should be satisfactory it is necessary to operate on morphine either in powder or in concentrated solution. (*Lefort.*) Water, acids, and alkalies, added in large quantity to the blue compound formed, destroy its color. According to Pelletier, moreover, there occasionally exists in opium a principle, called by him *pseudomorphine*, which becomes red under the action of nitric acid and changes ferric salts blue, and yet is destitute of poisonous properties: so that the occurrence of these phenomena in any medico-legal case cannot be considered certain evidence of the presence of morphine. (See *A. J. P.*, viii. 77.) Auric chloride precipitates morphine first yellow, then bluish, and lastly violet. (*Larocque and Thibierge.*) Copper peroxide and silver oxide are precipitated by morphine from their ammoniacal solutions. (*Chem. Gaz.*, No. 367, p. 54.) A solution of morphine acetate or sulphate containing only one part of the salt in 100 precipitates silver from a solution of the nitrate of that metal. (*Horsley.*) Morphine is precipitated from its solutions by potassa or soda, and redissolved by an excess of the alkali. Infusion of galls and other vegetable substances containing tannic acid precipitate morphine in the state of a tannate, which is soluble in acetic acid; but, according to Dublanc, the alkaloid is not precipitated by pure gallic acid. If ammonia be added to a mixture of the solutions of chlorine and morphine, there will be produced a dark brown color, which will be destroyed by a further addition of chlorine. For methods of separating narcotine, see *U. S. D.*, 17th ed., 879.

The proportion of pure morphine which Turkey opium is capable of affording varies from 9 per cent., or less, to 20 per cent., according to the quality of the drug; but much less than the least quantity mentioned is often obtained, in consequence of the incomplete exhaustion of the opium, the loss in the process for preparing it, the destructive action of heat, or inferiority in the quality of the drug. (See *Opium.*) Formaldehyde reacts with both morphine and codeine to form medically active condensation products by the union of two molecules of the base with one molecule of the formaldehyde, with elimination of water. That formed from morphine is an amorphous base, difficultly soluble in water but easily soluble in alkaline solution and in alcohol. It melts at 270° C., and forms a hydrochlorate soluble in water. (*Proc. A. P. A.*, 1897, 702.)

Medical Properties. There can be no doubt that morphine is the chief narcotic principle of opium, from which, however, it differs somewhat in its mode of action. The difference probably arises in part from the peculiar state of combination in which morphine exists in opium, but chiefly from other narcotic principles being associated with it. In consequence of its insolubility in water, morphine in its pure state is less convenient than its salts, which are therefore always preferred. The acetate, sulphate, and hydrochlorate have been employed. Between these there is a great similarity of action, and what may be said of one, in regard to its therapeutic effects, will equally apply to the others. They have the anodyne, soporific, and diaphoretic properties of opium, but are less stimulant, and less disposed to constipate the bowels. The morphine salts are perhaps less apt to cause disagreeable after-effects than is opium, but the deodorized tincture is certainly preferable to them for many purposes. A great advantage which they possess is the convenience of their external application to blistered surfaces, and the certainty of their effects when thus applied. In cases which do not admit of the internal use of opium or its preparations, morphine acetate or sulphate, sprinkled, in triple the ordinary dose, upon a blistered surface denuded of the cuticle, will be found to exercise upon the system all the influence it is capable of exerting when taken into the stomach. Applied in this manner, these salts are peculiarly useful in relieving violent neuralgic pains, and in controlling obstinate sickness of the stomach. When intended to act on the system through the medium of the skin, they should be applied preferably to the epigastrium; when to act locally, as near the affected part as possible. Solutions of the salts of morphine also sometimes operate very favorably, both generally and locally, when injected, by means of a hypodermic syringe, into the areolar tissue beneath the skin.* Oleic acid has also been proposed as a vehicle for morphine externally

* *Morphine Lactate* ($C_{17}H_{19}NO_3,C_3H_6O_3$). This salt crystallizes in four-sided prisms, one part being soluble in eight parts of water and ninety-three parts of alcohol. (*P. J. Tr.*, 1886, 958.)

Morphine Hydrocyanate. Prof. J. M. Maisch has noticed that when a soluble salt of morphine is added to a

used, as it dissolves both the alkaloid and its salts perfectly in considerable proportion. A liniment has been proposed, consisting of 300 parts of oleic acid and 1 part of morphine, scented with a little oil of bergamot. (*Ibid.*, xxvi. 302.)

The toxicology of morphine is identical with that of opium.

As the proportion of acid necessary to neutralize morphine is very small, the dose of the alkaloid is the same as that of its salts. One-fourth of a grain (0·016 Gm.) may be considered about equivalent to a grain of opium of the medium strength.

MORPHINÆ ACETAS. U. S., Br. Morphine Acetate.

(MÖR-PHĪ'NÆ Ą-CĒ'TĂS.)

$C_{17}H_{19}NO_3C_2H_4O_2 + 3H_2O$; 398·12. $C_{17}H_{19}NO_3.HC_2H_3O_2.3H_2O$; 399.

"Morphine Acetate should be kept in dark amber-colored, well-stoppered vials." *U. S.*

"The carefully dried salt, $C_{17}H_{19}NO_3,C_2H_4O_2,3H_2O$, obtained by neutralizing morphine with acetic acid." *Br.*

Morphiæ Acetas, *Br.* 1867, *U. S.* 1870; Acetate of Morphia; Morphinum Aceticum, *P. G.;* Acetas Morphicus; Acétate de Morphine, *Fr.;* Essigsaures Morphin, *G.*

A process for this salt is no longer official: that of the U. S. P. 1870 is appended.*

In the U. S. process of 1870, morphine is saturated with acetic acid, which is employed in preference to vinegar for saturating the alkaloid, because it can leave no impurity in the resulting salt. The solution of the morphine in the water is an indication that it is saturated. A small excess of acid is attended with no inconvenience, as it is subsequently driven off by the heat. Care is required not to employ too much heat in the evaporation, as the acetate is easily decomposed, a portion of the acetic acid escaping, and leaving an equivalent portion of uncombined morphine. With attention to arrest the evaporation at a certain point, the acetate may be obtained in the state of crystals; but the crystallization is attended with some difficulty, and evaporation to dryness is almost universally preferred. Some recommend to dissolve the morphine in boiling alcohol, instead of suspending it in water, previously to the addition of the acetic acid. Less heat is thus required in the evaporation, and impurities in the morphine may often be detected, as they are apt to be insoluble in alcohol. To ascertain, in this case, whether the morphine is saturated, it is necessary to employ litmus paper, the blue color of which should not be restored if previously reddened by an acid. If the morphine used in preparing the acetate contain narcotine, it will be best to employ as the solvent distilled vinegar, or diluted acetic acid of the same strength, and to favor its solvent power by heat. Under these circumstances it dissolves only the morphine, leaving the narcotine nearly or quite untouched. (Hodgson, *Journ. Phila. Coll. Pharm.*, v.) The British process (1885) differed from that of the U. S. Pharmacopœia of 1870 only in obtaining uncombined morphine, as the first step, by precipitating it from a solution of the hydrochlorate, morphine itself not being official.

It is officially described as "a white or faintly yellowish-white, crystalline or amorphous powder, having a faint, acetous odor, and a bitter taste. It slowly loses acetic acid when exposed to the air. Soluble, at 15° C. (59° F.), when freshly prepared, in 2·5 parts of water, and in 47·6 parts of alcohol; in 1·5 parts of boiling water, and in 14 parts of boiling alcohol; also soluble in about 1700 parts of ether, 2100 parts of cold chloroform, and 60 parts of boiling chloroform. On protracted exposure to the air the salt gradually loses some acetic acid, and becomes less soluble. When heated, the salt loses water as well as acetic acid. Upon ignition, it is consumed, leaving no residue. The salt is neutral or faintly alkaline to litmus paper. The addition of potassium or sodium hydrate test-solution to an aqueous solution of the salt causes a white precipitate, which is soluble in an excess of the alkali, and which conforms to the reactions and tests of Morphine (see *Morphina*). On adding sulphuric acid to

solution of soluble cyanide, crystals of morphine hydrocyanate form. This salt, although sparingly soluble in water, is freely dissolved by that liquid when acidulated. It is evident that potassium cyanide and morphine should not be prescribed together in solution, except in connection with free acid.

Morphine Hydrobromate, or *Morphine Bromide* ($C_{17}H_{19}NO_3HBr + 2H_2O$), is made by double decomposition between morphine sulphate and barium bromide. (See *A. J. P.*, xliv. 447.)

Morphine Phthalate is made by adding pure morphine to a hot solution of *absolutely pure* phthalic acid as long as it is dissolved, filtering, and evaporating. One part of the salt is soluble in five parts of water. The solutions are perfectly neutral, and have been especially recommended by E. Bombelon for hypodermic use. (*Pharm. Ztg.*, 1887, 488.)

* *Morphiæ Acetas*, U. S. 1870. "Take of Morphia, in fine powder, *a troyounce;* Distilled Water *half a pint;* Acetic Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water; then carefully drop Acetic Acid into the mixture, stirring it constantly until the Morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath, to the consistence of syrup, and set aside until it concretes. Lastly, dry the salt with a gentle heat, and rub it into powder."

the salt, vapors of acetic acid are evolved." *U. S.* "A white crystalline or amorphous powder, almost entirely soluble in 2½ parts of *water* and in about 100 parts of *alcohol* (90 per cent.). It loses acetic acid when exposed to the air. It affords the reactions for morphine mentioned under 'Morphinæ Hydrochloridum,' and the reactions characteristic of acetates. 2 grammes of the salt form with 6 cubic centimetres of warm *morphinated water* a slightly turbid solution, which is rendered clear by the addition of 0·1 cubic centimetre of *acetic acid;* and this solution, when mixed with *solution of ammonia* in slight excess, yields a precipitate which, after washing and drying as described under 'Morphinæ Hydrochloridum,' weighs 1·42 grammes. If the salt yield a larger proportion of morphine than this, it should be recrystallized from hot water acidulated with *acetic acid.* Heated to redness with free access of air, it leaves no residue (absence of mineral impurities)." *Br.* Morphine acetate crystallizes in slender needles united in fasciculi. As ordinarily obtained by evaporation to dryness, it is not entirely soluble in water, a portion of it being uncombined morphine. To render it soluble, all that is necessary is to add a little acetic acid.

This and the other official salts of morphine are of identical medical value. They are almost invariably preferred to the alkaloid itself, and are given by the mouth, in pill or solution, in doses of from one-eighth to one-half grain (0·008–0·03 Gm.). They are employed externally, sprinkled on blistered surfaces, and are very frequently exhibited by subcutaneous injection; but great caution must be observed that they be not thrown into a vein. We have seen one-sixth of a grain thus given produce almost instantaneous insensibility, with dropping of jaw, and other evidence of immediate death, from which the patient was saved with difficulty. When given hypodermically fifteen minutes before the anæsthetic, the morphine salt was found by Claude Bernard to prolong and intensify the anæsthesia in animals, and many surgeons have employed it in man in this way, with satisfactory results. The solutions for hypodermic use should be freshly prepared, as morphine salts, especially the acetate, are very prone to undergo decomposition, through the growth of a fungus.

MORPHINÆ HYDROCHLORAS. U. S. (Br.) Morphine Hydrochlorate.

(MÖR-PHĪ'NÆ HŸ-DRO-ȻHLŌ'RĂS.)

$C_{17}H_{19}NO_3.HCl + 3H_2O$; 374·63. $C_{17}H_{19}NO_3.HCl.3H_2O$; 375.

"The hydrochloride, $C_{17}H_{19}NO_3,HCl,3H_2O$, of an alkaloid obtained from opium." *Br.*

Morphinæ Hydrochloridum, *Br.*, Morphine Hydrochloride; Morphiæ Murias, *Br.* 1867, *U. S.* 1870; Morphinum Hydrochloricum, *P. G.;* Murias (Hydrochloras) Morphicus; Muriate of Morphia; Chlorhydrate de Morphine, *Fr.;* Salzsaures Morphin, *G.*

A process for this salt is no longer official: that of the U. S. P. 1870 is appended.* The British process (1885) will be found in *U. S. D.*, 17th ed., 882.

Morphine hydrochlorate crystallizes in "white, feathery needles of a silky lustre, or minute, colorless, needle-shaped crystals, odorless, and having a bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 24 parts of water, and in 62 parts of alcohol;† in 0·5 part of boiling water, and in 31 parts of boiling alcohol. Very slightly soluble in ether or chloroform. When heated at 100° C. (212° F.), the salt loses its water of crystallization (14·38 per cent.); at 300° C. (572° F.) it coheres slightly, but does not completely melt; and upon ignition it is consumed, leaving no residue. The salt is neutral to litmus paper. The addition of potassium or sodium hydrate test-solution to an aqueous solution of the salt causes a white precipitate, soluble in an excess of the alkali, and conforming to the reactions and tests of Morphine (see *Morphina*). The aqueous solution of the salt yields, with silver nitrate test-solution, a white precipitate insoluble in nitric acid." *U. S.* "Acicular prisms of a silky lustre, or a white powder consisting of minute cubical crystals, unchanged by exposure to the air. Soluble in 24 parts of cold *water*, 1 part of boiling *water*, and in 50 parts of *alcohol.* It should be without action on *litmus.* *Solution of ammonia* causes a white precipitate in the aqueous solution, with difficulty soluble in excess; *solution of potassium hydroxide* a similar precipitate readily soluble in excess. This precipitate yields mere traces to *benzol* (absence of other alkaloids). Moistened with *nitric acid* the salt yields an orange-red coloration; with *test-solution of ferric*

* "Take of Morphia, in fine powder, *a troyounce;* Distilled Water *four fluidounces;* Muriatic Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water; then carefully drop in Muriatic Acid, constantly stirring, until the Morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper." *U. S.* 1870.

† According to Mr. D. B. Dott, the solubility of morphine hydrochlorate in rectified spirit at 60° F. is one in forty. (*P. J. Tr.*, 1887, 941.)

chloride a dull greenish-blue coloration. Heated on a water-bath for ten or fifteen minutes with a few drops of *sulphuric acid*, cooled, and treated with a few drops of *diluted nitric acid*, it gives a violet color rapidly passing to blood-red. It dissolves without coloration in strong *sulphuric acid;* the addition of a small quantity of *sodium arsenate* to a portion of this solution causes a bluish-green coloration, and a small quantity of *bismuth oxynitrate* added to another portion gives a purplish-brown coloration. It affords the reactions characteristic of hydrochlorides. 2 grammes of Morphine Hydrochloride dissolved in 250 cubic centimetres of warm *morphinated water*, with *solution of ammonia* added in the slightest possible excess, will give on cooling a crystalline precipitate which, when washed with a little cold *morphinated water* and dried, should weigh 1·51 grammes. The drying should be accomplished, first by pressing the precipitate between sheets of bibulous paper, then by exposing it to a temperature between 131° and 140° F. (55° and 60° C.), and finally to a temperature of 230° F. (110° C.) for twenty minutes. Heated to redness with free access of air, it burns, leaving no residue (absence of mineral impurities)." *Br.* A saturated solution in boiling water forms a solid crystalline mass on cooling. The solution of morphine hydrochlorate, when kept several months, has been known to produce vomiting, through the formation of traces of apomorphine. (*Pharm. Centralhalle*, 1885, 93.) The salt may be known to be a hydrochlorate by responding to the official test with silver nitrate. Potassa throws down from its solution a precipitate which is redissolved by an excess of the alkali. The salt is affected by heat, nitric acid, iodic acid, ferric chloride, and chlorine followed by ammonia, in the same manner as morphine. Sugar is said to have been used largely in the adulteration of this salt. It may be detected by Trommer's test. (See *Saccharum.*)

This preparation of morphine is much used in Great Britain, but in this country less than either the sulphate or the acetate. For medical properties, see *Morphina.*

MORPHINÆ SULPHAS. U. S. Morphine Sulphate.

(MÖR-PHĪ'NÆ SŬL'PHĂS.)

$(C_{17}H_{19}NO_3)_2.H_2SO_4+5H_2O$; 756·38. $(C_{17}H_{19}NO_3)_2.H_2SO_4.5H_2O$; 758.

Morphiæ Sulphas, *Br.* 1867, *U. S.* 1870; Morphinum Sulphuricum, *P. G.;* Sulphas Morphicus; Sulphate of Morphia; Sulfate de Morphine, *Fr.;* Schwefelsaures Morphin, *G.*

No process is given in the U. S. P. 1890: that of the U. S. P. 1870 is appended.* Morphine sulphate is no longer official in the British Pharmacopœia 1898, the hydrochloride being used in Great Britain almost exclusively.

In the process of 1870 the morphine is known to be saturated when it is wholly dissolved by the water. To ascertain whether the acid is added in excess, litmus paper may be resorted to. If the morphine employed contain narcotine, this will remain in the mother-liquor, and will not contaminate the product. The mother-liquor remaining after the first crystallization may be evaporated so as to afford a fresh supply of the sulphate; but, if the morphine was not originally quite pure, the second product will contain the impurities, and should not be used till it has undergone further preparation. When impure morphine is employed, the mother-liquor should be mixed with alcohol, or boiled with purified animal charcoal and filtered, and then decomposed by ammonia, which will precipitate the morphine. This may be converted into the sulphate in the manner directed by the Pharmacopœia.

Another mode of obtaining morphine sulphate is to dissolve the alkaloid in boiling alcohol of 36° Baumé (sp. gr. 0·8428), saturate it while hot with sulphuric acid, add purified animal charcoal, boil for a few minutes, and filter the solution at the boiling temperature. Upon cooling, it deposits most of the sulphate; and the remainder may be obtained by evaporating the mother-liquor. For an account by J. Calvert of the manufacture of morphine sulphate on the large scale, see *Proc. A. P. A.*, 1894, 650.

In the evaporation of the solution of this salt, care should be taken not to carry the heat too far; for, when pushed to incipient decomposition with an excess of acid, a new substance is formed containing no morphine. This salt is sometimes adulterated. Mr. D. B. Dott met with a sample in the English market which contained 34·63 per cent. of anhydrous sodium sulphate. (*P. J. Tr.*, August 4, 1877.)

* "Take of Morphia, in fine powder, *a troyounce;* Distilled Water *half a pint;* Diluted Sulphuric Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water, then carefully drop in Diluted Sulphuric Acid, constantly stirring until the Morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper." *U. S.* 1870.

Morphine sulphate crystallizes in beautifully "white, feathery, acicular crystals, of a silky lustre, odorless, and having a bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 21 parts of water, and in 702 parts of alcohol; in 0·75 part of boiling water, and in 144 parts of boiling alcohol; almost insoluble in ether. When heated for some time at 100° C. (212° F.), the salt loses 3 molecules (7·12 per cent.) of water of crystallization; the remaining 2 molecules (4·75 per cent.) are gradually expelled by raising the temperature to 130° C. (266° F.). At 255° C. (491° F.) the salt melts, and, upon ignition, it is consumed, leaving no residue. The salt is neutral to litmus paper. The addition of potassium or sodium hydrate test-solution to an aqueous solution of the salt causes a white precipitate, which is soluble in an excess of the alkali, and which conforms to the reactions and tests of Morphine (see *Morphina*). The aqueous solution yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid." *U. S.* By exposure to a heat of 120° C. (248° F.) it loses 9·66 parts of the water, but cannot be deprived of the remainder without decomposition. (*Liebig.*) The official tests for it are those for sulphuric acid and for morphine. Considerable discussion has taken place in the pharmaceutical journals about the solubility in water of morphine sulphate. Owing to the ease with which the salt parts with its water of crystallization, even at ordinary temperatures, it is not difficult to account for some of the discrepancies that exist in the text-books on this subject. Yet there can be no doubt that the heretofore commonly quoted solubility, "twice its weight of cold water," is an oft-repeated error. Prof. J. U. Lloyd (*N. R.*, May, 1882) found it soluble in 21·60 parts of cold water. Prof. F. B. Power, after a determination by precipitation with barium chloride, found a commercial specimen of undoubted purity to require very nearly 24 parts of cold water, and the U. S. P. 1880 has adopted his results. (*A. J. P.*, 1882, p. 97.) Virgil Coblentz subsequently examined five commercial samples, and practically confirmed Prof. Power's results, finding the specimens soluble respectively in 21·38, 23·90, 23·18, 17·69, and 18·97 parts of water. Mr. D. B. Dott criticises the methods employed by Prof. J. U. Lloyd, and to some extent those of Prof. Power, but fails to establish a very different result. (*P. J. Tr.*, 1882, p. 252.) The dose is from an eighth to a quarter of a grain (0·008–0·016 Gm.), which may be given in pill or in solution. The *solution of morphine sulphate* formerly official was made by dissolving 1 grain of morphine sulphate in 1 fluidounce of distilled water, and, although the solution is more stable than that of any other of the morphine salts in common use, it will in time become weakened through the presence of microscopic plants belonging to the Confervoideæ, and hence it is not desirable to keep it on hand. According to Prof. Hamberg, of Stockholm, the sulphate should be dissolved in boiling distilled water which is free from ammonia, phosphoric, nitric, and nitrous acids; the solution should be filtered through paper not previously moistened, and is best preserved in small well-filled vials closed with a glass stopper. (*Pharm. Zeitung*, No. 49; *A. J. P.*, 1881.) It is asserted by M. Vidal that the addition of chloral to a solution of morphine renders it much less liable to spontaneous change. This statement, if it be true, is important. He adds to the solution a quantity of chloral equivalent to twice the weight of the morphine it contains, and affirms that the injection of this mixture is not painful. For medical properties, see *Morphina* and *Morphinæ Acetas*, pp. 878, 880.

MORPHINÆ TARTRAS. Br. Morphine Tartrate.

(MÖR-PHĪ'NÆ TĂR'TRĂS.)

"Morphine Tartrate, $(C_{17}H_{19}NO_3)_2C_4H_6O_6.3H_2O$, may be prepared by the combination of morphine and tartaric acid in molecular proportions." *Br.*

This salt of morphine has been introduced into the British Pharmacopœia 1898; it was brought into notice by Erskine Stuart (1880), and recommended for hypodermic injection because of its greater solubility in water over the other salts of morphine. (See *Injectio Morphinæ Hypodermica*, p. 738, and *Liquor Morphinæ Tartratis*, p. 812.) It is officially described as "A white powder consisting of fine nodular tufts of minute acicular crystals. Efflorescent at 68° F. (20° C.). Soluble in 11 parts of cold *water*, almost insoluble in *alcohol* (90 per cent.). It affords the reactions characteristic of morphine and of tartrates. 2 grammes dissolved in 20 cubic centimetres of warm *morphinated water*, with *solution of ammonia* added in the slightest possible excess, will give, on cooling, a crystalline precipitate which, after washing and drying as described under 'Morphinæ Hydrochloridum,' should weigh 1·47 grammes. Heated to redness with free access of air, it burns without leaving any residue (absence of mineral impurities)." *Br.*

MOSCHUS. U. S., Br. Musk.

(MŎS'ĈHŬS.)

"The dried secretion from the preputial follicles of Moschus moschiferus, Linné (class, Mammalia; order, Ruminantia)." *U. S.* "The dried secretion from the preputial follicles of Moschus moschiferus, Linn." *Br.*

Musc, *Fr.;* Bisam, Moschus, *G.;* Muschio, *It.;* Almizcle, *Sp.*

Gen. Ch. Horns none. *Fore teeth* eight in the lower jaw. *Tusks* one on each side, in the upper jaw, projecting out of the mouth.

Moschus moschiferus. Gmelin, *Syst. Nat.* i. 172; *Rees's Cyclopædia.* This animal bears a close resemblance to the deer in shape and size. It is usually about three feet in length and two feet high, with haunches considerably more elevated than the shoulders. From its upper jaw two tusks project downward out of the mouth, each about two inches long, curved backward, and serving to extract the roots which are used as food by the animal. The ears are long and narrow, and the tail very short. The fleece, consisting of strong, elastic, undulated hairs, varies in color with the season, the age of the animal, and perhaps the place which it inhabits. The general color is a deep iron-gray. The individual hairs are whitish near the root, and fawn-colored or blackish towards the tip. The musk is contained in an oval, hairy, projecting sac, found only in the male, situated between the umbilicus and the prepuce, from two to three inches long, and from one to two broad, opening by a small hairy orifice at its anterior part, and marked posteriorly by a groove or furrow which corresponds with the opening of the prepuce. It is lined internally by a smooth membrane, thrown into a number of irregular folds, forming incomplete partitions. In the vigorous adult animal, the sac sometimes contains six drachms of musk; but in the old, seldom more than two drachms, and none in the young.* The musk is secreted by the lining membrane, and in the living animal forms a consistent mass, which on the outside is compact, and marked with the folds of the membrane, but is less firm towards the centre, where there is sometimes a vacant space. As first secreted it is probably liquid, and a portion is occasionally forced out by the animal, to which it communicates its odor. The musk-deer inhabits the vast mountainous regions of Central Asia, extending from India to Siberia, and from the country of the Turcomans to China. It is an active and timid animal, springing from rock to rock with surprising agility, and frequenting the snowy recesses and most inaccessible crags of the mountains. Concealing itself during the day, it chooses the night for roaming in search of food, and, though said to be abundant in its native regions, is taken with difficulty. It is hunted for its hide, as well as for the musk. The natives often take it by snaring. As soon as the animal is killed, the sac is cut off, dried, and sent into the market.† It has been calculated that about twenty thousand deer, male and female, are annually killed.

Musk varies in quality with the country inhabited by the animal. That procured from the mountains on the southern borders of Siberia, and brought into the market through Russia, is comparatively feeble. Chinese musk has been said to come from Tonquin, but appears really to be chiefly obtained in Yun-Nan, a province in the extreme south of China, whence it is sent 1400 miles to Shanghai, the export centre. A variety intermediate between these is procured in the Himalaya Mountains and Thibet and sent to Calcutta. This is sometimes enclosed in the membranous lining of the sac, without the hairy envelope, and in this condition is said to be quite equal if not superior to that surrounded by the skin, as in the former condition it dries readily in the sun, while in the latter the aid of artificial heat is deemed necessary, by which the musk may sometimes be injured. (F. Peake, *P. J. Tr.*, Feb. 1861.) A musk which is also said to pass from Thibet into China is *Cabardine* musk. (See *Chemist and Druggist*, 1890.)

Two varieties are known in commerce, the *Chinese*, *Thibet* or *Tonquin* musk, and *Russian* or *Siberian* musk.‡ Both come in sacs, convex and hairy on one side, flat and destitute of hair

* According to Col. Frederick Markham, as much as two ounces are sometimes found, and the average for a full-grown animal is an ounce; but, as many of the deer are killed young, the pods in the market do not contain more than half an ounce upon an average. He states that the musk of the younger animals is not so strong as that of the old, but is much pleasanter. (*P. J. Tr.*, xv. 472.)

† Attention has been drawn by Dr. E. Bertherand to the excrement of the *Algerian gazelle, Antilope dorcas*, L., which possesses a powerful musk-like odor. It is said to contain about 7 per cent. of an acid resin (?) of a musky odor. (*Proc. A. P. A.*, xxvi. 332.)

‡ *American Musk.* Owing to the costliness of true musk, the sacs derived from *Fiber zibethicus*, the common musk-rat, have been used as a substitute. This product possesses many of the properties of musk, and, although the odor is not identical, it can often replace it in perfumery if used judiciously. If the fatty matter present has become rancid, it should be washed out by agitating the bruised sacs with a little ether and pouring it off, and allowing the musk to become dry by exposure to the air.

on the other. The hairs are brownish-yellow, grayish, or whitish, stiff and short, and arranged concentrically around the orifice of the sac. The Chinese, which is the most highly valued, is in bags of a rounder shape, covered with brownish-yellow or reddish-brown hairs, and containing at most a drachm and a half of large-grained, dark, strong-scented musk, of an ammoniacal odor. The Russian is in longer and larger bags, small-grained, of a light yellowish-brown color, and of a weaker and more fetid odor, with less smell of ammonia.

Properties. Musk is in grains or lumps concreted together, soft and unctuous to the touch, and of a reddish-brown or ferruginous color resembling that of dried blood. Some hairs of the pod are generally mixed with it. It is officially described as "in irregular, crumbly, somewhat unctuous grains, dark reddish-brown, having a peculiar, penetrating and persistent odor, and a bitterish taste. It is contained in oval or roundish sacs about 4 to 5 Cm. in diameter, on one side invested with a smoothish membrane, on the other side covered with stiff, appressed, grayish hairs, concentrically arranged around two orifices near the centre. About 10 per cent. of Musk is soluble in alcohol, the tincture being light brownish-yellow, and on the addition of water becoming slightly turbid. About 50 per cent. of Musk is soluble in water, the solution being deep brown, faintly acid, and strongly odorous. When ignited with free access of air, Musk gives off a peculiar, somewhat urinous odor, and leaves behind not more than 8 per cent. of a grayish ash." *U. S.* The odor is strong, penetrating, and so diffusive that one part of musk communicates its smell to more than 3000 parts of inodorous powder. (*Fée.*) In some delicate individuals it produces headache and other disagreeable symptoms, and it has even caused convulsions. The taste is bitter, disagreeable, and somewhat acrid. The color of the powder is reddish-brown. Musk is inflammable, burning with a white flame, and leaving a light spongy charcoal. Reduced to ashes, it leaves about 5 per cent. of residue, containing potassa, lime, magnesia, iron, carbonic, phosphoric, and sulphuric acids, chlorine, and traces of potassium ferrocyanide and ammonium sulphide. (*W. Bernatzik.*) It yields, upon analysis, a great number of proximate principles. Guibourt and Blondeau obtained water, ammonia, stearin, olein, cholesterin, an oily acid combined with ammonia, volatile oil, ammonium chloride, potassium and calcium chlorides, an uncertain acid combined with ammonia, potassa, and lime, gelatin, albumen, fibrin, a highly carbonaceous matter soluble in water, a soluble calcareous salt with a combustible acid, calcium carbonate and phosphate, hair, and sand. (*Ann. de Chim. et de Phys.*, ix. 327.) Besides these constituents, Geiger and Reinman found a peculiar bitter resin, a peculiar substance in part combined with ammonia, and lactic acid both free and in combination. According to Guibourt and Blondeau, it contains 47 per cent. of volatile matter, thought by some to be chiefly ammonia, by others to be a compound of ammonia and volatile oil. Theimann obtained only from 10 to 15 per cent. But the quantity of volatile as well as of soluble matter varies exceedingly in different specimens. Thus, Theimann found from 80 to 90 per cent. of matter soluble in water, Buchner only 54·5 per cent., and other chemists intermediate proportions. The proportion soluble in alcohol, as ascertained by different experimenters, varies from 25 to 62 per cent. Ether is a good solvent. The aqueous infusion has a yellowish-brown color, a bitterish taste, a strong smell, and an acid reaction. The alcoholic tincture is transparent, and of a reddish-brown color, with the peculiar odor of musk. The action of potassa upon musk is accompanied with the extrication of ammonia and an increase of its peculiar odor. By the influence of heat and moisture long continued, ammonia is developed, which acts upon the fatty matter, producing a substance resembling adipocere, but, according to Guibourt, without diminishing the medicinal activity. The correctness of this opinion, however, is perhaps questionable; and it is advisable to preserve the musk as much as possible unaltered. When kept in glass bottles, in a situation neither moist nor very dry, it remains for a great length of time without material change. The odor of musk is very much diminished by mixing it with emulsion or syrup of bitter almond, or with cherry-laurel water. From the experiments of Wimmer, it appears that musk loses its odor when rubbed with kermes mineral, or golden sulphide of antimony, and reacquires it on the addition of a little solution of ammonia. (*Pharm. Centralbl.*, 1843, 406.) Camphor rubbed up with musk is also said to destroy its odor. (See *Artificial Musk*, PART II.)

Adulterations. The price of this medicine is so high, and its sources are so limited, as to offer strong temptations to adulteration; and little genuine unmixed musk is to be found in the market. The sophistication commences in China, and is completed in Europe and this country. A common practice in the East is to open the sac and to supply the place of the musk with an adulterated mixture. Sometimes the scrotum of the animal is filled with this mixture, and not unfrequently the sacs are made out of the skin. Dried blood, from its re-

semblance to musk, is one of the most common adulterations; but, besides this, sand, lead, iron filings, hair, animal membrane, tobacco, the dung of birds, wax, benzoin, storax, asphaltum, artificial musk, and other substances are introduced. These are mixed with a portion of musk, the powerful odor of which is diffused through the mass and renders the discovery of the fraud sometimes difficult. It is said that the Chinese sometimes mix the musk of Tonquin with that of Siberia. The bags containing the drug should have the characters before described as belonging to the natural sac, and should present no evidence of having been opened. The slit is sometimes carefully sewed up, sometimes glued together. The former condition may be discovered by close inspection, the latter by immersion in hot water. When the bag is made from any other portion of the skin, the difference may be detected, according to Mr. Neligan, by a microscope which magnifies 300 diameters. The genuine hairs exhibit innumerable cells, which are wanting in the spurious. (*Chem. Gaz.*, Feb. 1846, p. 79.) Musk which burns with difficulty, has a feeble odor and a color either pale or entirely black, feels gritty to the finger, is very moist so as to lose much weight in drying, or contains obvious impurities, should be rejected. Russian musk is said never to be adulterated before leaving Russia.* "Musk should be free from earthy impurities, and should on incineration yield not more than 8 per cent. of ash." *Br.*

Medical Properties and Uses. Musk is stimulant and antispasmodic, in some way stimulating very decidedly the nervous centres when exhausted, without producing either in health or in disease any very pronounced symptoms. It is a very valuable remedy in the treatment of nervous exhaustion coming on at or about the crisis of acute disease. When, in low cases of *typhus affections*, subsultus tendinum, tremors, singultus, and similar symptoms indicate the failure of nerve-power, its exhibition is often of great advantage. We have seen it apparently save life in the acme of *typhoid fever*, when the vital powers seemed to have almost succumbed, and when violent alterations of temperature or symptoms resembling those of coma vigil had manifested themselves. It was many years ago especially commended by Prof. Trousseau in the treatment of *adynamic pneumonia* of drunkards with severe cerebral symptoms. Under these circumstances it certainly appears to do great good. In very obstinate *hiccough* it is one of the most efficient of our remedies; and, according to the late Dr. G. B. Wood, it is very effective in those alarming *convulsions of infants* originating in spasm of the intestines. In the *laryngismus stridulus* or crowing disease of infants, M. Bouchut relied mainly on musk, having found it more efficacious than any of the narcotics. (*N. Y. Med. Journ.*, Sept. 1868, p. 545.) According to our experience, musk rapidly loses its power of influencing the nerve-centres, and for this reason, and on account of its costliness, its employment should always be delayed until severe nervous exhaustion becomes alarming. Musk was unknown to the ancients. Aëtius was the first writer who noticed it as a medicine. It was introduced into Europe through the Arabians, from whose language its name is derived. It may be given in the form of pill or emulsion. In preparing mixtures of musk, it is recommended to rub the musk up first with a very little boiling water containing a trace of solution of potassa, afterwards with a larger quantity, and to add the liquid thus prepared to whatever mixture may be prescribed. The insolubility of musk in cold water, and its much greater solubility in that liquid when boiling hot, render this mode of preparation much preferable to rubbing up with cold water. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 291.) The medium dose is ten grains (0·65 Gm.), to be repeated every two or three hours. It may often be administered with great advantage in the form of enema.

MUCILAGINES. Mucilages.

(MŪ-CĮ-LĂǴ'Į-NĒȘ.)

Mucilages, *Fr.;* Schleime, *G.*

Mucilage, in the ordinary acceptation of the term, and in the sense in which it is employed in the U. S. Pharmacopœia, is an aqueous solution of gum, or of substances closely allied to it. In the British Pharmacopœia the term is applied also to the semi-liquid, jelly-like substance resulting from the cooling of a hot solution of starch.

* For an account of the effects of numerous reagents on musk, and other modes of identification, as well as of detecting adulterations, see a paper by Prof. W. Bernatzik, in *A. J. P.*, 1861, p. 427. There is a discrepancy between Prof. Bernatzik's statement of the solubilities of musk and that of the text. According to the latter, ether is a good solvent; according to the former, ether and chloroform possess scarcely any solvent power.

MUCILAGO ACACIÆ. U. S., Br. Mucilage of Acacia.

(MŪ-CĮ-LĀ'GŌ Ą-CĀ'CĮ-Æ.)

Mucilago Gummi Arabici, *P. G.;* Mucilage of Gum Arabic; Mucilage de Gomme arabique, Mucilage arabique, *Fr.;* Gummischleim, *G.*

"Acacia, in small fragments, *three hundred and forty grammes* [or 11 ounces av., 435 grains]; Water, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Wash the Acacia with cold Water, and let it drain. Then add to it enough Water to make the mixture weigh *one thousand grammes* [or 35 ounces av., 120 grains], agitate or stir occasionally until the Acacia is dissolved, and strain. Keep the product in well-stoppered, completely filled bottles, in a cool place." *U. S.*

"Gum Acacia, in small pieces, 4 *ounces* (Imperial) or 100 grammes; Distilled Water, *a sufficient quantity*. Rapidly rinse the Gum Acacia with a little Distilled Water; then dissolve it in *six fluid ounces* (Imp. meas.) or one hundred and fifty cubic centimetres of Distilled Water in a closed vessel and strain." *Br.*

The gum used for this purpose should be in small fragments or coarse powder, as it is more readily dissolved in this state than when finely pulverized. Straining is necessary to separate the foreign substances which are often mixed with gum arabic. This mucilage is semi-transparent, almost colorless if prepared from good gum, viscid, tenacious, of a feeble peculiar odor, and nearly tasteless. If the solution of gum should be colored, it may be rendered colorless by the addition of a concentrated solution of chlorine; and by boiling for about half an hour, so as to drive off the chlorine and hydrochloric acid, it may be rendered fit for use. (*Guérin.*) By straining a solution of gum through a layer of freshly precipitated alumina it can be almost entirely decolorized, particularly if the operation be repeated several times. By keeping, mucilage becomes sour, in consequence of the spontaneous generation of acetic acid; and this happens even though it be enclosed in well-stopped bottles; but, according to Guérin, the solution of pure gum undergoes no change in vacuo. Heat in its preparation is said to favor the production of acid; and hence cold has been substituted for boiling water in the present formulas. According to R. Rother (*A. J. P.*, xliv. 113), if glycerin be employed in the proportion of one to eight of the mass, and the mixture of water and it be added to the gum in a bottle and solution secured by agitation at intervals over several hours, the resulting mucilage does not spoil: the presence of glycerin is objectionable, however, for many of the uses of mucilage of acacia. E. D. Oesch (*West. Drug.*, 1892, 38) adds about 6 per cent. of alcohol as a preservative. Kellar preserves the mucilage by the addition of acetanilid (two grains in the fluidounce). (*Chem. and Drug.*, 1896, 378.) Archer & Co. have found (*A. J. P.*, xlvi. 469) that if "Tolu water" be substituted for water the mucilage will keep for months. The Tolu water is made by rubbing two drachms of the tincture with magnesium carbonate and two pints of water, and filtering. Mucilage is employed chiefly in the making of pills, and in suspending insoluble substances in water. In prescribing it for mixtures, it should be recollected that it is a solution of definite strength, containing, according to the U. S. formula, half an ounce of the gum to each fluidounce of mucilage. The British mucilage is a little stronger. Half a fluidounce is usually sufficient for a six- or eight-ounce mixture. The adhesiveness of the mucilage is stated to be very much increased by the addition of one part of aluminum sulphate to one hundred and twenty-five parts of the mucilage.

MUCILAGO SASSAFRAS MEDULLÆ. U. S. Mucilage of Sassafras Pith.

(MŪ-CĮ-LĀ'GŌ SĂS'SĄ-FRĂS MĘ-DŬL'LÆ.)

Mucilage de Moëlle de Sassafras, *Fr.;* Sassafrasmark-Schleim, *G.*

"Sassafras Pith, *two grammes* [or 31 grains]; Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Macerate the Sassafras Pith in the Water during three hours, and strain. This preparation should be freshly made, when wanted." *U. S.*

This mucilage may be prepared in a much shorter time, if the pith be broken into small fragments and the mixture often agitated. When a thicker mucilage is desired, J. W. England recommends beating the pith with sterilized water in a mortar until pasty, expressing through coarse muslin, returning the residue, and continuing the process until a thick mucilage is obtained. (*A. J. P.*, 1894, 350.) It is much used as an application to the eye in *conjunctivitis.* It may be taken as a drink *ad libitum* in *inflammations of the mucous passages.*

MUCILAGO TRAGACANTHÆ. U. S., Br. Mucilage of Tragacanth.

(MŪ-CĮ-LĀ'GŌ TRĂG-Ą-CĂN'THÆ.)

Mucilage de Gomme adragante, Mucilage adragant, *Fr.;* Traganthschleim, *G.*

"Tragacanth, *six grammes* [or 93 grains]; Glycerin, *eighteen grammes* [or 278 grains]; Water *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the Glycerin with *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims] of Water in a tared vessel, heat the mixture to boiling, add the Tragacanth, and let it macerate during twenty-four hours, stirring occasionally. Then add enough Water to make the mixture weigh *one hundred grammes* [or 3 ounces av., 231 grains], beat it so as to make it of uniform consistence, and strain it forcibly through muslin." *U. S.*

"Tragacanth, in powder, 60 *grains* (Imperial) or 5·5 grammes; Alcohol (90 per cent.), 2 *fl. drachms* (Imp. meas.) or 10 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the Tragacanth with the Alcohol in a bottle; add a sufficient quantity of Distilled Water to form *ten fluid ounces* (Imp. meas.) or four hundred cubic centimetres, and shake immediately." *Br.*

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. The addition of glycerin renders it more serviceable as an excipient. From its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water. When kept long, it is apt to undergo decomposition, and to become offensive, but it will keep well if enough carbolic acid be added to impart its characteristic odor faintly. (*A. J. P.*, 1864.) The alcohol in the British process facilitates the quick production of the mucilage, and in addition acts as a preservative.

MUCILAGO ULMI. U. S. Mucilage of Elm.

(MŪ-CĮ-LĀ'GŌ ŬL'MĪ.)

Mucilage of Slippery Elm Bark; Mucilage d'Ecorce d'Orme fauve, *Fr.;* Ulmenrinden-Schleim, *G.*

"Elm, bruised, *six grammes* [or 93 grains]; Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Digest the Elm with the Water, on a water-bath, in a covered vessel, during one hour, then strain. This preparation should be freshly made, when wanted." *U. S.*

This may be used *ad libitum* as a demulcent and nutritious drink in *catarrhal and nephritic diseases*, and in *inflammatory intestinal affections*. It is much employed locally as a soothing application to *boils* and *carbuncles*, and as a demulcent in *dermatitis*, *erysipelas*, etc.

MYRISTICA. U. S., Br. Nutmeg.

(MĪ-RĬS'TĮ-CĄ.)

"The seed of Myristica fragrans, Houttuyn (nat. ord. Myristicaceæ), deprived of its testa." *U. S.* "The dried seed of Myristica fragrans, Houtt., divested of its testa." *Br.*

Semen Myristicæ, *P. G.;* Nux Moschata, Muscade, Noix muscade, *Fr.;* Muskatnuss, *G.;* Noce moschata, *It.;* Nuez moscada, *Sp.*

Myristica fragrans. Houttuyn, *Nat. Hist.* vol. ii., part iii., 333; *B. & T.* 218.*—*M. moschata.*

* Various species of the genus Myristica, other than those spoken of in the text, yield commercial seeds or products:

Ucuhula nut is a round or oval seed of *Myristica surinamensis*. It is one-half to two-thirds of an inch in diameter, light brown, but usually covered by a blackish, thin, friable testa. Internally it resembles the nutmeg, but is distinguished by the presence of extraordinarily large and handsome albuminous crystalloids. These seeds are said to contain over 70 per cent. of a solid yellow fat, melting at 36° C. (See *A. J. P.*, 1886; also *Arch. de Pharm.*, July, 1888.) The kernel of the fruit of the Brazilian *Myristica officinalis, Mart.* (*M. bicuhiba, Schott*), resembles the nutmeg in form and structure, but is covered with a black shell marked with broad furrows. It contains crystals like those above spoken of, but less splendid and regular, and apt to be in three forms. It yields a fat (*bicuhiba fat*, or *bicuhiba balsam*) very much like that of the ordinary nutmeg, but having a rather sour, sharp taste, melting at 47° F. It contains a peculiar fatty acid, *bicuhibastearic* acid. The *otoba fat* is the product of the fruit of *Myristica otoba*. It is almost colorless, when fresh has a nutmeg-like odor, melts at 38° C., and contains *myristin*, *olein*, and *otobite*. The latter principle crystallizes in shiny, colorless crystals, melting at 133° C. The fruit of *Virola sebifera, Aubl.* (*s. Myristica sebifera, Lam.*), also yields a fatty substance which is known as *ocuba wax*. The so-called *California nutmeg* is not a nutmeg at all, but the seed of a coniferous tree, *Torreya californica*. It is oblong, with a smooth, brownish, thin testa, and affords a marbled cross-section. Its odor and taste are terebinthinate. Neither are the *Jamaica* or *calabash nutmeg*, from *Monodora myristica*, the *New Holland* or *plume nutmeg*, from *Atherosperma moschata*, and the *clove nutmeg*, from *Agathophyllum aromaticum*, true nutmegs.

Thunberg; Willd. *Sp. Plant.* iv. 869.—*M. officinalis.* Linn. *Suppl.* 265; Lindley, *Flor. Med.* 21. The nutmeg-tree is about thirty feet high, with numerous branches, and an aspect somewhat resembling that of the orange-tree. The leaves stand alternately on short footstalks, are oblong-oval, pointed, entire, undulated, obliquely nerved, bright green and somewhat glossy on their upper surface, whitish beneath, and of an aromatic taste. The flowers are male and female upon different trees. The former are disposed in axillary, peduncled, solitary clusters; the latter are single, solitary, and axillary; both are minute and of a pale yellowish color. The fruit, which appears on the tree mingled with the flowers, is round or oval, of the size of a small peach, smooth, at first pale green, but yellow when ripe, and marked with a longitudinal furrow. The external covering, which is at first thick and fleshy and abounds in an austere, astringent juice, afterwards becomes dry and coriaceous, and, separating into two valves from the apex, discloses a scarlet reticulated membrane or arillus, commonly called *mace*, closely investing a thin, brown, shining shell, which contains the kernel or *nutmeg*. The nutmeg-tree is a native of the Moluccas and other neighboring islands, and abounds especially in that small cluster distinguished by the name of Banda, whence the chief supplies of nutmegs were long derived. But numerous varieties of the plant are now cultivated in Sumatra, Java, Singapore, Penang, Ceylon, and other parts of the East Indies, and have been introduced into the Isles of France and Bourbon, Cayenne, and several of the West India islands. The larger part of the nutmegs of commerce is, however, said still to come from the Dutch Banda Islands. The Penang nutmegs are distinguished by not being limed. The tree is produced from the seed. It does not flower until the eighth or ninth year; after which it bears flowers and fruit together, without intermission, and is said to continue bearing for seventy or eighty years. Little trouble is requisite in its cultivation. A branch of the female tree is grafted into all the young plants when about two years old, so as to insure their early fruitfulness. In the Moluccas the tree yields three crops annually. The fruit is gathered by hand, and the outside covering rejected. The mace is then carefully separated, so as to break it as little as possible, is flattened, dried in the sun, and afterwards sprinkled with salt water, with the view of contributing to its preservation. Its fine red color is much impaired by drying. The nuts are dried in the sun or by ovens, and exposed to smoke till the kernel rattles in the shell. They are then broken open; and the kernels, having been removed and steeped for a short time in a mixture of lime and water, probably in order to preserve them from the attacks of worms, are next cleaned, and packed in casks or chests for exportation. Dr. Lumsdaine has found them to keep better if rubbed over with dry lime than when prepared in the moist way. (See *Am. Journ. of Science and Arts*, Nov. 1851.) Nutmegs are brought to this country either directly from the East Indies or indirectly through England and Holland. They are also occasionally imported in small quantities from the West Indies.

The amount of unground nutmegs imported into the United States for the year ending June 30, 1897, was 1,669,740 pounds, valued at $451,614. (*U. S. Bureau of Statistics*, 1898.)

Properties. The nutmeg (*nux moschata*) is of a roundish or oval shape, obtuse at the extremities, marked with vermicular furrows, of a grayish color, hard, smooth to the touch, yielding readily to the knife or the grater, but not very pulverulent. When cut or broken it presents a yellowish surface, varied with reddish-brown, branching, irregular veins, which give to it a marbled appearance. These dark veins abound in oily matter, upon which the medicinal properties depend. The odor of nutmeg is delightfully fragrant, the taste warm, aromatic, and grateful. Its virtues are extracted by alcohol and ether. Clifford Richardson (*Bulletin U. S. Department of Agriculture*, No. 13, 1887) gives as the average of three analyses of imported nutmegs: water, 5·56 per cent.; ash, 2·88; volatile oil, 3·23; fixed oil or fat, 34·22; starch, etc., 39·62; crude fibre, 9·21; albuminoids, 5·28: total, 100·00. The *volatile oil* is obtained by distillation with water. (See *Oleum Myristicæ*.)

Under the names of *long*, *female*, or *wild nutmeg*, *Macassar nutmeg*, *Papua nutmeg*, *New Guinea nutmeg*, *horse nutmeg*, certain seeds have long been known in European commerce, and have finally become an important article of trade, nearly 77,000 kilos of them having been sold in Holland in the year 1894. These seeds have been variously ascribed to *M. fatua* Houtt. (*M. tomentosa* Thunb., *M. macrophylla* Roxb.) and other species of the genus Myristica, but by Bassermann and Warburg have in all their varieties been traced to the *M. argentea* Warburg, of New Guinea, from which country they are often taken to Macassar to finally enter commerce as Macassar nutmegs. The numerous varieties of these false nutmegs are readily reducible to two, which differ chiefly in size, the largest being commonly known as the Papua nuts, the smaller as the Macassar nuts. They are distinguished from the true nutmeg by their

greater length, their elliptical shape, their comparatively feeble odor and disagreeable taste, and by the absence of the dark brown veins.

Nutmegs have been punctured and boiled in order to extract their essential oil, and the orifice afterwards closed so carefully as not to be discoverable unless by breaking the kernel. The fraud may be detected by their levity. They are also apt to be injured by worms, which, however, attack preferably the parts least impregnated with the volatile oil. The Dutch were formerly said to heat them in a stove in order to deprive them of the power of germinating and thus prevent the propagation of the tree. The largest nutmegs now command the highest prices. They should be rejected when very light in weight, with a feeble taste and smell, worm-eaten, musty, or marked with black veins.

The *concrete* or *expressed oil of nutmeg* (*Oleum Myristicæ Expressum*, Br.), commonly called *oil of mace*, or *nutmeg butter*, is obtained by bruising nutmegs, exposing them in a bag to steam, and then compressing them strongly between heated plates. A liquid oil flows out, which becomes solid when it cools. Nutmegs are said to yield from 10 to 12 per cent. of this oil, but Flückiger and Hanbury obtained as much as 28 per cent.* (See analyses of Richardson, quoted previously.) The best is imported from the East Indies in stone jars, or in rectangular blocks 10 inches long by 2½ inches wide, wrapped in palm leaves. It is solid, soft, unctuous to the touch, of a yellowish or orange-yellow color more or less mottled, with the odor and taste of nutmeg. It is composed, according to Schrader, of 52·09 per cent. of a soft oily substance, yellowish or brownish, soluble in cold alcohol and ether; 43·75 of a white, pulverulent, inodorous substance, insoluble in these liquids; and 4·16 of volatile oil. The pulverulent constituent, which received from Playfair the name of *myristin*, has a silky lustre, melts at 31° C. (88° F.), and yields on saponification glycerin and *myristic acid*, $C_{14}H_{28}O_2$. Myristin, $C_3H_5(OC_{14}H_{27}O)_3$, is a true fat, or *glyceryl myristate*. It is also found in spermaceti, in cocoanuts, and in the fixed oil of linseed and poppy oil. It may be obtained directly from nutmeg by exhausting it by means of benzol, filtering the liquid, and allowing it to crystallize by spontaneous evaporation. To purify the product, it may be dissolved in a mixture of two parts of absolute alcohol and three of benzol with the aid of heat, then filtering the liquid while hot, and setting it aside. On cooling, it deposits the pure myristin in crystals. (*Journ. de Pharm.*, Juin, 1859, p. 471.) Analyzed by Koller, the expressed oil was found to contain, in 100 parts, 6 of a volatile oil analogous to the oil of mace, 70 of myristin, 20 of olein, 3 of resin, and 1 of salts, etc. (*Arch. der Pharm.*, clxxiii. 280.) Wallach found in the volatile oil *pinene* and *dipentene* of the class of terpenes, and Semmler found *myristicol*, $C_{10}H_{16}O$, which is liquid, and *myristicin*, a solid ester of the composition $C_{12}H_{14}O_3$. An inferior kind of the oil is prepared in Holland, and sometimes found in commerce. It is in hard, shining, square cakes, lighter-colored than that from the East Indies, and with less smell and taste. It is supposed to be derived from nutmegs previously deprived of most of their volatile oil by distillation. An artificial preparation is sometimes sold for the genuine oil. It is made by mixing various fatty matters, such as suet, palm oil, spermaceti, wax, etc., adding some coloring substance, and giving flavor to the mixture by the volatile oil.

Medical Properties and Uses. Nutmeg unites to the medicinal properties of the ordinary aromatics considerable narcotic power. In the quantity of two or three drachms (7·8 or 11·65 Gm.), it has been known to produce stupor and delirium; and dangerous if not fatal consequences are said to have followed its free use in India. For cases, see *A. J. P.*, 1855; *Brit. Med. Journ.*, Dec. 1889; also *Lancet*, Jan. 19, 1895. Dr. H. C. Wood found in experiments upon the lower animals that the oil of nutmeg is a powerful narcotic, with very much less sedative influence upon the heart than is possessed by most volatile oils. Injected into the circulation of the dog, it caused profound sleep, with slowing of the respiration, and, if the dose had been large enough, loss of reflex activity. Nutmeg is usually employed to cover the taste or correct the operation of other medicines, but more frequently as an agreeable addition to farinaceous articles of diet, and to various kinds of drink in cases of languid appetite and delicate stomach. It is usually given in substance, and is brought by grating to the state of a powder. *Mace* possesses properties essentially the same as those of nutmeg, and has caused alarming sensorial disturbance. (G. C. Watson, *Prov. Med. and Surg. Journ.*, Jan. 26,

* A process for obtaining it by means of carbon disulphide has been proposed by M. Lepage, of Gisors, in France, and has received the sanction of the Society of Pharmacy of Paris. It consists in treating the nutmeg, thoroughly comminuted, with three times its weight of the well-rectified liquid referred to, agitating the mixture frequently for 24 hours, expressing, repeating the process with two parts only of the menstruum, mixing the products of the two macerations, filtering in a covered vessel, and then distilling off the disulphide until the residue is entirely deprived of the menstruum. (*Journ. de Pharm.*, 3e sér., xxxi. 28.)

1848.) It is, however, less used as a medicine. The dose of either is from five to twenty grains (0·33–1·3 Gm.). The volatile oil may be substituted, in the dose of from two to five drops (0·10–0·25 C.c.). The expressed oil is occasionally used as a gentle external stimulant, and is an ingredient in the *Emplastrum Picis* of the British Pharm. 1885. The ancients were wholly unacquainted with the nutmeg; and Avicenna is said to be the first author by whom it was noticed.

MYRRHA. U. S., Br. Myrrh.

(MĬR'RHĄ.)

"A gum-resin obtained from Commiphora Myrrha (Nees), Engler (nat. ord. Burseraceæ)." *U. S.* "A gum-resin obtained from the stem of Balsamodendron Myrrha, Nees, and probably other species." *Br.*

Gummi-Resina Myrrha; Myrrhe, *Fr., G.;* Mirra, *It., Sp.;* Murr, *Ar.;* Bowl, *Hindost.*

Though myrrh has been employed from the earliest times, it is still uncertain by what plant it is yielded. The *Amyris kataf* of Forskhal, seen by that traveller in Arabia, was supposed by him to be the myrrh-tree, but without sufficient proof. Afterwards Ehrenberg met on the frontiers of Arabia Felix with a plant from the bark of which he collected a gum-resin precisely similar to the myrrh of commerce. From specimens of the plant taken by Ehrenberg to Germany, Nees von Esenbeck referred it to the genus Balsamodendron of Kunth, and named it *Balsamodendron myrrha.* This genus was formed by Kunth from *Amyris*, and includes the *Amyris kataf* of Forskhal, which may possibly also produce a variety of myrrh.* The new genus differs from *Amyris* chiefly in having the stamens beneath instead of upon the germ. It was not thought by De Candolle sufficiently distinct. Berg found another species in Ehrenberg's collection, to which was attached a label by the discoverer, stating that he had collected myrrh from it, and proposed to call it *Balsamodendron ehrenbergianum.* (*A. J. P.*, 1873, 314.) Both Oliver and Trimen agree that this plant is not specifically distinct from *B. opobalsamum.* The belief that myrrh is the product of *B. myrrha* has been confirmed by the German traveller Hildebrand, who collected the plant in 1873, in the Adel Mountains, on the north Somali coast (*P. J. Tr.*, 3d ser., ix. 893); but the opinion is held that much of the myrrh of commerce is the product of *B. ehrenbergianum*, or of other non-official species. Deflers and Schweinfurth (*Ber. d. Pharm. Ges. zu Berlin*, 1893) believe that the genuine myrrh is yielded by *Commiphora abyssinica* (Berg.) Engl., which is found in Southern Arabia, Erithrea, and Northern Abyssinia. *C. Schimperi* (Berg.) Engl., occurring in the Yemen, Abyssinia, and from Kern to Tigré, is likely also to yield some of the commercial Arabian myrrh. *C. Myrrha* (Nees) Engl. does not apparently produce any myrrh, although Hildebrand states that a plant of the Somali region resembling *C. myrrha*—but probably a distinct species, *C. Playfairii* (Hook. f.) Engl.—yields naturally myrrh. On the other hand, the director of the Kew Gardens believes that myrrh is yielded by *C. myrrha* and *C. simplicifolia*, while E. M. Holmes is of the opinion that Arabian myrrh is the product of *Balsamodendron myrrha.*

Balsamodendron myrrha. Fée. *Cours d'Hist. Nat. Pharm.* i. 641; Carson, *Illust. of Med. Bot.* i. 28, pl. 20; *B. & T.* 60. This is a small tree, with a stunted trunk, covered with a whitish-gray bark, and furnished with rough abortive branches terminating in spines. The leaves are ternate, consisting of obovate, blunt, smooth, obtusely denticulate leaflets, of which the two latter are much smaller than the one at the end. The fruit is oval-lanceolate, pointed, longitudinally furrowed, of a brown color, and surrounded at its base by the persistent calyx. The tree grows in Arabia Felix, in the neighborhood of Gison, in dwarfish thickets, interspersed among the Acaciæ and Euphorbiæ. The juice concretes spontaneously upon the bark.

Formerly the best myrrh was brought from the shores of the Red Sea by way of Egypt and the Levant, and hence received the name of *Turkey myrrh;* while the inferior qualities were imported from the East Indies, and commonly called *India myrrh.* These titles have ceased to be applicable, as myrrh of all qualities is now brought from the East Indies, whither it is carried from Arabia and the northeastern coast of Africa. Aden in the former region, and Berbera in the latter, would appear, from the statements of Mr. James Vaughan, to be the chief entrepôts of the trade. (*P. J. Tr.*, xii. 226.) Great quantities are collected on the African coast, near the mouth of the Red Sea, whence it is taken to Aden. (*Ibid.*, Oct. 1859, p. 217.) It is usually imported in chests containing between one and two hundred-weight. Sometimes

* According to Prof. Rusby (*Bulletin of Pharmacy*, July, 1892), who has been followed by the revisers of the U. S. P., the name Commiphora antedates the name Balsamodendron some twenty-seven years, having been given by Jacques in 1797.

the different qualities are brought separate, sometimes more or less mingled. Only the best kind should be selected for medical use.*

Properties. Myrrh is in small irregular fragments or tears, or in larger masses, composed apparently of agglutinated portions differing somewhat in their shade of color. The pieces are exceedingly irregular in shape and size, being sometimes not larger than a pea, and sometimes, though rarely, almost as large as the fist. They are often powdery upon the surface. When of good quality, myrrh is reddish yellow or reddish brown and translucent, of a strong, peculiar, somewhat fragrant odor, and a bitter, aromatic taste. It is brittle and pulverizable, presenting when broken a shining surface, which in the larger masses is very irregular, and sometimes exhibits opaque whitish or yellowish veins. In powder it is of a light-yellowish color. Under the teeth it is at first friable, but soon softens and becomes adhesive. It is inflammable, but does not burn vigorously, and is not fusible by heat. Its sp. gr. is stated at 1·36. The inferior kind, commonly called *India myrrh*, is in pieces much darker than those described, more opaque, less odorous, and often abounding with impurities. We have seen pieces of India myrrh enclosing large crystals of common salt, as if the juice had fallen from the tree and concreted upon the ground where this mineral abounds. Pieces of *bdellium*, and other gummy or resinous substances of unknown origin, are often mixed with it. Among these is a product which may be called *false myrrh*. It is in irregular pieces, of a dirty reddish-brown color, a vitreous brownish-yellow fracture, semi-transparent, of a faint odor of myrrh, and a bitter balsamic taste. Myrrh is best purchased in mass, as in powder it is liable to adulterations not easily detected. "When triturated with water, Myrrh yields a brownish-yellow emulsion; with alcohol it yields a brownish-yellow tincture which acquires a purple tint on the addition of nitric acid. Dark-colored pieces, the alcoholic solution of which is not rendered purple by nitric acid, and pieces of gum which dissolve completely, as well as those which merely swell in water, should be rejected." *U. S.*†

Myrrh is partially soluble in water, alcohol, and ether. Triturated with water it forms an opaque yellowish or whitish emulsion, which deposits the larger portion upon standing. Its alcoholic tincture is rendered opaque by the addition of water, but throws down no precipitate. According to Neumann, alcohol and water severally extract the whole of its odor and taste. By distillation a volatile oil rises, having the peculiar flavor of myrrh, and leaving the residue in the retort simply bitter. The gum-resin is soluble in solutions of the alkalies, and, when triturated with them in a crystalline state, forms a tenacious liquid. Hence potassium carbonate may be used to facilitate its suspension in water. Braconnot found 2·5 per cent. of volatile oil, 23 of a bitter resin, 46 of soluble and 12 of insoluble gum. (*Ann. de Chim.*, lxvii. 52.) Pelletier obtained 34 per cent. of resin, with a small proportion of volatile oil, and 66 of gum. A more recent analysis by Ruickoldt gave 2·183 per cent. of volatile oil, 44·760 of resin, 40·818 of gum or arabin, 1·475 of water, and 3·650 of calcium and magnesium carbonate, with some gypsum and ferric oxide. The volatile oil has been called *myrrhol* or *myrrhenol*, and, according to Ruickoldt, has the formula $C_{10}H_{14}O$. Koehler (*A. J. P.*, 1890, p. 346) confirms this formula, and states that this body, while isomeric with thymol and carvol, is distinct from them. He found from 7 to 8 per cent. of essential oil, instead of 2·18 as previously given. Gladstone (*Chem. Soc. Jour.* [2], 2, 1) found that the oil had a sp. gr. of 1·0189 at

* According to G. Schweinfurth, *Mecca Balsam* is yielded by *Commiphora opobalsamum*, from which it is collected in the valleys near Mecca. It is said to be the myrrh of the Bible, the error of translation having been made on account of the similarity of the old Hebrew word "mar" with the modern Arabic word "morr," the name of the true myrrh.

† Four varieties of myrrh are recognized by writers on Materia Medica, but as they do not seem to be clearly distinguishable in the markets, we confine our notice to a foot-note. They are: First. *Somali Myrrh*, which is described in the *Pharmacographia* as follows: "Myrrh consists of irregular roundish masses, varying in size from small grains up to pieces as large as a hen's egg, and occasionally much larger. They are of an opaque reddish-brown color, with a dull, dusty surface. When broken they exhibit a rough or waxy fracture, having a moist and unctuous appearance, especially when pressed, and a rich brown hue. The fractured translucent surface often displays characteristic whitish marks, which the ancients compared to the semicircular mark at the base of the finger-nails. It has a peculiar fragrance and an aromatic, very bitter, and somewhat acrid taste." Second. *Arabian Myrrh of Hanbury*, described in the *Pharmacographia* as "occurring in irregular masses, seldom exceeding 1½ inches long, and having a somewhat gummy-looking exterior. The larger lumps seem formed by the cohesion of small, rounded, translucent, externally shining drops or tears. The fracture is like that of common myrrh, but less unctuous, and has not the whitish markings. The odor and taste are those of the ordinary drug." Third. "*Meetiya*," or *Arabian Myrrh of Dymock*, who states that it is sold in India as true myrrh. This myrrh has a dull surface, a dark reddish-brown color, a more unctuous and waxy fracture, and has white marks like Somali myrrh, which it resembles in taste, but its odor is rather less fragrant. Fourth. *Yemen Myrrh*, which is said by Hanbury to be produced in Yemen, and to contain a resin which differs from that of Somali myrrh and the Arabian myrrh of Hanbury in that its solution in petroleum spirit does not give a violet color on the addition of bromine.

7·5° C., a boiling point of 266° C., and was lævorotatory. The resin, which he calls *myrrhin*, $C_{48}H_{32}O_{10}$, is neutral, but becomes acid when kept for a short time in fusion. In the latter state M. Ruickoldt proposes to call it *myrrhic acid*. (*Archiv der Pharm.*, lxi. 1.) An investigation of the essential oil of *Bisabol* myrrh from the interior of the Somali country has recently been made by W. Tucholka. (*Schimmel's Report*, Oct. 1897, 36.) He obtained 7·8 per cent. of an oil of 0·8836 sp. gr., boiling at from 220°–270° C. From this was separated, by means of the crystalline hydrochloride, a terpene boiling at from 259°–260·2° C., which the author calls *bisabolene*, and an oxygenated portion to which he gives the rather strange formula $C_{56}H_{96}O$. Koehler (*loc. cit.*) finds in the portion soluble in alcohol an indifferent soft resin, to which he gave the formula $C_{26}H_{34}O_5$, containing three replaceable OH groups, and two dibasic resin acids, of the formulas $C_{13}H_{16}O_8$ and $C_{26}H_{32}O_9$. According to MM. Bley and Diesel, myrrh containing little volatile oil always has an acid reaction, which they ascribe to the oxidation of the oil. They found *formic acid* in the specimen examined by them. (*Ibid.*, xliii. 304.) The same writers give as a test of myrrh the production of a transparent dirty-yellow liquid with nitric acid; while false myrrh affords a bright-yellow solution in the same fluid, and bdellium is not dissolved, but becomes whitish and opaque. (*A. J. P.*, xviii. 228.) According to M. Righini, if powdered myrrh, rubbed for 15 minutes with an equal weight of ammonium chloride, and fifteen times its weight of water gradually added, dissolve quickly and entirely, it may be considered pure. (*Journ. de Chim. Méd.*, 1844.) Chas. E. Escott (*A. J. P.*, 1887) extracted a sample of myrrh with petroleum benzin, and on spontaneous evaporation of the solvent obtained 18·75 per cent of oily residue. The gum left after treatment with alcohol had a barely perceptible odor of myrrh and a slightly mucilaginous taste, was neutral to test-paper, and, though of a pale color, gave with water a dark-brown solution. The insoluble portion amounted to 15 per cent., or 8·4 per cent. of the weight of the myrrh. The dilute solution acquired a purple color by ferric chloride, changed to reddish yellow by ammonia. Stronger solutions were precipitated by alcohol, not gelatinized by borax, and the precipitate with lead subacetate was not redissolved. The gum makes a good mucilage, and, when making tincture of myrrh, the residue insoluble in the alcoholic menstruum should be saved for that purpose.

Medical Properties and Uses. Myrrh is a stimulant tonic, with some tendency to the lungs, and perhaps to the uterus. Hence it is employed as a tonic in *dyspepsia*, and as an expectorant and emmenagogue in *debilitated states* of the system, in the absence of febrile excitement or acute inflammation. The complaints in which it is usually administered are *chronic catarrh*, *phthisis pulmonalis*, other *pectoral affections* in which the secretion of mucus is abundant but not easily expectorated, *chlorosis*, *amenorrhœa*, and the various affections connected with this state of the uterine function. It is generally given combined with chalybeates or other tonics, and in *amenorrhœa* very frequently with aloes. It is used also as an application to *spongy gums*, the *aphthous sore mouth* of children, and various kinds of *unhealthy ulcers*. The dose is from ten to thirty grains (0·65–1·95 Gm.), and may be given in the form of powder or pill, or suspended in water, as in the famous antihectic mixture of Dr. Griffith, which has become official under the name of *Mistura Ferri Composita*. The infusion is also sometimes given, and an aqueous extract has been recommended as milder than myrrh in substance. The tincture is used chiefly as a local application.

A *plaster of myrrh* is made by rubbing together powdered myrrh, camphor, and balsam of Peru, of each an ounce and a half, then adding the mixture to 32 ounces of lead plaster previously melted, and stirring well until the plaster thickens on cooling. It is then to be formed into rolls. This plaster may be employed in all cases where a gentle and long-continued rubefacient effect is desired.

NAPHTALINUM. U. S. Naphtalin. [Naphtalene.]

$C_{10}H_8$; 127·7. (NĂPH-TĂ-LĪ'NŬM.)

"A hydrocarbon obtained from coal-tar. It should be kept in well-stoppered bottles." *U. S.*

Naphthaline.

This may be obtained by subjecting coal-tar to distillation, when it passes over in the middle oil and heavy oil; in the fractions of the latter it often constitutes the main constituent, causing it to become almost solid on cooling. It is frequently produced during the dry distillation of organic bodies. For a method of preparing it on a large scale for commercial purposes, see a paper by Vohl, in the *Journ. de Pharm*, 1868, 399; from *Polytech. Journ.*; see also Lunge's *Coal-Tar and Ammonia*, London, 1887. It is made very extensively and cheaply at present

(1899), the sublimed commercial product being nearly pure. It is a white, shining, crystalline substance, fusible at 80° C. (176° F.), and boiling at 217·2° C. (423° F.), but volatilizing with vapor of water. According to Kopp, its sp. gr. in the liquid state is 0·9774; according to Alluard, at 98·8° C. (210° F.), 0·9628. It is soluble in alcohol, chloroform, carbon disulphide, ether, naphtha, and the oils, but insoluble in water. A good test for the purity of naphtalin is to warm a little of it in a test-tube with pure sulphuric acid. As little as one per cent. of impurity will be indicated by its imparting a pinkish tint to the sulphuric acid: the depth of the color indicates the degree of impurity. It is officially described as in "colorless, shining, transparent laminæ, having a strong, characteristic odor resembling that of coal-tar, and a burning, aromatic taste; slowly volatilized on exposure to air. Insoluble in water, but when boiled with the latter imparting to it a faint odor and taste. Soluble in 15 parts of alcohol at 15° C. (59° F.), and very soluble in boiling alcohol; also very soluble in ether, chloroform, carbon disulphide, and fixed or volatile oils. Naphtalin volatilizes slowly at ordinary temperatures; rapidly when heated. It also volatilizes with the vapors of water or alcohol. At 80° C. (176° F.) it melts, and at 218° C. (424·4° F.) it boils. Its vapor is inflammable, burning with a luminous and smoky flame. When ignited, it is consumed, leaving no residue. Naphtalin is neutral to litmus paper moistened with alcohol. On shaking a small portion of Naphtalin with concentrated sulphuric acid, the acid should remain colorless; nor should it acquire more than a pale reddish tint if the mixture be heated for five minutes on a water-bath (absence of *contaminations derived from coal-tar*)." *U. S.*

Medical Properties and Uses. Naphtalin is possessed of antiseptic properties, and is poisonous to most fungi and probably to most insects. Under the name of "*tar camphor*," it has largely supplanted true camphor as a means of preventing the deposition by moths of eggs in woollen clothing, and of preventing the destruction by insects in natural history museums. In internal medicine it was some years ago brought forward by Dupasquier as an expectorant especially valuable in *chronic bronchitis* accompanied with a large amount of secretion. It has also been used with asserted excellent results as a tænicide, and as a vermifuge in cases of seat-worms, when it should be given by injection, from fifteen grains to half a drachm in two to three ounces of olive oil. First employed by Prof. Rossbach, of Jena, in *intestinal catarrh*, it has been largely used in all forms of *intestinal inflammation* and in *typhoid fever*. There seems to be no doubt that in some cases it acts very happily, but the reports concerning it vary, and the remedy is probably inferior to naphtalol. The dose of it is from two to eight grains (0·13–0·52 Gm.), as much as eighty grains being said to have been given in a day without deleterious effects. On the other hand, Dr. J. A. Otte (*Chinese Med. Missionary Journ.*, xi., 1897) violently poisoned himself by eight grains of naphtalin, which was afterwards examined by the chemist and found to be pure. The symptoms were excessive vomiting and purging and great abdominal pain, followed by nephritis. Moreover, employees in gutta-percha works, where it is largely used, are said to be occasionally thrown into a peculiar condition of delirious intoxication. Naphtalin has been used externally as an antiseptic dressing, and also in the treatment of various skin diseases. When given internally, it should always be in the form of powder, and is best administered in capsules.

NAPHTOL. U. S., Br. Naphtol. [Beta-Naphtol.]

$C_{10}H_7OH$; 143·66. (NĂPH'TŎL.)

"A phenol occurring in coal-tar, but usually prepared artificially from naphtalin. Naphtol should be kept in dark amber-colored, well-stoppered bottles." *U. S.* "Beta-naphthol, or beta-mono-hydroxy-naphthalene, $C_{10}H_7OH$, is usually prepared from naphthalene-sulphonic acid." *Br.*

On digesting four parts of naphtalin with three parts of sulphuric acid at 80° C. we have formed *α-* and *β-naphtalin-sulphonic acids*, $C_{10}H_7SO_3H$, which may be separated by means of the barium or lead salts. When heated with sulphuric acid, the *α* acid passes into the *β* variety; therefore the latter acid is exclusively produced at higher temperatures (160° C.). Both of the naphtalin sulphonic acids, when fused with alkaline hydrates, yield the corresponding naphtols, which are designated as *α-* and *β-naphtol*, respectively. The second of these, beta-naphtol, is the official naphtol, $C_{10}H_7OH$. It bears to naphtalin the same relation that phenol (carbolic acid) does to benzene.* It is officially described as "colorless, or pale buff-colored, shining, crystalline laminæ, or a white, or yellowish-white, crystalline

* E. Merck states that the substance known in commerce as *hydronaphtol* is identical with beta-naphtol.

powder, having a faint, phenol-like odor, and a sharp and pungent but not persistent taste. Permanent in the air. Soluble, at 15° C. (59° F.), in about 1000 parts of water, and in 0·75 part of alcohol; in about 75 parts of boiling water, and very soluble in boiling alcohol. Also very soluble in ether, chloroform, or solutions of caustic alkalies. When heated, Naphtol sublimes easily. It is also volatilized with the vapors of alcohol or water. It melts at 122° C. (251·6° F.), and boils at 286° C. (546·8° F.). On ignition, it is consumed, leaving no residue. It is neutral to litmus paper moistened with alcohol. A cold, saturated, aqueous solution of Naphtol, when mixed with ammonia water, exhibits a faint bluish fluorescence. Chlorine or bromine water, added to the aqueous solution, produces a white turbidity, which disappears on adding ammonia water in excess. On adding about 0·1 Gm. of Naphtol to about 5 C.c. of an aqueous solution (1 in 4) of potassium hydrate, then about 1 C.c. of chloroform, and gently warming, the aqueous layer will acquire a blue tint, changing after a while to green and brown. Ferric chloride test-solution colors the aqueous solution of Naphtol greenish, and, after some time, causes the separation of white flakes, which turn brown upon the application of heat. A piece of pine wood dipped into an aqueous solution of Naphtol, and afterwards moistened with diluted hydrochloric acid, becomes green on exposure to daylight. Naphtol should dissolve in 50 parts of ammonia water without leaving a residue (absence of *naphtalin*), and the solution should not have a deeper tint than pale yellow (absence of *various other organic impurities*). If 0·1 Gm. of Naphtol be mixed, in a test-tube, with 1 drop of syrup and 5 C.c. of water, and about 3 C.c. of concentrated sulphuric acid be then poured into the tube held in a slanting position, so that the liquids may form separate layers, a yellowish-brown color will appear at the zone of contact, which becomes darker on standing (absence of, and distinction from, *alpha-naphtol*, which produces at once a crimson color, turning deep blue in the upper part of the zone on standing)." *U. S.* "In white or nearly white crystalline laminæ, or in powder. It has a sharp, pungent taste, and an odor resembling phenol. Soluble in about 1000 parts of cold *water*, in 75 parts of boiling *water*, in less than 2 parts of cold *alcohol* (90 per cent.), and very soluble in boiling *alcohol* (90 per cent.), *ether*, *chloroform*, or *solution of sodium hydroxide*. Melting point 251·6° F. (122° C.). On the addition of 1 drop of *solution of ammonia* to a hot saturated aqueous solution of Beta-naphthol a blue fluorescence is developed. A cold saturated aqueous solution gives a white turbidity with *solution of chlorine*, which, on the addition of excess of *solution of ammonia*, gives place to a green or brown coloration. 0·1 gramme of Beta-naphthol dissolved in 10 cubic centimetres of boiling *water*, and treated with 10 drops of a 3 per cent. aqueous solution of *ferric chloride*, gives a white precipitate becoming brown, but not violet (absence of alpha-naphthol). Beta-naphthol should be neutral to *litmus paper* moistened with *alcohol* (90 per cent.), and should leave no residue on heating to redness (absence of mineral impurities)." *Br.* For Yvon's tests to distinguish between alpha- and beta-naphtol, see *Proc. A. P. A.*, 1892, 955; see also *Chem. News*, 1892, 18. For Liebman's test for presence of alpha-naphtol, see *Merck's Report*, 1897, 281.

The antiseptic and physiological properties of beta-naphtol were first studied by Bouchard and Maximovitch,* who found that the strength of one to three thousand was sufficient to arrest

* *Alpha-Naphtol.* M. Maximovitch has studied alpha-naphtol in the same manner as beta-naphtol. He finds that one part in four thousand is enough to arrest completely the germination of the tubercle-bacillus, that in order to cause death in the rabbit it is necessary to give nine grammes per kilogramme, and that, calculating the toxic dose for man as it was taken for beta-naphtol, it is three times less poisonous than beta-naphtol, and seven hundred times less toxic than mercuric iodide. According to these experiments, alpha-naphtol ought to be superior to beta-naphtol, as being antiseptically much more active, whilst toxically much less active. The dose appears to be the same as that of beta-naphtol. Alpha-naphtol has been proposed as a test for sugar in urine. Posner and Epenstein have studied the action of the test, and consider it to be free from many of the objections raised against other tests for sugar. The test depends upon the fact that a solution of sugar, in the presence of pure concentrated sulphuric acid and a solution of alpha-naphtol, gives a violet-colored reaction, due, according to Udransky, to the separation of furfurol. This reaction occurs not only with sugars, but with all carbohydrates and with certain albuminoids; hence *the urine must be free from albumin*. The test is said to be extremely sensitive, showing *one-hundredth of one per cent.* of sugar. The urine *must always be previously diluted*. *Winckler's test* for hydrochloric acid in the stomach is performed as follows. 5 Gm. of alpha-naphtol are dissolved in 100 C.c. of alcohol, to which is added from 0·5 to 1·0 Gm. of grape sugar. A mixture of the filtered gastric juice is then evaporated with a few drops of the reagent in a porcelain capsule on a water-bath; if free hydrochloric acid be present, a bluish-violet marginal zone will appear and rapidly become inky black.

Various compounds of naphtol have been proposed in medicine. The substance recommended by Polaillon, under the name of *microcidin*, as being ten times more powerful than carbolic acid and less toxic than naphtol, is said to be *sodium naphtol*. (Helbing's *Mod. Mat. Med.*, 79.)

Betol (or *β-naphtyl salicylate*) is specially treated under PART II.

Benzo-naphtol, or *β-naphtyl benzoate*, is a compound of benzoyl and β-naphtol, which in the intestinal tract, theoretically at least, is split up into these constituents. It has been given in doses of from ten to fifteen grains up to ninety grains a day. (See *Benzo-naphtol*, PART II.)

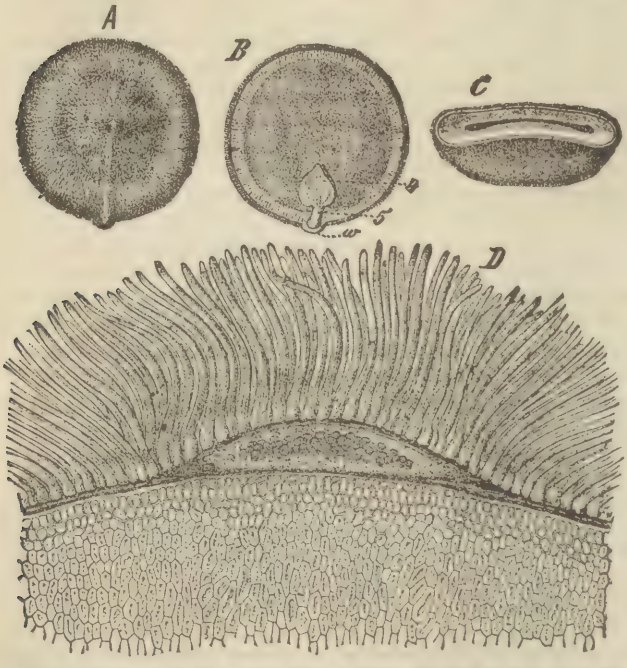
completely the development of some pathogenetic germs in the agar tube, and greatly to retard the development of the bacillus of typhoid fever and of tuberculosis; that the dose of about three grains per quart (0·20 Gm. per liter) was enough to arrest completely the process of putrefaction when in full development. In a careful series of experiments it was found that mercuric iodide is six times more antiseptic than beta-naphtol, but that carbolic acid is five times less antiseptic, and creosote four times less antiseptic. The toxic dose of beta-naphtol was found to be 3·8 Gm. per kilo of the animal, making it two hundred and fifty-three times less poisonous than mercuric iodide. At this rate the poisonous dose for an ordinary man would be between three and four thousand grains. In the animals killed by it, death took place through an arrest of respiration, the heart retaining its activity. As a practical remedy, beta-naphtol was first used in 1881 by Prof. Kaposi, of Vienna, who found that in the dose of one gramme per liter it disinfects and deodorizes urine and fecal discharges, and that applied to the mucous membranes it causes at first a burning sensation and a local irritation, which disappears very rapidly. In solution either in oil or in alcohol it was much more irritating to the skin, one part to one hundred distinctly affecting *eczematous eruptions*, and one to one and a half parts per hundred being sufficient to provoke urticaria on a healthy skin. In the form of soap, containing two parts per hundred, Kaposi found it useful in *prurigo*, *ichthyosis*, *herpes*, and *favus*, obtaining in many cases the best results by alternating this soap with a sulphur soap, and avoiding in this way a cumulation in the system which he believed was possible by the absorption of the drug. The practice of Kaposi was followed by numerous dermatologists with success, and led to the use of the remedy locally in inflammation of the mucous membranes, such as *conjunctivitis*, *chronic laryngitis*, *otitis*, etc.

Prof. Bouchard appears to have been the first to use the drug internally, first, to disinfect pathological cavities; secondly, for intestinal antisepsis, especially in *typhoid fever*. In order to determine whether digestion would not be seriously interfered with by this agent, Mr. Clarke made a series of experiments of its effect upon artificial digestion. He found that hydronaphtol has a very distinct retarding influence on the digestion of egg albumen by peptic fluids, a very slight effect on the digestion of milk by the same, and no effect at all on pancreatic digestion of milk or albumen, nor on the conversion of starch into sugar. The paper of Prof. Bouchard led to the use of beta-naphtol in typhoid fever by a large number of clinicians, and the reports are very strongly in its favor. It is borne well both by adults and by children, rapidly lessening the diarrhœa and other local abdominal symptoms, an amelioration which is said almost invariably to be followed by marked subsidence of the constitutional disturbances. Naphtol has also been used with asserted good results in almost all forms of *diarrhœa* and of *dysentery*. It has also been employed in *dilatation of the stomach*, and in *dyspepsias* of various character, in which, however, the reports of its action are distinctly less favorable. It has even been injected into the trachea by M. Pignol, in *pneumonia*, with asserted good results, from two to three hundred cubic centimetres of a solution of one part per thousand being thrown, drop by drop, during a half-hour, into the trachea by a syringe. Teissier is said to have given it intravenously. It has also been employed, with asserted excellent results, in epidemic *influenza*, and in low fevers with albuminous urine, causing the albumin to disappear. It is a valuable intestinal disinfectant; from three to five grains may be given one hour after meals, in capsules. The same dose of it may be administered every two hours without danger, though the drug is capable of acting as a poison. M. Netter (*Journ. de Clinique et de Thérap. Infantiles*) reports a case in which the injection of a dilute solution containing four grains into the peritoneal cavity for the cure of tubercular disease, produced in a child four years old, in about three-quarters of an hour, violent epileptiform convulsions ending in death. The following formula may be used in the making of the solution: 1. *Weak solution*, for parts in which mucous membranes are exposed: β-naphtol, 5 grammes; alcohol at 60° F., 1 litre. 2. *Ordinary solution:* β-naphtol, 15 grammes; alcohol at 60° F., 1 litre. 3. *Strong solution*, for touching diseased portions of the skin, or septic excoriations: β-naphtol, 15 to 500 grammes per litre. 4. *Solution for interstitial injections, or closed septic cavities:* β-naphtol, 5 grammes; alcohol at 90° F., 33 grammes; hot distilled water, to make 100 cubic centimetres; filter, and use warm. A few drops may be injected into indurated glands or abscesses.

Naphtol-aristol, an odorless, tasteless, greenish-yellow substance, has been used as a local anæsthetic, like iodoform.

Alpha-oxynaphtoic acid is made by the action of carbonic acid gas upon sodium α-naphtol, and bears the same relation to α-naphtol that salicylic acid does to phenol. It has been used as an antiseptic and disinfectant stimulant in skin diseases; also applied as an ointment of 10 per cent.

NUX VOMICA. U. S., Br. Nux Vomica.



(NŬX VŎM'Ĭ-CA.)

"The seed of Strychnos Nux vomica, Linné (nat. ord. Loganiaceæ)." *U. S.* "The dried ripe seeds of Strychnos Nux-vomica, Linn." *Br.*

Semen Strychni, *P. G.;* Semen Nucis Vomicæ; Poison Nut, Quaker Buttons; Noix vomique, *Fr.;* Krähenaugen, Brechnüsse, *G.;* Noce vomica, *It.;* Nuez vomica, *Sp.*

Strychnos nux vomica. L. *Sp. Pl.* (1753) 189; Willd. *Sp. Plant.* i. 1052; *B. & T.* 178. This tree is of a moderate size, with numerous strong branches, covered with a smooth, dark gray bark. The young branches are long, flexuous, smooth, and dark green, with opposite, roundish-oval, entire, smooth, and shining leaves, having three or five ribs, and short footstalks. The flowers are small, white, funnel-shaped, and in terminal corymbs. The fruit is a round berry, about as large as an orange, with a smooth, yellow or orange-colored, hard, fragile rind, and many seeds in a juicy pulp. It has frequently been asserted that the pulp is innocuous; but Flückiger and Hanbury, and also Dunstan and Short (*P. J. Tr.*, xv. 1), have demonstrated that it contains strychnine. Dunstan and Short have also proved that of the commercial varieties of nux vomica Bombay seed stands first, then Cochin, and lastly Madras (*P. J. Tr.*, 1883, 1053) in percentage of contained strychnine.

The tree is a native of the East Indies, growing in Bengal, Malabar, on the Coromandel Coast, in Ceylon, in many islands of the Indian Archipelago, in Cochin-China, and in other neighboring countries. The wood and root are very bitter, and are employed in the East Indies for the cure of intermittents. The *radices colubrinæ* and *lignum colubrinum* of the older writers, long known in Europe as narcotic poisons, have been ascribed to this species of Strychnos, under the impression that it is identical with *Strychnos colubrina*, to which Linnæus refers them. They have been ascertained by Pelletier and Caventou to contain a large quantity of strychnine. The bark is said by Dr. O'Shaughnessy to answer exactly to the description given by authors of the *false Angustura*, and, like that, to contain a large quantity of brucine. The identity of the two barks has been confirmed by Dr. Pereira by a comparison of specimens. (See *Cusparíæ Cortex.*)

Nux Vomica. *A*, seed, natural size; *B*, same, divided, so as to show the embryo; 4, cotyledon; 5, plumule; *w*, radicle; *C*, cross-section; *D*, section through albumen and hilum. (After Berg.)

The seeds are circular, about three-quarters of an inch in diameter, and two lines in thickness, flat or slightly convex on one side, and concave on the other, with a slight ridge extending from the centre of one side to the edge. They are thickly covered with fine, silky, shining, ash-colored or yellowish-gray hairs, springing from, and indeed composed of elongated cells of, a thin fragile coating or testa, which closely invests the interior nucleus or kernel. This is very hard, horny, usually whitish and semi-transparent, sometimes dark-colored and opaque, and very difficult of pulverization. It is composed chiefly of a hard, horny albumen, which on section is seen to be formed of numerous small parenchymatous cells. In a fissure in the centre lies the embryo. It is about a third of an inch long, with a club-shaped radicle and two cordate, five- to seven-nerved cotyledons. The powder is yellowish gray, and has a faint sweetish odor. The seeds are destitute of odor, but have an acrid, very bitter taste, which is much stronger in the kernel than in the

investing membrane. They impart their virtues to water, but more readily to diluted alcohol. For a method of distinguishing powdered nux vomica from powdered ignatia and other powders, see *Proc. A. P. A.*, 1897, 503.

Pelletier and Caventou discovered in nux vomica two alkaline principles, *strychnine* and *brucine*, united with a peculiar acid which they named *igasuric*. Its other constituents are a yellow coloring matter, a concrete oil, gum, starch, a small quantity of wax, and several earthy phosphates. Mr. Charles Bullock, in preparing the alcoholic extract of nux vomica with a moderate continuous heat, so as to dry it sufficiently to be pulverized, separated from 150 pounds of the seeds 5 pints of a liquid oil. (*A. J. P.*, 1874, 405.)* Shenstone (*Journ. Chem. Soc.*, xxxix. 453) has shown that the *igasurine* of M. Desnoix is a mixture of strychnine and brucine. A glucoside, *loganin*, has also been found in the nux vomica seeds, but it exists more largely in the surrounding pulp. Dunstan and Short, its discoverers (*Pharm. Journ.* [3], xiv. 1025), give to it the formula $C_{25}H_{34}O_{14}$.†

Transverse section of Nux Vomica.

Strychnine ($C_{21}H_{22}N_2O_2$) was discovered by Pelletier and Caventou in 1818, in both the nux vomica and the bean of St. Ignatius, and received its name from the generic title of the plants (*Strychnos*) to which these two products belong. According to these chemists, it exists much more abundantly in the bean of St. Ignatius than in the nux vomica, the former yielding 1·2 per cent., the latter only 0·4 per cent., of the alkaloid; but Dragendorff obtained from the nux vomica from 1·9 to 2·1 per cent. of mixed alkaloids, about half of which was strychnine. (*Jahresbericht*, 1874, 103.) ‡ For valuable practical information about the yield of the alkaloids, extracts, etc., by Prof. E. L. Patch, see *Proc. A. P. A.*, 1891, 91; also *P. J. Tr.*, 1889, 341; *Proc. Michigan Pharm. Assoc.*, 1889; *Proc. Ohio Pharm. Assoc.*, 1889; *P. J. Tr.*, 1890, 493.

Brucine ($C_{23}H_{26}N_2O_4$) was discovered by Pelletier and Caventou, first in the bark called *false Angustura*, in combination with gallic acid, and subsequently, associated with strychnine in the form of igasurates, in the nux vomica and the bean of St. Ignatius. It is crystallizable from alcohol, the crystals then containing $4H_2O$. It is without smell, but of a permanent, harsh,

* F. Meyer (*Dissertation*, St. Petersburg, 1875) investigated the fatty oil from nux vomica, and found it to consist of the glycerides of capric, caprylic, caproic, butyric, and palmitic acids.

† *Loganin* is present in the pulp to the amount of 4 or 5 per cent., and is contained in small quantity also in the seeds. It was obtained by exhausting the pulp with a mixture of chloroform and alcohol (100 : 25). The exhaustion was effected in an apparatus for hot repercolation. The percolate, on cooling, deposited crystals, which when recrystallized a number of times from alcohol, and finally from absolute alcohol, were obtained pure. Loganin is easily soluble in water and alcohol, less soluble in ether, chloroform, and benzene. Its aqueous solution is not precipitated by any of the alkaloidal reagents. Its most characteristic reaction is found in its behavior with concentrated sulphuric acid. A very small quantity of loganin, when gently warmed with a few drops of concentrated sulphuric acid, yields a fine red color, which, on standing, develops into a deep purple. By boiling with dilute sulphuric acid, loganin is resolved into glucose (reducing Fehling's solution), and a body for which the name *loganetin* is proposed. This substance, like loganin, gives the characteristic reaction with sulphuric acid, but the purple color does not develop so rapidly. Loganetin is soluble in water and alcohol, less soluble in ether and chloroform. (*P. J. Tr.*, 1884, p. 1025.)

‡ Other species of Strychnos contain the poisonous alkaloids, and may some time become a commercial source of them. *Bidara laut* of the Indian bazaars, believed to be obtained from *S. ligustrina*, has been analyzed by Prof. Russow, who found the wood to contain 2·26 per cent. and the bark 7·38 per cent. of brucine without strychnine. Mr. Henry G. Greenish found in the wood and bark respectively of *S. colubrinum* 0·96 per cent. and 5·54 per cent. of mixed alkaloids; the same analyst obtained from false Angustura bark (*S. nux vomica*), young bark 3·10 per cent., old bark 1·68. (*P. J. Tr.*, 3d ser., ix. 1014.) According to M. Bernelot-Moens, the dry seeds of the *S. tieute* contain 1·469 per cent. of strychnine, with a trace of brucine. (*A. J. P.*, 1866, p. 506.)

very bitter taste; is soluble in 850 parts of cold and in 500 of boiling water; very soluble in alcohol, whether hot or cold; it dissolves in 4 parts of chloroform, 440 parts of ether, 60 parts of benzene, and 120 parts of benzin. It is permanent in the air, but melts at a temperature a little above that of boiling water, and on cooling congeals into a mass resembling wax. The hydrated crystals melt at 115° C. (239° F.), and sublime at 204° C. (399·2° F.), while the anhydrous base melts at 178° C. (352·4° F.), changing color, and depositing carbon. (*P. J. Tr.*, 1868, 375.) It forms crystallizable salts with acids. Concentrated nitric acid produces with brucine or its salts an intense crimson color, which changes to yellow by heat, and upon the addition of stannous chloride becomes violet. A test for brucine, given by M. Stanislas Cotton, consists in adding to a warm solution of brucine (from 40° to 50° C.) in nitric acid, a concentrated solution of sodium hyposulphite (thiosulphate). The mixture first becomes violet, and then passes to green when the alkaline salt is in excess. (*Journ. de Pharm.*, Juillet, 1869, 18.) These effects serve to distinguish brucine from strychnine, and, if produced with the latter alkaloid, evince the presence of the former. According to MM. Larocque and Thibierge, auric chloride produces, with solutions of the salts of brucine, precipitates at first milky, then coffee-colored, and finally chocolate-brown. (*Journ. de Chim. Méd.*, Oct. 1842.) Chlorine water produces with solution of brucine a rose color, due to the formation of *dichlor-brucine*. This is a reddish-brown, hygroscopic powder. (*Archiv d. Pharm.*, 1886, 934.) A *dinitro-brucine*, $C_{23}H_{24}(NO_2)_2N_2O_4$, has also been obtained by the action of nitrogen trioxide upon the brucine in alcoholic solution. Brucine appears to bear a definite relation to strychnine in chemical constitution, being a *dimethoxy-strychnine*. According to the analyses of Shenstone and Dragendorff, the bark of the nux vomica contains brucine, with a trace of strychnine, whilst in the leaves Hooper found only brucine. (*P. J. Tr.*, xxi.)

This alkaloid has been detected in the body three months after death, being present in all the solids and fluids, but especially in the liver and kidneys. (*Boston Med. and Surg. Journ.*, July 10, 1873, p. 36.) Brucine may be procured from false Angustura bark, in a manner essentially the same as that in which strychnine is procured from nux vomica; with this difference, that the alcoholic extract obtained from the precipitate produced by lime or magnesia should be treated with oxalic acid, and subsequently with a mixture of rectified alcohol and ether, which takes up the coloring matter, leaving brucine oxalate. This is decomposed by magnesia, and the brucine is separated by alcohol, which by spontaneous evaporation yields it in the state of crystals. Prescott (*Organic Analysis*, 1887, p. 458) gives two methods for the separation of strychnine from brucine: first, by the use of alcohol of 0·97 sp. gr., which easily dissolves brucine, but has very slight solvent power upon strychnine; second, by Dunstan and Short's method with potassium ferrocyanide. This has recently been reported upon by Holst and Beckurts (*Pharm. Centralhalle*, N. F., 1887, p. 119), who find that if the mixed alkaloids be in not too dilute hydrochloric acid solution, on the addition of potassium ferrocyanide the whole of the strychnine will be precipitated as ferrocyanide, while the brucine salt will remain in solution.

Igasurine was said to be found in the mother-waters from which strychnine and brucine have been precipitated by lime. Jörgensen believed that it was identical with brucine (see *A. J. P.*, June, 1872, p. 257), and W. A. Shenstone confirmed this view. (*A. J. P.*, Dec. 1881.) Recent investigations show, however, that its existence is very doubtful.

Igasuric acid has been regarded as erroneously named, and investigators have stated that it was malic acid and tannic acid, whilst G. Sander (*Archiv d. Pharm.* 1897, 133) believes that the acid found in nux vomica, heretofore known as igasuric acid, is *caffeo-tannic acid*.

As a test for nux vomica, Vielgruth proposes to treat a few grains of the suspected powder with proof spirit, evaporate the tincture to dryness at a heat not exceeding 96° F., then add a drop or two of dilute sulphuric acid, and again raise to the heat mentioned. If nux vomica be present, a beautiful carmine-red color will be produced, which will disappear in ten or fifteen minutes after cooling, and reappear, but less brightly, on the reapplication of the heat. Schweissinger advocates the direct determination of the alkaloids in nux vomica by titration with hydrochloric acid as the best way of ascertaining the strength of pharmaceutical preparations. (*Archiv d. Pharm.*, 1885, 579.) Keller's method of estimating the alkaloids in nux vomica (see *Proc. A. P. A.*, 1895, 1024) is commended by Sander. (*Archiv d. Pharm.*, 1897, 133; see also *A. J. P.*, 1896, 189.)

Brucine. On account of the difficulty of separating strychnine from brucine, it has been found by physiologists difficult to determine the exact action upon the human organism of the pure alkaloid. It would seem, however, from the studies of Prof. Reichert, made upon

carefully tested brucine, that its physiological actions are similar to those of strychnine, except that it is much less rapidly absorbed than is strychnine, is from forty to fifty times less powerful as a convulsant, is more poisonous to the sensory nerves, and is more uncertain in its effects upon bodily temperature. When brucine is brought in contact with the nerves of the frog it produces a rapid paralysis of the sensory fibres. Dr. Mays found that a five- or ten-per-cent. solution of chemically pure brucine applied to the mouth of man causes rapid loss of sensibility, and asserts that a twenty-per-cent. solution is capable of exerting a decided local anæsthetic influence when placed upon the skin. He has found it very advantageous for the relief of the itching of *chronic pruritus*. Drs. Zeiss and Burnett find that a five-per-cent. solution gives great relief as a local application in inflammations about the external ear, Dr. Burnett affirming that his results have been far more satisfactory than those which he has obtained with cocaine.

Medical Properties and Uses. The medical and toxic properties of nux vomica are those of its alkaloid. (See *Strychnina*.) The belief held by some physicians that it acts more favorably as a bitter upon the stomach has only this much of justification,—namely, that it is more slowly absorbed, and therefore acts locally somewhat more persistently.

OLEA. Oils.

(Ō'LĒ-A.)

These are liquid or solid substances, unctuous to the touch and characterized by inflammability and the property of making a greasy stain upon paper. They are divided into two classes, the *fixed* and the *volatile*, because distinguished, as their names imply, most readily by their different behavior on the application of heat.

1. OLEA FIXA. *Fixed Oils.*

These are sometimes termed *fatty oils*, because they constitute in part the vegetable and animal fats. The distinction between liquid and solid fats is for the most part a physical one only, as they contain the same chemical compounds, although in relatively different proportions. The fatty oils, though existing in greater or less proportion in various parts of plants, are furnished for use exclusively by the fruit, and, as a rule, are most abundant in the dicotyledonous seeds. They are obtained either by submitting the bruised seeds to pressure in hempen bags, or by boiling them in water, and skimming off the oil as it rises to the surface. When pressure is employed, it is customary to prepare the seeds for the press by exposing them to a moderate heat, so as to render the oil more liquid and thus enable it to flow out more readily. Another mode of extracting certain oils is by means of liquids having the power of dissolving them, and this method is now largely used in practice, carbon disulphide being the solvent availed of. Near Berlin, in Germany, is an establishment where the oil existing in various grains, as the colza, flaxseed, and mustard, is extracted by means of carbon disulphide, on a large scale. For the details of the process, see *A. J. P.*, Nov. 1868, 549. Fixed oils may be clarified by subsidence, filtration through animal charcoal or porous solids, precipitation with tannin, lead acetate, plaster of Paris, albumen, gelatin, or other agents; cellulose and asbestos filters are often used; and on the large scale, for separating mechanical impurities, centrifugal machines like those employed for milk.

The following scheme of classification of the fixed oils, both liquid and solid (Allen, *Commercial Organic Analysis*, 2d ed., vol. ii. pp. 62–73), gives a general view of their most essential characters, points of difference, etc.

I. Olive Oil Group. *Vegetable Non-drying Oils.* The oils of this group solidify on treatment with nitrous acid or mercuric nitrate, but do not lose their power of producing a greasy stain on paper, however long they may be exposed to the air. Their density varies from 0·912 to about 0·920, and hence is less than that of Groups II., III., and IV. Their fluidity is notably less than that of the drying oils.

This group includes almond oil (from *Amygdalus communis*), oil of ben (from *Moringa oleifera*), colza oil (from *Brassica campestris oleifera*), ground-nut oil (from *Arachis hypogæa*), oil of black mustard (from *Sinapis nigra*), oil of white mustard (from *Sinapis alba*), olive oil (from *Olea europæa*), winter rape-seed oil (from *Brassica campestris; B. napus*), and summer rape-seed oil (from *Brassica præcox*).

II. Cotton-seed Oil Group. The oils of this group occupy a position intermediate between the vegetable non-drying and the true drying oils (Groups I. and III.). In density they

somewhat exceed the oils of Group I., but are lighter than those of Groups III. and IV. They form more or less elaidin on treatment with nitrous acid or mercuric nitrate, but do not become wholly solidified. On the other hand, they undergo more or less drying on exposure to the air, but not so markedly as the oils of Group III.

This group includes beech-nut oil (from *Fagus sylvatica*), cotton-seed oil (from *Gossypium barbadense* and other species), hazel-nut oil (from *Corylus avellana*, see *Proc. A. P. A.*, 1893), sesame or teel oil (from *Sesamum orientale*), sunflower oil (from *Helianthus annuus; H. perennis*), and niger-seed oil (from *Guizotia oleifera*).

III. Linseed Oil Group. *Vegetable Drying Oils.* These oils are not solidified by treatment with nitrous acid or mercuric nitrate, but become gradually converted into solid masses or varnishes, by exposure to the air. In density the oils of this group vary from about 0·923 to 0·937, and hence are distinctly heavier than the non-drying oils and than most of the oils of Group II. On the other hand, they are lighter than the oils of Group IV. The fluidity of the drying oils is also much higher than that of the non-drying oils.

This group includes camelina oil (from *Myagrum sativum*), cress-seed oil (from *Lepidium sativum*), hemp-seed oil (from *Cannabis sativa*), linseed oil (from *Linum usitatissimum; L. perenne*), poppy-seed oil (from *Papaver somniferum*), Scotch fir-seed oil (from *Pinus sylvestris*), tobacco-seed oil (from *Nicotiana tabacum*), walnut oil (from *Juglans regia*), and weld-seed oil (from *Reseda luteola*).

IV. Castor Oil Group. The oils of this group are distinguished from those of Groups I., II., and III. by their very high density and viscosity (*i.e.*, deficient fluidity). They are also remarkable for their ready solubility in alcohol, and their marked purgative properties. In their drying characters and behavior with the elaidin test they resemble the oils of the cotton-seed oil group. Both castor and croton oil are miscible in all proportions with glacial acetic acid.

This group includes castor oil (from *Ricinus communis*) and croton oil (from *Croton tiglium*).

V. Palm Oil Group. *Solid Vegetable Fats.* This group includes solid fats not containing notable quantities of glycerides of lower fatty acids. The densities for the melted fats at 98° and 99° C. are compared with the density of water at 15·5° C., taken as 1·000, and vary from 0·920 to 0·995, calculated at 15·5° C. This group includes palm oil (from fruit of *Elais guineensis*), cacao butter (from nuts of *Theobroma cacao*), nutmeg butter (from nuts of *Myristica fragrans*), and shea butter (from seeds of *Bassia parkii*).

VI. Cocoanut Oil Group. *Solid Vegetable Fats.* This group includes solid fats containing notable quantities of glycerides of lower fatty acids,—that is, of acids distilling with more or less facility in a current of steam at 100° C. The group includes cocoanut oil (from nuts of *Cocos nucifera*), palm-nut oil (from kernels of nut of *Avoira elais* or *Elais guineensis*), and laurel oil (from fruit of *Laurus nobilis*).

VII. Lard Oil Group. *Animal Oleins.* This group includes those oils fluid at ordinary temperatures which are obtained from terrestrial animals. They resemble the fish oils in their reaction with chlorine, but are not turned red or brown by boiling with caustic soda. On exposure to air and on treatment with nitrous acid or mercuric nitrate, they behave like the non-drying vegetable oils (Group I.).

This group includes bone oil, lard oil, tallow oil, and neat's-foot oil.

VIII. Tallow Group. *Solid Animal Fats.* This group comprises such oils as are solid at the ordinary temperature. Their melting points vary somewhat, and are capable of permanent alteration. The group includes bone fat, butter fat, butterine and oleomargarine, hog's lard, horse fat, beef tallow and mutton tallow, and wool-fat (suint).

IX. Whale Oil Group. *Marine Animal Oils.* This group comprises the various fluid oils obtained from fish and cetaceous mammals. They are distinguished as a class by their offensive fishy odor, by the brown color they assume when subjected to the action of chlorine, and by the reddish color which is produced on boiling them with a solution of caustic alkali. With sulphuric acid they give colorations varying from light red to purple or brown. Sperm oil is distinguished from the others by its peculiar chemical constitution and low specific gravity. The fish oils do not dry up on exposure to air, and mostly yield but little elaidin on treatment with nitrous acid. The term "*train oil*" includes whale, seal, shark, cod, and all similar oils. Cod oil (from *Gadus morrhua* and allied species), cod-liver oil (from the same), tanner's cod oil (from various fish), menhaden oil (from *Alosa menhaden*), porpoise oil (from *Delphinus phocæna* and allied species), seal oil (from *Phoca* of various species), shark oil (from *Squalus maximus* and allied species), sperm oil (from the cranial cavities of *Physeter macrocephalus*),

and whale oil (from *Balæna mistecetus* and allied species), are all members of this group. For a description of various animal oils, see *Bull. Pharm.*, 1893, 297.

X. Sperm Oil Group. *Liquid Waxes.* The members of this group differ from all the fatty oils of previous classes in not being glycerides, consisting essentially of ethers of monatomic alcohols of the ethylic series, in which respect they resemble the true waxes, but are fluid at ordinary temperatures. They are less dense than the glycerides, they do not dry or thicken notably on exposure to air, but they yield solid elaidins on treatment with nitrous acid. The group includes sperm oil, doegling oil or bottle-nose oil, and dolphin oil.

XI. Spermaceti Group. *Waxes Proper.* Spermaceti and the various waxes differ from the true fixed oils and fats in not forming glycerin when saponified, yielding instead certain of the higher monatomic alcohols, the identity of which varies with the nature of the wax. These alcohols are insoluble in water, and dissolve to but a limited extent in alcohol, but they are soluble in ether, chloroform, carbon disulphide, benzene, and petroleum spirit, and are apt to be mistaken for added paraffin wax when the substance is saponified and the soap extracted with a solvent.

This group includes beeswax (from honey-comb of various species of bees), Carnauba or Brazil wax (from the leaf-coverings of *Copernicus cerifera*), Chinese wax or Pela wax (produced by a species of *Coccus* which punctures the branches of certain trees), myrtle wax (from berries of *Myrica cerifera*), Ocuba wax (from *Myrica ocuba*), palm wax (from bark of *Ceroxylon andicola* of the Cordilleras), and spermaceti (deposit from the oil found in the cranial cavities of the sperm whale, *Physeter macrocephalus*).

When oils are decomposed by heat they emit vapors of *acrolein*, a highly volatile liquid resulting from the decomposition of glycerin, upon which the fumes of oils mainly depend for their irritating effects on the eyes and nostrils. Exposed to a red heat, in closed vessels, they yield, among other products of the destructive distillation, a large quantity of combustible and illuminating gases, among which ethylene and acetylene are readily recognized. Heated in the open air, they take fire, burning with a bright flame, and producing water and carbonic acid. When kept in air-tight vessels, they remain unchanged for a great length of time; but exposed to the atmosphere they attract oxygen and undergo change. Some, in drying, lose their unctuous character, and are converted into a transparent, yellowish, flexible solid. These are called *drying oils.* Others, especially such as contain mucilaginous impurities, become rancid, acquiring a sharp taste and an unpleasant smell. This change is owing to the formation of an acid, from which the oil may be freed by boiling it for a short time with magnesium hydrate and water.* The fixed oils are insoluble in water, but are miscible with that fluid by means of mucilage, forming mixtures which are called emulsions. They are in general very sparingly soluble in alcohol, but readily dissolved by ether, which serves to separate them from other vegetable proximate principles. By the aid of heat they can dissolve sulphur and phosphorus. The stronger acids decompose them, giving rise, among other products, to oleic, palmitic, and stearic acids. Boiled with diluted nitric acid, some of them give rise to malic and oxalic acids, besides other substances usually resulting from the action of this acid upon vegetable matter. Several acids are dissolved by them without producing any sensible change. They are decomposed by salifiable bases, which set free glycerin and oleic, stearic, or other fatty acids, which acids unite with the base employed. The compounds of these acids with potassa and soda are called soaps. (See *Sapo* and *Emplastrum Plumbi.*) By the addition of one part of potassium or sodium carbonate, 160 parts of oil may be brought with distilled water into the form of an emulsion. The potassa and soda soaps and the alkaline sulphides have a similar effect, but not the bicarbonates. The fixed oils also serve as good vehicles for various metallic bases and subsalts, which form soaps to a certain extent soluble in the oil, and thus become less irritant to the tissues. Oils thus impregnated may, like the pure oils, be

* M. Cloes has made investigations in relation to the influence of light in promoting oxidation, and obtained some curious results. The general influence of light is very great, as oils undergo comparatively little change in the dark for a long time; though in relation to some of them the change is at length as great as under the light. Thus, while the oil of poppies has in 30 days increased about 5 per cent. in weight under colorless light, and has gained only a 5000th in the dark, yet at the end of 150 days the weight in the former condition was rather lessened than augmented, and in the latter, or in the dark, had increased 6·4 per cent. The effect of the different colored rays is also very different. The change is at first most rapid under the white light, less so under the blue, and much less under the red, yellow, and green, being least of all with the green; but with the advance of time the blue overtakes and even passes the white, and at the end of three or four months all are about equal in effect. Heat also accelerates the concretion of the oils, by favoring their oxidation; and the same effect is produced by introducing into the unchanged oil a little which has already been altered by exposure to the air. The oxidation of an oil may be very greatly hastened in this way without the aid of heat. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 345, 1865.)

brought to the state of emulsion with water, for convenient administration, by the addition of a small proportion of potassium carbonate. (Jeannel and Monsel, *Revue Pharm.*, 1857, p. 48.) The fixed oils dissolve many of the alkaloids, the volatile oils, resin, and other proximate principles of plants. The alkaloids are more readily dissolved in them by being first combined with oleic acid, the oleates being more soluble than the alkaloids themselves. (Attfield, *P. J. Tr.*, March, 1863, p. 308.) According to Buignet, they are, with very few exceptions, indifferent to polarized light; of all those used in medicine, the only exceptions being the liver-oils of the ray and dog-fish, which have a very feeble left-rotatory power, and castor oil, which is decidedly dextrogyrate. (*Journ. de Pharm.*, Oct. 1861, p. 264.)

The fixed oils, whether animal or vegetable, in their natural state consist in most cases of at least two or three distinct oleaginous ingredients, one liquid at ordinary temperatures, and the other two concrete. The liquid is a distinct proximate principle, called *olein;* the concrete principles consist of *stearin* and *palmitin*, the former being found most largely in animal and the latter in vegetable oils or fats, and the two in most cases existing together in the same oil. As the most frequent of these proximate constituents of the fixed oils, and existing in many different oleaginous substances, olein, palmitin, and stearin merit a special notice. Preliminarily, however, to their individual consideration, it will be proper to refer to the existing views in relation to their nature and composition generally.

These three substances, *olein*, *palmitin*, and *stearin*, together with *butyrin*, *caprin*, and other minor fat principles, are *glycerides;* that is, compound ethers or salts of the triatomic alcohol glycerin, $C_3H_5(OH)_3$, and of the several fatty acids, oleic, palmitic, stearic, etc., all of which are monobasic acids. Thus, olein has the composition

$$C_3H_5\begin{cases}OC_{18}H_{33}O\\OC_{18}H_{33}O\\OC_{18}H_{33}O\end{cases}$$, palmitin, $$C_3H_5\begin{cases}OC_{16}H_{31}O\\OC_{16}H_{31}O\\OC_{16}H_{31}O\end{cases}$$, and stearin, $$C_3H_5\begin{cases}OC_{18}H_{35}O\\OC_{18}H_{35}O\\OC_{18}H_{35}O\end{cases}$$.

When these substances, or oils composed principally of them, are treated with alkali with the aid of heat, the following decomposition takes place:

$$C_3H_5\begin{cases}OC_{18}H_{33}O\\OC_{18}H_{33}O\\OC_{18}H_{33}O\end{cases} + 3(NaOH) = C_3H_5\begin{cases}OH\\OH\\OH\end{cases} + 3(Na.OC_{18}H_{33}O);$$

that is, olein is decomposed by sodium hydrate into *glyceryl hydrate*, or *glycerin* and *sodium oleate*, or a sodium soap.

The waxes differ from the fats proper in being compound ethers of the higher monatomic alcohols, like *cetyl alcohol*, $C_{16}H_{33}.OH$, and *myricyl alcohol*, $C_{30}H_{61}.OH$, instead of being glycerides. The fatty acids present are partly palmitic and stearic, but more largely still higher ones, like *cerotic acid*, $C_{27}H_{54}O_2$.

Olein. Elain. Liquid Principle of Oils. It is extremely difficult to obtain olein pure. Being in most oils associated with the solids stearin and palmitin, it has to be separated by pressure and other mechanical means, which separation is not always perfectly effected. As ordinarily procured, therefore, olein contains more or less of palmitin or stearin, or both. In this somewhat impure state it is obtained either by the agency of alcohol or by expression. When one of the oils, olive oil, for example, is dissolved in boiling alcohol, the solution, on cooling, deposits the concrete principles, still retaining the olein, which it yields upon evaporation. The other method consists in compressing one of the solid fats, or one of the liquid oils rendered concrete by cold, between folds of bibulous paper, which absorb the olein, and give it up afterwards by compression under water. Olein is a liquid of oily consistence, congealing at —6° C. (21·2° F.), colorless when pure, with little odor and a sweetish taste, insoluble in water, soluble in boiling alcohol and ether. Its formula, as already stated, is $C_3H_5(OC_{18}H_{33}O)_3$, being an oleate of the triad radical *glyceryl*, C_3H_5. By reaction with nitric acid, or, more exactly stated, under the influence of nitrous acid fumes, olein is converted into a deep yellow, butyraceous mass. If this be treated with hot alcohol, a deep orange-red oil is dissolved, and a peculiar fatty matter remains, called *elaidin*. This is white, crystalline, fusible at 34° C. (93·2° F.), insoluble in water, readily soluble in ether, and appears to be isomeric with olein. It is resolved by saponification with the alkalies into *elaidic acid* and glycerin.

Palmitin. Palmitic acid occurs in the more liquid fats, such as palm oil and cocoa-nut oil, as well as in butter and human fat, as glyceride; while in spermaceti and some forms of wax it is combined with monatomic alcohol radicals. Palmitin is the *palmitic acid glyceride*, or *glyceryl tripalmitate.* It is best obtained from palm oil.

Stearin. This exists abundantly in tallow and other animal fats. It may be obtained by

treating the concrete matter of lard, free from olein, by cold ether so long as anything is dissolved. The palmitin is thus taken up, and stearin remains. A better method is to dissolve suet in heated oil of turpentine, allow the solution to cool, submit the solid matter to expression in unsized paper, repeat the treatment several times, and finally dissolve in hot ether, which deposits the stearin on cooling. This is concrete, white, opaque in mass, but of a pearly appearance as crystallized from ether, pulverizable, fusible at 66·5° C. (152° F.), soluble in boiling alcohol and ether, but nearly insoluble in those liquids cold, and quite insoluble in water. It consists of glyceryl and stearic acid in combination as a glyceride, $C_3H_5(OC_{18}H_{35}O)_3$, and has been formed synthetically by heating a mixture of these two materials to 280°–300° C.

Margarin. What was long known under this name was stated by Heintz in 1852 (*Journ. für Prakt. Chem.*, 56, p. 1) to be a mixture of stearin and palmitin: this view has been contradicted recently, however, and some chemists recognize the identity of margarin as one of the simple constituents of fats. The true *margaric acid* was believed to have been obtained only by synthesis, not occurring in nature.

The fixed oils are liable to certain spontaneous changes, which have been investigated by MM. Pelouze and Boudet. It appears from their researches that the oils are accompanied, in the seeds which contain them, with principles which act as a ferment and cause the oils to resolve themselves spontaneously into the several fatty acids which they afford on saponification, and into glycerin. This change takes place in the seeds as soon as the cells containing the oil are broken, so as to permit the contact of the fermenting principle existing in the grain. Sometimes the fermenting principle is to a certain extent separated from the seeds along with the oil. In such a case the oil undergoes this resolution into the fatty acids and glycerin after expression. Such was ascertained to be the case with palm oil, in which, after long keeping, MM. Pelouze and Boudet detected the presence of glycerin and of palmitic and oleic acids. They moreover proved that, under the continued influence of the ferment, the fatty acids themselves undergo changes, among which is the conversion of the oleic into sebacic acid; and it is probable that with a still longer continuance of the same influence the oil would be completely destroyed. As this rancidity in fats renders them altogether useless in pharmacy, and as it is not always readily discoverable by the senses in its earlier stages, it becomes desirable to possess a test by which it may be readily detected. Such a test is to be found, according to Mr. Thos. B. Groves, in potassium iodide, which is rapidly decomposed by the new principles developed, and, by the orange-brown discoloration produced by the liberation of the iodine, indicates the existence of rancidity, and by the rapidity and degree of that discoloration, approximatively, the extent of the change. The alteration of color is said by Mr. Groves to be plainly perceptible when only one-twentieth of rancid fat is present. The presence of water in a fatty oil favors the production of rancidity.

It is also extremely important to be able to protect fats against this change. The complete exclusion of air, light, and moisture—and, when in relation to air this may not be entirely practicable, the destruction by heat of the ferment-germs contained in the air, by which the decomposition is often originated—will go far to effect this object; but it would often be very inconvenient, if not impossible, to carry these measures into complete effect; and hence the discovery of substances which may have the effect of retarding, if not wholly preventing, these fermenting processes, whether by the destruction of the ferment-germs or otherwise, is extremely desirable. It is now long since one or more substances having this preservative effect have been made known and practically used; and since the principle upon which they are supposed to act has been discovered the number has been much extended. Thus, benzoin rubbed up with fats is well known to preserve them long against rancidity, and *benzoinated lard*, made by mixing ten per cent. of benzoin with melted lard, is one of the official preparations; and the buds of the poplar (*Populus nigra*) are perhaps still more effectual, as, according to M. Deschamps, lard impregnated with their virtues will keep good indefinitely. In the French Codex the poplar buds are employed for this purpose in the *Pommade Populeum*, in which eight parts of the dried buds are used to 60 parts of the ointment, consisting of lard impregnated with the virtues of several narcotic substances, the fresh narcotic plants being boiled with lard until all their water is evaporated, and the buds afterwards digested in the strained liquid for 24 hours. Mr. Groves made experiments with many volatile oils and other analogous substances to test their preservative power; and, while many of them were found to have considerable effect, as cloves, Peruvian balsam, sassafras, guaiacum, and creosote, yet the one which appeared to act most efficiently was the *oil of pimenta;* and he proposes to add to the official *prepared lard* of the British Pharmacopœia either oil of pimenta or balsam of Peru, in the

proportion of two drops to the ounce, in order to contribute to its preservation. (See *A. J. P.*, 1865, 54, 61.)

Animal fats are especially liable to become rancid when kept; and it is very desirable to obviate this effect; for, instead of having the mild demulcent properties which constitute their chief value, they become irritant, and unfit as vehicles for other substances to be applied to the skin. Prof. Hirzel says that animal fats may be kept in a good condition for a year by the following plan. Mix 14 pounds of the recently melted fat with 5 drachms of common salt and 15 grains of alum, in fine powder, heat till a scum is formed on the surface, separate the scum, and, when the clear liquid has cooled, wash it many times with water with malaxation, so as to remove all the salt, then evaporate the water at a heat insufficient to injure the fat. (*A. J. P.*, 1868, 334.)

The adulteration of the fixed oils may be effected in two ways,—by admixture with the fatty oil of substances distinctly foreign to the fats, and by adding a cheaper or inferior oil to one of greater value. In the former case we may have the addition of paraffin wax, ceresine, mineral oils, neutral tar oils, resin oils, resin, and waxes. Of these, the first three are entirely unsaponifiable, resin oils contain but small quantities of saponifiable substances, waxes are partly saponifiable, and resin almost completely saponifiable. The determination of unsaponifiable matter is therefore of great importance. The common method for this is to saponify the suspected sample with alcoholic potash and then to shake out the unsaponifiable matter with ether or petroleum ether. From this solution, on evaporation, will be obtained the mineral resin or tar oils that may have been present. For these there are appropriate tests elsewhere noted. In case a cheaper oil or fat has been added for the purpose of adulterating a more valuable one, we must be guided by the determination of certain constants, such as those mentioned below by Cowley, or by the indication of certain qualitative color tests. The constants referred to are much more to be depended upon in such a case.

R. C. Cowley (*P. J. Tr.*, 1897, 331) regards the following as the most important determinations in examining fats and fixed oils. 1. Specific gravity. 2. Melting and solidifying points. 3. Melting and solidifying points of fatty acids. 4. Behavior with solvents. 5. The Hehner value. 6. The Reichert-Meissl value. 7. The saponification value. 8. The iodine value.

It is sometimes desirable to deprive the fixed oils of color. The following process for this purpose is recommended by M. Brunner. The oil is first brought to the state of emulsion by strongly agitating it with water rendered mucilaginous by gum or starch; the emulsion is treated for each part of oil with two parts of wood charcoal, previously well heated and coarsely powdered, the finer particles being sifted out; the pasty mass is then completely dried at a heat not exceeding 212° F., and exhausted by cold ether in a percolator; finally, the ethereal solution, having been allowed to stand, in order that any charcoal present in it may subside, is submitted to distillation, so as to separate the ether, and the oil remains colorless in the retort. (*Journ. de Pharm.*, Sept. 1858.) M. Berlandt recommends the following method. Shake strongly for some minutes 900 parts of the fixed oil with 120 parts of water holding in solution 3 parts of potassium permanganate, allow the mixture to stand for some hours in a warm place, and then filter. The oil becomes colorless. (*Journ. de Pharm. et de Chim.*, Oct. 1867.)

2. OLEA VOLATILIA. [*Olea Destillata.*] *Volatile Oils.*

These are sometimes called *distilled oils*, from the mode in which they are usually procured; sometimes *essential oils*, from the circumstance that they possess, in a concentrated state, the properties of the plants from which they are derived. They exist in all odoriferous vegetables, sometimes pervading the plant, sometimes confined to a single part; in some instances contained in distinct cellules, and preserved after desiccation, in others formed upon the surface, as in many flowers, and exhaled as soon as formed. Occasionally two or more are found in different parts of the same plant. Thus, the orange-tree produces one oil in its leaves, another in its flowers, and a third in the rind of its fruit. In a few instances, when existing in distinct cellules, they may be obtained by pressure, as from the rind of the lemon and orange; but they are generally procured by distillation with water. (See page 908.) Some volatile oils, as those of bitter almond and mustard, are formed, during the process of distillation, out of substances of a different nature pre-existing in the plant.

The volatile oils are usually yellowish, but often brown, red, green, or blue, and occasionally colorless. There is reason, however, to believe that in all instances the color depends on for-

eign matter dissolved in the oils. Septimus Piesse has succeeded, by the fractional distillation of certain volatile oils, in separating a blue liquid, which, by repeated rectification, he has obtained quite pure. In this state it has the sp. gr. 0·910, and a fixed boiling point of 302·3° C. (576° F.), and yields a dense blue vapor having peculiar optical properties. He has named this principle *azulene*, and believes that upon it depends the blueness of volatile oils wherever existing. The yellowness of the oils he ascribes to the resin resulting from their oxidation, the green and brown colors to a mixture of azulene and resin in various proportions. The formula of azulene he gives as $C_{16}H_{26}O$. (*Chem. News*, Nov. 21, 1863, p. 245.) Gladstone names this blue coloring constituent *cærulein*, and says that it contains nitrogen and is colored green by acids and alkalies. The volatile oils differ from the fixed oils in not forming glycerides when treated with alkalies.

The volatile oils have a strong odor, resembling that of the plants from which they were procured, though generally less agreeable. Their taste is hot and pungent, and, when they are diluted, is often gratefully aromatic. The greater number are lighter than water; some are heavier; and their sp. gr. varies from 0·847 to 1·17. They partially rise in vapor at ordinary temperatures, diffusing their peculiar odor, and are completely volatilized by heat. When distilled alone, they almost always undergo partial decomposition. Heated in the open air, they take fire and burn with a bright flame attended with much smoke. Almost all those hitherto examined have the property of very decidedly deviating the plane of polarization of light, some in one direction, and some in the other; and advantage may sometimes be taken of this property to detect adulterations of one of these oils with another. Exposed at ordinary temperatures, they absorb oxygen, assume a deeper color, become thicker and less odorous, and are ultimately converted into resin.* This change takes place most rapidly under the influence of light. Before the alteration is complete, the remaining portion of oil may be recovered by distillation. Some of them form well-characterized acids by combination with oxygen.†

The volatile oils are largely hydrocarbons, although mixed with these are alcohol- or ketone-like bodies called *camphors*, and products of oxidation known under the general name of resins, and undoubtedly formed from the hydrocarbons. These hydrocarbons are generally known as *terpenes*, from oil of turpentine, which is taken as a type.‡ Wallach, to whom much of our recent knowledge on this subject is due, divides them into classes, as follows:

1. *True terpenes*, of the formula $C_{10}H_{16}$, of which we have two main groups: *a*, the *terpane* group, uniting with two molecules of haloid acid or four atoms of bromine; this group includes limonene, dipentene, sylvestrene, terpinolene, terpinene, and phellandrene, and its members boil between 175° and 185° C.; *b*, the *camphane* group, uniting with one molecule of haloid acid or two atoms of bromine; this group includes pinene, camphene, and fenchene, and its members boil between 151° and 161° C.

2. *Hemiterpenes*, of the formula C_5H_8, such as isoprene.

3. *Polyterpenes*, such as cedrene, cubebene, etc., of the formula $C_{15}H_{24}$; colophene, of the formula $C_{20}H_{32}$; and caoutchouc, of the formula $(C_{10}H_{16})_x$.

In addition to these naturally occurring hydrocarbons, we have a class of artificially pre-

* Some interesting observations have been made by M. Auguste Houzeau regarding the chemical influence of the atmosphere, which go to prove that, in reference at least to the air at Rouen, in France, which was the site of these observations, this influence varies in degree with the season, being greatest in the advanced spring or early summer (May and June), diminishing sensibly in summer and greatly in autumn, and increasing at the close of winter and the beginning of spring. If this be generally true, the change in oils, as well as in all other bodies oxidizable in the air, should be greatest at that period of the year when the atmospheric influence is greatest, namely, in May and June, and least when this is least, in the winter months. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 212–218.)

† *Recovery of volatile oils from their resinified condition.* A process for this purpose, employed by M. Curieux, is to treat the old resinified oil with a solution of borax and animal charcoal, these being first mixed to form a magma, the oil then added, and the mixture shaken for fifteen minutes. The borax unites with the resinous matter, and the magma, adhering to the sides of the vessel, leaves the oil clear and possessed of its original properties. (*A. J. P.*, Sept. 1858, p. 398.)

‡ *Olea ætherea sine terpeno* is the name proposed by Dr. Schweissinger for concentrated volatile oils made so by the removal of the non-fragrant hydrocarbon, and representing from two to thirty volumes of the ordinary essential oils. Thus, one volume of the concentrated oil represents two volumes of the oils of anise, cassia, fennel, gingergrass, mentha crispa, mentha piperita, cloves, sassafras, and star anise; two and one-half volumes of the oils of bergamot, caraway, and lavender; four volumes of cumin and rosemary; five volumes of thyme; six volumes of coriander; eight volumes of calamus; ten volumes of absinthe; twenty volumes of juniper; thirty volumes of angelica, lemon, and orange. It is asserted that these concentrated oils are more permanent, more soluble in alcohol and in water, have a finer odor, and are of constant composition, thus enabling the specific gravity and boiling point to be used as tests of purity. They should be kept in the dark. (*Pharm. Centralh.*, 1888, No. 25.) Under the name of "*terpeneless volatile oils*," similar products can now (1899) be found in the market; they are undoubtedly superior to the ordinary volatile oils both in odor and strength.

pared hydrocarbons known as *hydroterpenes*, such as dihydrodipentene from dipentene, menthene and carvomenthene from menthol and carvon.

The terpenes in general are practically insoluble in water, but soluble in alcohol, ether, chloroform, benzol, petroleum spirit, and the fixed and volatile oils. (Allen, *Commercial Organic Analysis*, 2d ed., vol. ii. p. 418.)

The volatile oils are very slightly soluble in water. Agitated with this fluid they render it milky, but separate upon standing, leaving the water impregnated with their odor and taste. This impregnation is more complete when water is distilled with the oils, or from the plants containing them. Trituration with magnesia or its carbonate renders them much more soluble, probably in consequence of their minute division. The intervention of sugar also greatly increases their solubility, and affords a convenient method of preparing them for internal use. The oils which contain no oxygen are scarcely soluble in diluted alcohol; and, according to De Saussure, their solubility generally in this liquid is proportionate to the oxygen which they contain. The volatile oils dissolve sulphur and phosphorus with the aid of heat, and deposit them on cooling. By long boiling with sulphur they form brown, unctuous, fetid substances, formerly called *balsams of sulphur*. They absorb chlorine, which converts them into resin and then combines with the resin. Iodine produces a similar effect. They are decomposed by the strong mineral acids, and unite with several of the acids from the vegetable kingdom. When treated with a caustic alkali, some of them are converted into resin, which unites with the alkali to form a kind of soap. Several of the metallic oxides, and various salts which easily part with oxygen, convert them into resin. The volatile oils dissolve many of the proximate principles of plants and animals, such as the fixed oils and fats, resins, camphor, and several of the alkaloids. Exposed to air and light, they acquire a decolorizing property, analogous to that of chlorine, which is ascribed by Faraday to their combination with the ozonized oxygen of the atmosphere. For some interesting observations on this property of the volatile oils, the reader is referred to papers by Dr. J. L. Plummer, of Richmond, Indiana, in *A. J. P.* (xxv.).*

The volatile oils, like the fixed oils, are mixtures of two or more principles, which differ in their point of volatilization or congelation, or in their composition. It is, however, impossible to separate them by distillation alone so as to obtain the several principles entirely pure. When, as often happens, the constituents congeal at different temperatures, they may be separated by compressing the frozen oil between folds of bibulous paper. The solid matter remains within the folds, and the fluid is absorbed by the paper, from which it may be separated by distillation with water. The name of *stearopten* has been proposed for the former, that of *elæopten* for the latter. The solid crystalline substances deposited by volatile oils upon standing are also called stearoptens. Some of them are denominated *camphors*, from their resemblance to true camphor. Some are isomeric with the oils in which they are formed, others are oxides or hydrates, alcohol-like in character. Certain oils, under the influence of water, deposit crystalline hydrates of the respective oils.

The volatile oils may be conveniently divided into three classes: 1, the *non-oxygenated oils*, consisting exclusively of carbon and hydrogen, as the oils of turpentine and copaiba; 2, the *oxygenated oils*, containing carbon, hydrogen, and oxygen, as oil of cinnamon and most of the aromatic oils; and, 3, the *sulphuretted oils*, containing sulphur, as the oils of horse-radish and mustard. The composition of those which are hydrocarbons simply has already been given.

The volatile oils are often sophisticated. Among the most common adulterations are fixed oils, resinous substances, and alcohol. The presence of the fixed oils may be known by the permanent greasy stain which they leave on paper, while that occasioned by a pure volatile oil disappears entirely when exposed to heat. They may also in general be detected by their comparative insolubility in alcohol. Both the fixed oils and resins are left behind when the adulterated oil is distilled with water. If alcohol be present, the oil will become milky when agitated with water in a graduated tube, and after the separation of the liquids the water will occupy more space and the oil less than before. The following method of detecting alcohol was proposed by M. Beral. Put twelve drops of the suspected oil in a perfectly dry watch-glass, and add a piece of potassium about as large as the head of a pin. If the potassium remains for twelve or fifteen minutes in the midst of the liquid, there is either no alcohol present, or less than 4 per cent. If it disappears in five minutes, the oil contains more than 4 per cent. of alcohol; if in less than a minute, 25 per cent. or more. M. Borsarelli employs calcium chloride for the

* See also the same journal (xxviii. 197) for some curious facts in relation to a repulsive influence exerted upon, and changes of color produced in, a mixture of potassium chromate and sulphuric acid, by different volatile oils, at sensible and sometimes considerable distances from the mixture, effected probably through the vapor of the oils.

same purpose. This he introduces in small pieces, well dried and perfectly free from powder, into a small cylindrical tube, closed at one end, and about two-thirds filled with the oil to be examined, and heats the tube to 212° F., occasionally shaking it. If there be considerable proportion of alcohol, the chloride will be entirely dissolved, forming a solution which sinks to the bottom of the tube; if only a very small quantity, the pieces will lose their form, and collect at the bottom in a white adhering mass; if none at all, they will remain unchanged. (*Journ. de Pharm.*, xxvi. 429.) J. J. Bernoulli proposes as a test dry potassium acetate, which remains unaffected in a pure oil, but will be dissolved if alcohol be present, and form a distinct liquid. (See *A. J. P.*, xxv. 82.) Mr. George A. Kelly suggests a simple test to detect alcohol: a quantity of the oil is placed in a capsule, which is put in a dark room, and a lighted match applied to it. The alcohol in the oil will burn with its characteristic lambent flame, whilst if no alcohol be present the flame will be yellow and smoky. The most dangerous adulterant of volatile oils is a liquid sold under some "fancy name," found in the markets of London and other large cities, and recommended for "reducing" essential oils; one specimen examined by John Barclay (*P. J. Tr.*, 1896, 463) had a delicate odor, and could be mixed with oils of lemon and bergamot without being detected by smell or taste. It was believed to be a *lævo-pinene*. There are good reasons for believing that similar liquids are used to an enormous extent.

Sometimes volatile oils of little value are mixed with the more costly. The taste and smell afford in this case the best means of detecting the fraud. The specific gravity of the oils may also serve as a test of purity. When two oils, of which one is lighter and the other heavier than water, are mixed, they may be separated by long agitation with this fluid, and will take a place corresponding to their respective specific gravities; but it sometimes happens that an unadulterated oil may thus be separated into two portions. The difference of apparent effect produced by iodine with the several oils has been proposed as a test; and bromine was employed for the same purpose by Prof. John M. Maisch, who used both these tests preferably in the state of ethereal solution; which, as it is liable to spontaneous change by keeping, should be prepared when wanted for use. According to Liebig, when iodine is made to act on a volatile oil, a portion of it combines with the hydrogen of the oil, forming hydriodic acid, while another portion takes the place of the lost hydrogen. Oil of turpentine may be detected by remaining in part undissolved when the suspected oil is treated with three or four times its volume of alcohol of the sp. gr. 0·84; or, according to M. Mero, by causing the suspected oil, when agitated with an equal measure of poppy oil, to remain transparent, instead of becoming milky, as it would do if pure. The latter test will not apply to the oil of rosemary. (*Journ. de Pharm.*, 3e sér., vii. 303.) G. S. Heppe suggests a very delicate test of oil of turpentine and most other non-oxygenated oils, when used to adulterate one of the oils containing oxygen. A piece of copper nitroprusside, of the size of a pin's head, is put into a little of the suspected oil in a test-tube, and heated until the liquid begins to boil. The boiling must be continued only a few seconds. If the oil be pure and oxygenated, the copper nitroprusside will become black, brown, or gray; if oil of turpentine or other non-oxygenated oil be present, the deposit will be green or bluish green, and the supernatant liquid colorless or yellowish. (*Chem. Gaz.*, April 15, 1857, p. 155; *Proc. A. P. A.*, 1858, p. 344.)

The different relations of the volatile oils to polarized light may, to a certain extent, be made available for the detection of adulterations, especially where the action of the adulterating oil is in an opposite direction to that of the oil adulterated. Thus, the oils of juniper, lavender, rosemary, rotate the plane of polarization to the left, while American oil of turpentine rotates it to the right; and if this should be added to one of the other oils it might in some degree neutralize their action, and thus offer one means for its detection. Unfortunately, the French oil of turpentine, from the juice of the *Pinus maritima*, acts strongly in the opposite direction. But the very strength of its left-rotatory power might lead to its detection by the abnormal increase of this power which it would impart to the oils in question. For a table of the direction and degree of the rotating power in several of the oils most employed, see *P. J. Tr.*, Oct. 1865. Synthetic or artificial volatile oils are now (1899) largely manufactured. They vary greatly in their resemblance to the natural products. They will be considered under their respective titles elsewhere.

Volatile oils may be preserved without change in small, well-stoppered amber-colored bottles, entirely filled with the oil, and secluded from the light.

Manufacture. Most of the volatile oils may be prepared by the general formula of the U. S. P. 1870: "Put the substance from which the Oil is to be extracted into a retort or other vessel suited for distillation, and add enough water to cover it; then distil by a regulated

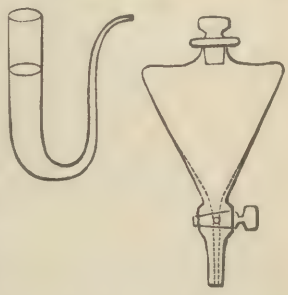
heat into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it."*

Under the general observations on the *Aquæ*, or *Waters*, will be found remarks upon the use of steam in preparing the Distilled Waters, which are to a considerable extent applicable also to the volatile oils.

The substances from which the volatile oils are extracted may be employed in either the recent or the dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt or by means of glycerin, as they afford little or no oil after desiccation. Most of the aromatic herbs, also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh; although it is thought by some that when moderately dried they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water till they are thoroughly penetrated by this fluid; and to facilitate the action of the water it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising, or other similar mechanical operation.

The water which is put with the subject of distillation into the still answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, though in most instances it readily rises with the vapor of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 100° C. (212° F.), and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 110° C. (230° F.). Recourse may also be had to a bath of strong solution of calcium chloride, or to an oil-bath, the temperature of which is regulated by a thermometer, as suggested by the Edinburgh College in their general directions, given above. Other oils, again, may be volatilized with water at a temperature below the boiling point; and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat, it has been recommended to suspend the substance containing the oil in a basket, or to place it upon a perforated shelf, in the upper part of the still, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object is to distil it *in vacuo*. Dr. Duncan stated that the most elegant volatile oils he had ever seen were prepared in this manner by Mr. Barry, the inventor of the process. The employment of steam heat also prevents injury; and the best volatile oils are now prepared in Philadelphia in this way. Steam can be very conveniently applied to this purpose by causing it to pass through a coil of tube, of an inch or three-quarters of an inch bore, placed in the bottom of a common still. The end at which the steam is admitted enters the still at the upper part, and the other end, at which the steam and condensed water escape, passes out laterally below, being furnished with a stopcock, by which the pressure of the steam may be regulated, and the water drawn off when necessary. In some instances it is desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition. This method is used in the preparation of the oil of bitter almond and the oil of mustard. The same method is applicable to the preparation of the distilled water.

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution when the mixed vapors are condensed; and if the proportion be very large, it is possible that no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled, and there will be danger of the substance in the still adhering to the sides of the vessel and thus becoming burnt. (See page 191.) Enough water should always be added to cover the solid material and prevent the latter accident. Dried plants require more water than the fresh and succulent. The whole amount of material in the still should not exceed three-fourths of its capacity, as otherwise there would be danger of the liquid boiling over. The form of the still has an influence over the quantity of water distilled, which depends more upon the extent of surface than upon the amount of liquid submitted to evaporation. By employing a high and rather narrow vessel we may obviate the disadvantage of an excess of water. (See p. 535.) Sometimes the proportion of oil in the substance employed is so small that it is wholly dissolved



* A large proportion of the volatile oils of European commerce is produced in Grasse, a town of France, twenty-five miles west of Nice. For an elaborate article on this industry and methods of preparation, see *Arch. d. Pharm.*, xxii. 473, abstracted in the *P. J. Tr.*, vol. xv. 468.

in the water distilled, even though the proportion of the liquid in the still is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant, till the quantity of oil exceeds the solvent power of the water. This process is called *cohobation.*

The more volatile of the oils pass with facility along with the steam into the neck of the common still; but some which are less volatile are apt to condense in the head and thus return into the still. For the distillation of the latter, a still should be employed with a very low head. (See cut on page 535.) As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tubes should be straight, rather than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, are rendered solid by a comparatively slight reduction of temperature, and that in the distillation of these the water employed for refrigeration should not be below 5·5° C. (42° F.).

The mixed vapors are condensed into a milky liquid, which is collected in a receiver, and, after standing for some time, separates into the oil and a clear solution of it, the former floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the fluid coming over has a milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florence receiver* may be used. This is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downward. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and, rising to the top, occupies the upper narrow part of the vessel, while the water remains at the bottom, and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates as long as the process continues; but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled. But, as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separatory* is usually employed for this purpose. It consists of a glass funnel, or globular vessel, furnished with a stopper, and prolonged at the bottom into a very narrow tube. The lower opening being closed, the mixed liquids are introduced and allowed to stand till they separate. The orifice at the bottom is then opened, and, the stopper at the top being a little loosened, so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than the water, it passes out of the separatory; if lighter, it remains within. According to George Leuchs, all oils obtained by distillation with water, even when perfectly clear, contain some water. (*A. J. P.*, 1873, p. 110.)

The water saturated with oil should be preserved for use in future distillations, as it can dissolve no more of the oil. One or more volatile acids are frequently found in the distilled water, as acetic, butyric, or valerianic; and Wunder has detected all three of these acids in the water distilled from chamomile flowers. (*Journ. für Prakt. Chem.*, lxiv. 499.) For an illustration of a cheap apparatus for distilling volatile oils by steam under slight pressure, see *Proc. A. P. A.*, 1894, 680.

According to Overbeck, all the volatile oils may be decolorized by distilling them from an equal weight of poppy-seed oil and a saturated solution of common salt. (*Archiv d. Pharm.*, lxxxiv. 149.)

When first procured, the oils have a disagreeable empyreumatic odor, from which they may be freed by allowing them to stand for some days in vessels loosely covered with paper. They should then be filtered and introduced into small opaque bottles, which should be well stoppered so as to exclude the air. When altered by exposure to air, they may sometimes be restored to their original appearance and quality by agitation with a little recently heated animal charcoal; and the same method may be employed for freeing them from adhering water.

The volatile oils have the medical properties of the plants from which they are derived; and, as their remedial application has been mentioned under the heads of these plants respectively, it is unnecessary to treat of it in this place. They may be administered upon a lump of sugar; or triturated with at least ten times their weight of sugar, forming *oleo-saccharates*, which are then dissolved in water; or made into emulsions with water, sugar, and gum arabic. In making emulsions with volatile oils, it has been recommended first to dissolve them in one of the fixed oils, the oil of almond for example, and then to emulsionize the oleaginous solution with syrup and gum arabic. For 100 parts of water, 15 of the almond oil in which the volatile oil is to be dissolved, 10 of powdered gum arabic, and 25 of syrup may be taken. (*Journ. de Pharm.*, Juin, 1864, p. 461.) The volatile oils are often kept dissolved in alcohol under the name of *essences*.* The following suggestions on preparing emulsions of the volatile oils may be useful. Oil of turpentine and other volatile oils, to be emulsionized in quantity, are most successfully treated by rubbing them with the powdered gum, and, when intimately mixed, adding at once, with rapid trituration, one and a half times the weight of the gum used, of water. By this treatment the volatile oil gets thoroughly divided before contact with water, and, if the quantity of water indicated be added at once, the emulsion will have the right preliminary consistence, and unite with and emulsionize the volatile oil. If, however, but a little water be added, this will seize on the gum, forming a pilular mass, and throwing the volatile oil out of union. Such an emulsion is more permanent when a little fixed oil is used.

OLEATA. Oleates.

(Ō-LĒ-Ā'TĄ.)

Oléates, *Fr.*; Oleate, *G.*

The oleates are a class of preparations which were introduced to the medical profession by Prof. John Marshall, F.R.S., in 1872. They are usually solutions of certain bases in oleic acid, and are made by triturating the solid substance with the oleic acid until it is dissolved. Whenever it is possible, the application of heat should be avoided; and it has been observed that the freshly precipitated oxides of the metals dissolve more readily than those which are old. The title *oleate* is probably the best that could be devised, although it must be understood that, as found in the Pharmacopœias, they are not pure chemical compounds, but merely compounds of the oxides or the alkaloids, as the case may be, with oleic acid dissolved in a great excess of the latter.†

Oleates may be made either by direct combination of the ingredients or by double decomposition. When made by the latter method, a good quality of oleic acid should be treated with the proper quantity of solution of sodium hydrate, to saponify it, any excess of the alkali being neutralized with a little tartaric acid. This soap solution is preferably used diluted.‡

* *Enfleurage.* This term is applied by the French to the impregnation of fixed oils and fatty matters with the odors of certain sweet-scented plants, such as jasmine, tuberose, and mignonette, the oils of which are so delicate and fugitive that they cannot well be separated by distillation. The process consists in exposing the fatty matter, placed in layers, in suitable frames, to the exhalations from the flowers, which are absorbed, and give their characteristic odor to the fat. Another plan is to expose alternate layers of the flowers, and of cotton impregnated with bland fixed oil, to the sun, and afterwards to express the oil from the cotton. (*A. J. P.*, xxix. 551.) The French sometimes give to the spirituous solutions made by extracting the odors from fats and oils with alcohol the name of *Essences*.

† Dr. L. Wolff has published a process for obtaining oleates, as follows. One part of Castile soap (sodium oleo-palmitate) is dissolved in eight parts of water, the solution so obtained is allowed to cool and stand for 24 hours, when there will be a considerable deposit of sodium palmitate, while the supernatant liquor, containing mostly sodium oleate, is drawn off and then decomposed with a concentrated solution of a metallic salt which, if obtainable, should contain no free acid to prevent the formation of free oleo-palmitic acid. The heavy deposit of oleo-palmitate so derived is drained off, pressed out in the strainer, and the adherent water evaporated in a water-bath; after this it is dissolved in about six to eight times its quantity of petroleum benzin, and the insoluble palmitate is left to subside, while the solution of oleate decanted therefrom is filtered off. The benzin evaporated will yield an oleate that is entitled to that name, as it is a chemical combination and will remain stable and efficacious. The oleates, so prepared, present an amorphous appearance, while the palmitates are of a crystalline character. (*A. J. P.*, 1881, p. 545.)

‡ *Sulpholeic Acid and Sulpholeates.* Sulpholeates, or salts produced by the combination of alkalies with sulpholeic acid, have come into use on account of their ability to dissolve many substances or hold them in suspension as emulsifying agents. Sulpholeic acid is prepared as follows. Castor, almond, or other fixed oil is gradually mixed with 30 or 40 parts of concentrated sulphuric acid, the mixture being cooled, if necessary, with ice, to prevent a rise of temperature above 50° C. (122° F.). The reaction, which at first is quite violent, is allowed to go on for from six to twelve hours, after which the mixture of acid and glycerin is decanted, the residue mixed with 100 parts of water, and this, after stirring, is also decanted. The resulting sulpholeic acid is converted into *alkaline sulpholeate* by the addition of caustic or carbonate of the required alkali. From this combination pure sulpholeic acid is obtained by careful decomposition with sulphuric acid, and agitation with benzin or ether, which leaves the acid on evaporation pure and anhydrous. (*Pharm. Rundschau*, 1885, p. 154.) According to Dr. A. Mueller Jacobs, when concentrated and in as pure a state as possible, the sulpholeates, as well as the free sulpho-acids themselves, mix readily and completely with a great variety of organic compounds, for instance with liquid hydrocarbons, particularly those of low boiling point, with chlorine, iodine, and bromine derivatives of the same, with ethers and alcohols, with organic sulphur compounds,

Prof. J. M. Good, in making the oleates of the alkaloids, proposes the use of sufficient oleic acid to dissolve the alkaloid and then diluting the solution with a bland fixed oil, such as almond oil. (*Proc. Missouri Pharm. Association*, 1891, p. 65.)

The *medical properties* of the oleates are, of course, dependent upon the base, so that these preparations may be considered the equivalents of the corresponding ointments, over which, however, they have certain advantages. They are much cleaner and more elegant in appearance. They seem to be more irritating than the ointments, and, unless diluted with an equal bulk of cotton-seed, olive, or other bland oil, are, when applied with friction, apt to provoke a cutaneous eruption or even pustulation. Dr. Marshall recommends that they be applied with a brush, or gently spread over the part with one finger.

OLEATUM HYDRARGYRI. U. S. (Br.) Oleate of Mercury.

(Ō-LĒ-Ā'TŬM HĪ-DRÄR'ĢĮ-RĪ.)

"Precipitated Mercuric Oleate, formed by the interaction of mercuric chloride and sodium oleate." *Br.*

Hydrargyri Oleas, *Br.*, Mercuric Oleate; Oléate de Mercure, *Fr.*; Oelsaures Quecksilber, *G.*

"Yellow Mercuric Oxide, thoroughly dried, *two hundred grammes* [or 7 ounces av., 24 grains]; Oleic Acid, *eight hundred grammes* [or 28 ounces av., 96 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Introduce the Oleic Acid into a capacious mortar, and gradually add to it the Yellow Mercuric Oxide by sifting it upon the surface of the Acid, and incorporate it by continuous stirring. Then set the mixture aside in a warm place, at a temperature not exceeding 40° C. (104° F.), and stir frequently, until the Oxide is dissolved." *U. S.*

"Mercuric Chloride, 1 *ounce* (Imperial) or 32 grammes; Hard Soap, powdered, 2 *ounces* (Imp.) or 64 grammes; Oleic Acid, 1 *fl. drachm* (Imp. meas.) or 4 cubic centimetres; Distilled Water, boiling, *a sufficient quantity*. Dissolve the Mercuric Chloride in *ten fluid ounces* (Imp. meas.) or three hundred and twenty cubic centimetres of the Distilled Water. Triturate the Oleic Acid with the Hard Soap, and dissolve the product in *eleven fluid ounces* (Imp. meas.) or three hundred and fifty-two cubic centimetres of the Distilled Water. Mix the solutions; boil for ten minutes; set aside for the mercuric oleate to deposit; decant the supernatant liquid; wash the precipitated oleate with hot Distilled Water until the decanted liquid affords little or no reaction for chloride, and then dry it on a water-bath." *Br.* It is "A substance of unctuous consistence, having a light greyish-yellow color, liable to darken by keeping. It has a somewhat saponaceous odor." *Br.*

This preparation was introduced by Prof. John Marshall in 1872. If made from oleic acid which has been purified from the usual contaminations (palmitic and stearic acids), it is a clear yellowish liquid of a thick consistence and having the peculiar odor of oleic acid. As usually seen, however, it is of the consistence and appearance of petrolatum, due to the presence of small quantities of mercuric palmitate and stearate. (See *Acidum Oleicum*, p. 75.) The formula of a normal oleate of mercury would be $(C_{18}H_{33}O_2)_2Hg$. For its formation we should reckon for every 25 parts of mercuric oxide from 65 to 66 parts of oleic acid. Free oleic acid is intentionally present in this U. S. preparation, which is known frequently as "20 per cent. oleate of mercury." In making this preparation, care must be exercised in the selection of the oleic acid, and to avoid exceeding the degree of heat directed in the official process; indeed, our experience has been that it keeps better if made by the cold process,—*i.e.*, by simply mixing the freshly precipitated yellow oxide with the oleic acid, and allowing them to stand

such as carbon disulphide, oil of mustard, mercaptane, etc., and with all essential oils. They also dissolve varying quantities of sulphur, iodoform, solid hydrocarbons, such as naphtalin, naphtol, anthracine, and paraffin, the terpenes and camphenes. These liquid mixtures of sulpholeates and other bodies have the property of forming emulsions or even clear solutions with water. The limit of miscibility (in form of emulsion) or solubility varies considerably, and depends both on the degree of concentration of the sulpholeate serving as a menstruum, and on certain little understood properties of the substances mixed with it. For instance, 100 parts of pure neutral sodium sulpho-ricinoleate yield with 50 parts of ether an almost clear solution; so also with 30 parts of volatile oil of mustard, 30 parts of petroleum benzin, 100 parts of coal-tar benzol, 40 parts of carbon disulphide, etc. Larger quantities of these substances yield permanent milky emulsions, foaming when diluted and shaken with water.

This peculiar behavior of the sulpholeates, and particularly of the sulpho-ricinoleate of alkalies, towards many otherwise insoluble or difficultly soluble substances, as well as their pronounced saponaceous character and the great readiness with which they take up and combine with liquids, is said to render them eminently suitable for various technical and medical uses.

The liquid alkaline salt which forms the solvent is termed *polysolve* by Dr. A. Mueller Jacobs, who believes that the sulpholeate mixtures will be found excellent solvents for substances the employment of which in a concentrated condition is accompanied by certain untoward effects, or may serve as vehicles in place of vaseline, oils, glycerin, etc., in perfumery, soap-making, or pharmacy. (*Amer. Druggist*, 1884, p. 22.)

at ordinary temperatures until the precipitate has dissolved. The British preparation is modelled after Shoemaker's process. The precipitated mercuric oleate is difficult to free from water, and is prone to change. In time, even with the best oleic acid that can be procured, some decomposition will take place, and metallic mercury will be found at the bottom of the containing bottle. The rapidity of the change will be in proportion to the impurities in the oleic acid and the degree of heat employed. Beringer's process, by the double decomposition of potassium oleate and mercuric nitrate, is commended by Edel. (See *West. Drug.*, 1894, 85.)

Medical Properties. This preparation may often be substituted with advantage for mercurial ointment, which it closely resembles in its medical properties, except that it is more readily absorbed, and therefore more effective. It has been especially commended by Dr. Marshall in cases of *chronically inflamed joints*, and in *hordeolum*, *indurations after abscesses*, and various other forms of superficial local inflammations of a slow type; also in *sycosis*, *tinea*, *psoriasis*, *eczema*, and as a constitutional alterative in *hereditary syphilis*. For many purposes it is much improved by dissolving in every drachm of it one grain of morphine. The alkaloid itself must be used in such cases, as its salts are not soluble in oleic acid.

OLEATUM VERATRINÆ. U. S. Oleate of Veratrine.

(Ō-LĒ-Ā'TŬM VĔR-Ą-TRĪ'NÆ.)

Oléate de Vératrine, *Fr.;* Oelsaures Veratrin, *G.*

"Veratrine, *two grammes* [or 31 grains]; Oleic Acid, *ninety-eight grammes* [or 3 ounces av., 200 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Veratrine with a small quantity of Oleic Acid, in a warm mortar, to a smooth paste. Then add the remainder of the Oleic Acid, previously warmed, and stir frequently, until the Veratrine is dissolved." *U. S.*

This preparation is simply a solution of the alkaloid in oleic acid. It may be substituted for Unguentum Veratrinæ, but is exactly half the strength. It is well adapted for obtaining all the advantage that can be derived from an application of veratrine by inunction. (See *Veratrinæ.*) When the veratrine is to be used as a counter-irritant, the ointment is preferable, because less favorable to the absorption of the alkaloid. The *Oleate of Morphine* is made in the same way.

OLEATUM ZINCI. U. S. Oleate of Zinc.

(Ō-LĒ-Ā'TŬM ZĬN'CĪ.)

"Zinc Oxide, *fifty grammes* [or 1 ounce av., 334 grains]; Oleic Acid, *nine hundred and fifty grammes* [or 33 ounces av., 223 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Introduce the Oleic Acid into a capacious capsule, and gradually add to it the Zinc Oxide by sifting it upon the surface of the Acid, and incorporate it by continuous stirring. Set the mixture aside for a few hours, and then heat it on a water-bath, frequently stirring, until the Oxide is dissolved." *U. S.*

This oleate will be found for the first time in the U. S. Pharmacopœia of 1890. It was official in the British Pharmacopœia of 1885. (See *Unguentum Zinci Oleatis.*) It is intended to be mixed with petrolatum or soft paraffin and applied externally.

OLEORESINÆ. Oleoresins.

(Ō-LĒ-Ō-RĔS'Ī-NÆ.)

Oléo-résines, Extraits éthérés, *Fr.;* Oelharze, Aetherische Extrakte, *G.*

The oleoresins, as a class of Preparations, were introduced into the U. S. Pharmacopœia at the revision of 1860, having been previously classed with the Fluid Extracts. Their peculiarity is that they consist of principles which, when extracted by means of ether, retain a liquid or semi-liquid state upon the evaporation of the menstruum, and at the same time have the property of self-preservation, differing in this respect from the fluid extracts, which require the presence of alcohol in order to prevent decomposition. They consist chiefly, as their name implies, of oil, either fixed or volatile, holding resin and sometimes other active matter in solution. Their preparation is very simple, consisting in the exhaustion of the medicine employed with ether, by means of percolation, and the subsequent evaporation of the menstruum. In consequence of the great volatility of ether, it may in great measure be recovered by distillation, thus very materially diminishing the costliness of the process. It is proper not

to continue the heat necessary for the distillation till the whole of the ether is driven over, lest, towards the close, a portion of the volatile matters also should pass, and the strength of the oleoresin be impaired. Hence in every instance the last portions of the menstruum are allowed to separate by spontaneous evaporation. Benzin has been proposed as a substitute for ether in these preparations, but should not be permitted to supersede it until officially sanctioned.

OLEORESINA ASPIDII. U. S. (Br.) Oleoresin of Aspidium.

(Ō-LĒ-Ō-RĒS'Ī-NĄ ĄS-PĬD'Ī-Ī.)

Extractum Filicis Liquidum, *Br.;* Oleoresina Filicis, *Pharm.* 1870; Liquid Extract of Male Fern, Oil of Fern; Extractum Filicis, *P. G.;* Oleum Filicis Maris; Huile (Extrait éthéré) de Fougère mâle, *Fr.;* Wurmfarnextrakt, Wurmfarnöl, *G.*

"Aspidium, recently reduced to No. 60 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity.* Put the Aspidium into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with Ether, added in successive portions, until the drug is exhausted. Recover the greater part of the Ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining Ether to evaporate spontaneously. Keep the Oleoresin in a well-stoppered bottle. NOTE.—Oleoresin of Aspidium usually deposits, on standing, a granular-crystalline substance. This should be thoroughly mixed with the liquid portion before use." *U. S.*

"Exhaust Male Fern Rhizome, in No. 20 powder, with Ether, by percolation; evaporate the Ether from the clear percolate on a water-bath or by distillation, until an oily Extract remains." *Br.*

This is the only preparation of male fern which should be used; in its making male fern which is green in color and recently collected should be employed. It is a thick, dark green liquid, usually containing a granular deposit of *filicic acid*, which is regarded as the active ingredient and should not be separated. Wm. G. Greenewalt found both the liquid and the sediment effective tænicides, the sediment being somewhat the more active. It has the odor of fern, and a nauseous, bitterish, somewhat acrid taste. According to Hayes, when an absolutely dry root and an anhydrous ether (containing but little alcohol) of a specific gravity below 0·728 are used, the oleoresin remains clear. Kramer states that a very active extract of male fern may be prepared by exhausting with ether the fresh juicy rhizomes collected in May or October freed from scales and cut into small pieces. The ethereal tincture should be kept in a cool place until wanted, when the necessary quantity should be converted into extract. One dose, two to four drachms, of such an extract is said to have always produced satisfactory results. (*Pharm. Cent.*, xxv. 578.) Dose, from one-half to one fluidrachm (1·9–3·75 C.c.), administered in gelatin capsules.

OLEORESINA CAPSICI. U. S. Oleoresin of Capsicum.

(Ō-LĒ-Ō-RĒS'Ī-NĄ CĂP'SĬ-CĪ.)

Oléorésine (Extrait éthéré) de Capsique, *Fr.;* Spanischpfeffer-Oelharz, *G.*

"Capsicum, in No. 60 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity.* Put the Capsicum into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with Ether, added in successive portions, until the drug is exhausted. Recover the greater part of the Ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining Ether to evaporate spontaneously. Then pour off the liquid portion, transfer the remainder to a strainer, and when the separated fatty matter (which is to be rejected) has been completely drained, mix the liquid portions together. Keep the Oleoresin in a well-stoppered bottle." *U. S.*

The active principle of capsicum, called *capsicin*, is very soluble in ether, and is wholly extracted in the process. Its precise nature has not been determined. (See *Capsicum.*) After the concentration of the ethereal solution, a solid fatty matter separates on standing, but a portion of fixed oil probably still remains. The preparation is a very thick liquid, capable, however, of being dropped, of a dark reddish-brown color, and, though opaque in mass, yet transparent in thin layers. It has not very decidedly the odor of capsicum, but to the taste is intensely pungent. W. C. Alpers found a capsicum which yielded 16 per cent. of oleoresin; the statement has been frequently made that 5 per cent. was the usual yield. (*Merck's Report*, 1896, 593.) It may be usefully employed to give locally stimulant properties to substances administered internally in a pilular form, in cases of *gastric insensibility* and excessive *flatulence.*

Dr. H. C. Wood has seen one drop given three times a day produce cystic irritation and strangury. The dose is from one-fourth to one minim (0·015–0·06 C.c.). It may be used also as a powerful rubefacient, diluted with olive oil or soap liniment.

OLEORESINA CUBEBÆ. U. S. Oleoresin of Cubeb.

(Ō-LĒ-Ō-RĒS'Ī-NĄ CŪ-BĒ'BÆ.)

Extractum Cubebarum, *P. G.;* Extractum Cubebæ Ætherеum; Oléorésine de Cubèbe, *Fr.;* Aetherisches Kubebenextrakt, *G.*

"Cubeb, in No. 30 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity.* Put the Cubeb into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with Ether, added in successive portions, until the drug is exhausted. Recover the greater part of the Ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining Ether to evaporate spontaneously. Keep the product in a well-stoppered bottle. NOTE.—Oleoresin of Cubeb deposits, after standing for some time, a waxy and crystalline matter, which should be rejected, only the liquid portion being used." *U. S.*

This oleoresin consists mainly of the volatile oil and resin, with a portion of the cubebin and waxy matter of the cubeb. The consistence differs according to the character of the cubeb employed, its degree of fluidity being proportionate to the amount of volatile oil contained in the medicine. The color is usually blackish brown, with more or less of a greenish hue, according to the quantity of chlorophyll present, which varies with the character of the cubeb, and with that of the menstruum, pure ether extracting the green coloring matter preferably, while ordinary alcoholic ether extracts also the brown. Cubeb yields from one-eighth to one-fifth of its weight of the oleoresin. The preparation deposits waxy matter and crystals of cubebin on standing, which should be separated; its efficacy is not impaired on this account. It was first introduced into use by Prof. Procter. (*A. J. P.*, xviii. 168.)

From carefully conducted experiments by Mr. F. V. Heydenreich, it would appear that, of the various constituents of cubeb contained in the official oleoresin, the cubebin has no perceptible effect in the dose of the medicine ordinarily given, that the volatile oil is simply stimulant and carminative, and, finally, that the soft resin has all the diuretic properties of the cubeb. Of the last-mentioned ingredient, twenty grains (1·3 Gm.) given every two hours till five doses were taken considerably increased the secretion of urine, producing at the same time a slight burning sensation in the passage, which ceased with the diuretic action. Pushed beyond this amount, it occasioned severe irritation of the urinary passages, with some fever. (*Ibid.*, Jan. 1868, p. 42.)

This oleoresin, as it occurs in the market, often has a decided ethereal odor, and is of a thin consistence. In one specimen three-eighths of its weight of ether were lost in a short time by spontaneous evaporation. As the cubeb is very nearly exhausted by the ether before the whole of the latter has passed, there is a considerable expenditure of that liquid for the sake of a scarcely appreciable portion of the active matter. In case of excess of ether in the oleoresin, it should be allowed to escape by spontaneous evaporation in a capsule. (*Ibid.*, May, 1860.)

The dose of this oleoresin is from five to thirty minims (0·3–1·9 C.c.), which may be given suspended in water, or mixed with powdered sugar.

OLEORESINA LUPULINI. U. S. Oleoresin of Lupulin.

(Ō-LĒ-Ō-RĒS'Ī-NĄ LŪ-PŪ-LĪ'NĪ.)

Oleoresina Lupulinæ, *Pharm.* 1870; Extractum Lupulini Ætherеum; Oléorésine de Lupuline, *Fr.;* Aetherisches Lupulinextrakt, *G.*

"Lupulin, *one hundred grammes* [or 3 ounces av., 331 grains]; Ether, *a sufficient quantity.* Put the Lupulin into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug very lightly, and percolate slowly with Ether, added in successive portions, until the drug is exhausted. Recover the greater part of the Ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining Ether to evaporate spontaneously. Keep the Oleoresin in a well-stoppered bottle." *U. S.*

Lupulin yields its volatile oil and resin, as well as any other active principle it may contain, to ether, and the resulting oleoresin constitutes about three-eighths, or somewhat less than one-

half, of the original drug. It is of a very thick, semi-fluid consistence, so thick, indeed, that it cannot be conveniently administered by drops. Its color is almost black in mass, but a rich reddish brown in thin layers. It has the odor and taste of lupulin, and possesses all its medical properties. The dose is from two to five grains (0·13–0·33 Gm.), and may be most conveniently administered in the form of pill, made with powdered liquorice root, or other proper excipient.

OLEORESINA PIPERIS. U.S. Oleoresin of Pepper.

(Ō-LĘ-Ō-RĒŞ'Ị-NĄ PĪ'PĘ-RĬS.)

Extractum Piperis Fluidum, *U. S.* 1850; Fluid Extract of Black Pepper; Oléorésine de Poivre noir, *Fr.;* Aetherisches Pfefferextrakt, *G.*

"Pepper, in No. 60 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether *a sufficient quantity.* Put the Pepper into a cylindrical glass percolator, provided with a stopcock, and arranged with a cover and receptacle for volatile liquids. Press the drug firmly, and percolate slowly with Ether, added in successive portions, until the drug is exhausted. Recover the greater part of the Ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, set this aside until the remaining Ether has evaporated, and the deposition of crystals of piperin has ceased. Lastly, separate the Oleoresin from the piperin by expression through a muslin strainer. Keep the Oleoresin in a well-stoppered bottle." *U. S.*

A substance has long been in use under the name of *oil of black pepper*, consisting mainly of the volatile oil, fixed oil, and resin of the pepper, and belonging, therefore, to the oleoresins. As usually found, it is almost black, and of a thickish consistence, and is a residue of the process for preparing piperin. The official oleoresin has the same general character, but is more fluid and of more uniform strength, and should, therefore, be preferred. It contains almost all the volatile oil and acrid resin of black pepper, with little of the piperin; and, as the last-mentioned principle, when quite pure, is of doubtful efficacy, the extract may be considered as representing the virtues of the fruit. The color is greener than that of the common oil of black pepper, and not so dark, owing to the fact that ether dissolves the green more readily than the brown coloring matter. A pound of black pepper yields about six drachms of the oleoresin. Dose, from one-fourth to one minim (0·015–0·06 C.c.), in emulsion or pill.

OLEORESINA ZINGIBERIS. U.S. Oleoresin of Ginger.

(Ō-LĘ-Ō-RĒŞ'Ị-NĄ ZĮN-ĢĬB'Ę-RĬS.)

Extractum Zingiberis Æthereum; Oléorésine (Piperoide) de Gingembre, *Fr.;* Aetherisches Ingwerextrakt, *G.*

"Ginger, in No. 60 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity.* Put the Ginger into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with Ether, added in successive portions, until the drug is exhausted. Recover the greater part of the Ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining Ether to evaporate spontaneously. Keep the Oleoresin in a well-stoppered bottle." *U. S.*

In the U. S. formula of 1870, for this preparation alcohol was used in connection with ether, on the score of economy; it was added in order to displace the ether and thus save an unnecessary expenditure of the more costly fluid. A little of the alcohol mixed with the ether at their surface of contact. In the present process alcohol is not used, and there is no good reason for making an exception to the general formula in this case. The whole of the virtues of the root are extracted in this preparation, as the residuary ginger is nearly or quite tasteless, The oleoresin constitutes about 5 per cent. of the dried root. It is the *piperoid of ginger* of M. Beral. (*Soubeiran's Traité de Pharm.*, i. 371.) It is a clear, dark-brown liquid, of a thick consistence (though capable of being dropped), with the flavor of ginger, and intensely pungent. Its dose should not exceed a minim (0·06 C.c.), and should be much diluted.

OLEUM ADIPIS. U.S. Lard Oil.

(Ō'LĘ-ŬM ĂD'Ị-PĬS.)

"A fixed oil expressed from Lard at a low temperature." *U. S.*

This oil is made in large quantities in this country by exposing lard to low temperatures and then subjecting it to very powerful pressure. In this way the stearin of the lard is separated from the olein, the latter oozing out from the presses in the form of a yellowish-white oil, whilst the stearin is thrown into the market in hard cakes, and is largely used in making soap. (See

Adeps.) The exportation of lard from the United States for the year ending June 30, 1897, amounted to 476,958,201 pounds, valued at $24,877,044, and that of lard oil to 1,214,997 gallons, valued at $519,658. (*U. S. Treasury Statistical Reports.*)

Properties. Lard oil is "a colorless or pale yellow, oily liquid, having a peculiar odor, and a bland taste. Specific gravity, 0·910 to 0·920 at 15° C. (59° F.). At a temperature a little below 10° C. (50° F.) it usually commences to deposit a white, granular fat, and at or near 0° C. (32° F.) it forms a semi-solid, white mass. When it is brought in contact with concentrated sulphuric acid, a dark reddish-brown color is instantly produced. If 5 C.c. of the oil be thoroughly shaken, in a test-tube, with 5 C.c. of an alcoholic solution of silver nitrate (made by dissolving 0·1 Gm. of silver nitrate in 10 C.c. of deodorized alcohol, and adding 2 drops of nitric acid), and the mixture heated for about five minutes in a water-bath, the Oil should remain nearly or quite colorless, not acquiring a reddish or brown color, nor should any dark color be produced at the line of contact of the two liquids (absence of more than about 5 per cent. of *cotton seed oil*). If 5 C.c. of the Oil, contained in a small flask, be mixed with a solution of 2 Gm. of potassium hydrate in 2 C.c. of water, then 5 C.c. of alcohol added, and the mixture heated for about five minutes on a water-bath, with occasional agitation, a perfectly clear and complete solution should be formed, which, on dilution with water to the volume of 50 C.c., should form a transparent, light yellow liquid, without the separation of an oily layer (absence of appreciable quantities of *paraffin oils*)." *U. S.* It is not pure olein, but contains varying proportions of stearin, and is sometimes adulterated with paraffin oil. It has been introduced into the Pharmacopœia for the purpose of using in ointment of mercuric nitrate.

Medical Properties. Lard Oil is a bland, fatty liquid, destitute of active medical properties, and is official solely for pharmaceutical purposes.

OLEUM ÆTHEREUM. U. S. Ethereal Oil.

(Ō'LĒ-ŬM Æ-THĒ'RĒ-ŬM.)

"A volatile liquid, consisting of equal volumes of Heavy Oil of Wine and Ether." *U. S.*

Oleum Vini; Heavy Oil of Wine; Huile d'Éther, Huile de Vin pésante, Huile volatile éthérée, *Fr.;* Schweres Weinöl, *G.*

"Alcohol, *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]; Sulphuric Acid, *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]; Distilled Water, *twenty-five cubic centimeters* [or 406 minims]; Ether, *a sufficient quantity.* Add the Acid slowly to the Alcohol, mix them thoroughly, and allow the mixture to stand, in a closed flask, for twenty-four hours, or until the liquid is clear; then pour the clear liquid into a tubulated retort of such capacity that the mixture shall nearly fill it. Insert a thermometer through the tubulure, so that the bulb shall be deeply immersed in the liquid, and, having connected the retort with a well-cooled condenser, and also having connected with the receiver a bent glass tube for conducting the uncondensed gases into water, distil, by means of a sand-bath, at a temperature between 150° and 160° C. (302°–320° F.), until oily drops cease to come over, or until a black froth, which forms on the surface, begins to rise in the retort. Separate the yellow, ethereal liquid from the distillate, and expose it to the air for twenty-four hours, in a shallow capsule. Then transfer it to a wet filter, and, when the watery portion has drained off, wash the oil which is left on the filter with the Distilled Water, which should be as cold as possible. When this also has drained off, transfer the oil to a graduated measure, and add to it an equal volume of Ether. Keep the product in small, glass-stoppered vials, in a cool place." *U. S.*

In the consolidation of the British Pharmacopœias this valuable remedy was omitted, partly on account of the uncertainty as to its special antispasmodic virtues, partly from its expensiveness when properly made and its liability to spontaneous change, and partly, moreover, because not only is it often adulterated, but other compounds are substituted for it.

The object of allowing the mixture of acid and alcohol to stand is to allow the lead sulphate which is usually present in commercial sulphuric acid to deposit, for, according to Dr. Squibb, its presence in the retort causes the mixture to froth over, and this necessitates a suspension of the process so much sooner as greatly to lessen the amount of product the materials are capable of affording. The increase of oil resulting from this simple modification of the process is said to be one-third. The temperature has been slightly decreased. By wetting the filter, the oil is prevented from passing along with the water. Finally, the oil is now ordered to be diluted with an equal measure of stronger ether, as this has been found to contribute greatly to its preservation.

When alcohol is distilled with a large excess of sulphuric acid, there are formed towards the close of the distillation sulphurous acid, heavy oil of wine, olefiant gas, and resino-carbonaceous matter. The product of the distillation is generally in two layers, one consisting of water holding sulphurous acid in solution, and the other, of ether containing the heavy oil of wine. According to the experience of Dr. Squibb, the sp. gr. of these two layers is so nearly equal that sometimes one and sometimes the other is uppermost: so that the direction in the old formula to separate the supernatant liquor is incorrect, and has been superseded by the present, to separate the yellow ethereal liquid,—the color and other sensible properties being considered sufficiently distinctive. After separation, the liquid is exposed for twenty-four hours to the air, in order to dissipate the ether by evaporation; and the oil which is left is washed with water, to deprive it of all traces of sulphurous acid.

The nature and mode of formation of heavy oil of wine are generally believed to be the following. It has been explained in a preceding article that, in the early stage of the distillation of a mixture of sulphuric acid and alcohol, sulphovinic acid, $C_2H_5HSO_4$, is formed. During its progress this is decomposed so as to yield ether. When, however, the alcohol is distilled with a large excess of sulphuric acid, the sulphovinic acid is decomposed so as to form a small quantity of the *heavy oil of wine*. This is a mixture of ethyl sulphate, $(C_2H_5)_2SO_4$, ethyl sulphite, $(C_2H_5)_2SO_3$ (the sulphurous acid having been formed by reduction of sulphuric acid, as it always is when ethylene is formed from alcohol), with polymeric forms of ethylene, C_2H_4. Two of these forms are known: *etherin*, a solid fusing at 110° C. and boiling at 260° C., and *etherol*, a liquid. The latter is by some considered to have the formula $C_{16}H_{32}$ or $(C_2H_4)_8$, and mixed with the former constitutes the *light oil of wine*, which is produced when the heavy oil is heated with water and alkaline solutions. In this case sulphovinic acid is reproduced, and the separated *etherol* floats on the surface as an oily substance. *Light oil of wine*, as thus obtained, is a pale-yellow oil. As ordinarily procured in the process for preparing ether, it contains a portion of that substance, admixed, according to Hartwig (*J. Pr. Chem.* [2], 23, 449), with ketones like ethyl-amyl ketone and methyl-hexyl ketone and mixed ethers like ethyl-amyl ether. When the pure light oil of wine is kept, it deposits a stearopten (the *etherin* mentioned above) called concrete oil of wine, or oil of wine camphor; after which the oil is changed, and takes the name of etherol. *Etherol* is a pale-yellow oily liquid, having an aromatic odor. Its sp. gr. is 0·921, boiling point 280° C. (536° F.), and freezing point —35° C. (—31° F.). It communicates a greasy stain to paper. *Concrete oil of wine*, or *etherin*, crystallizes in long, transparent, brilliant, tasteless prisms, soluble in alcohol and ether, insoluble in water, and having the sp. gr. 0·980. Dr. Squibb takes a different view of the composition of ethereal oil, and believes it, instead of a sulphate or a mixture of sulphate and sulphite, to be a sulphovinate of a hydrocarbon radical; and for this reason, that it fails, especially when pure and recent, to give any of the characteristic reactions of sulphuric acid or the sulphates. (*A. J. P.*, 1861.)*

Properties. The undiluted *ethereal oil* (*heavy oil of wine*) is a yellowish neutral liquid, possessing an oleaginous consistence, a penetrating aromatic odor, and a rather sharp and bitter taste. It boils at 280° C. (536° F.). Its sp. gr. is, according to the U. S. P. 1850, 1·096; according to the London College, after Mr. Hennell's results, 1·05. The density obtained by Dr. Squibb, by following the old formula of the U. S. Pharmacopœia exactly, was 1·129. By Dumas and Sérullas its density is stated to be as high as 1·133, which is probably the more correct number for the *pure* oil. When dropped into water it sinks, assuming the form of a globule. It dissolves sparingly in cold water, moderately in hot water, and readily in alcohol and ether. It is devoid of acid reaction, the sulphuric and sulphurous acids present in it being in the form of neutral salts. The sulphuric acid present is not precipitated by the usual reagents for this acid; because sulphovinic acid is formed, and all the sulphovinates are soluble in water. The U. S. ethereal oil of the present Pharmacopœia is the proper oil diluted with an equal volume of stronger ether. This gives it an ethereal odor in addition to that characteristic of the pure oil, and considerably reduces its sp. gr., which is now stated at 0·910 at 15° C. (59° F.). The process by which the official oil of wine is formed yields but a small

* Valuable papers have been contributed by Mr. C. Lewis Diehl and Prof. John M. Maisch on this official preparation,—the former in *Proc. A. P. A.*, 1864, the latter in *A. J. P.*, 1865, p. 160, to which we refer those especially interested in its manufacture. In Mr. Diehl's paper valuable suggestions are made in reference to the mode of reheating so as properly to regulate the temperature. An important practical fact was stated by Prof. Maisch, that the ethereal oil, in contact with water, undergoes a decomposition into light oil of wine and sulphovinic acid, rapidly and completely if the water is hot or if solution of an alkali or of an alkaline carbonate is used, and more slowly with cold water. Hence the inference that the washing of the ethereal oil, directed at the close of the U. S. process, should be completed as rapidly as possible.

product, being, according to the Pharmacopœia of 1870, only about six fluidrachms, or somewhat more than a fortieth, by measure, of the alcohol employed.

In the official ethereal oil, the heavy oil of wine is not only diluted with an equal measure of ether, but is mixed also with variable proportions of free light oil of wine. This fact accounts for the different densities assigned to the heavy oil. The heavy oil undiluted is liable to spontaneous change by time, not only being rendered brown, but also being chemically altered so as to separate into two layers. But this tendency is in great measure obviated, in the official ethereal oil, by the preservative influence of the ether. It may be kept long without other appreciable change than the acquisition of a brown hue, which does not interfere with its medical virtues. It should not, when tested by dry litmus paper, evince the presence of free acid.

Medical Properties and Uses. Dr. Hobart A. Hare has found that the heavy oil of wine produces in mammals a rise in the arterial pressure and pulse-rate, followed after sufficient doses by a fall. The rise in the pressure was the result of a stimulant influence upon the vasomotor centre, whilst the fall of the pressure appeared to be due to a widening out of the blood-paths by a direct paralysis of the coats of the vessels. Dr. Hare also found that very large doses paralyze the heart by a direct action on the muscle, but he did not determine the exact influence of small doses. The toxic properties of the heavy oil of wine were shown to be very feeble, and the research seems to prove that the small quantity of the heavy oil of wine contained in Hoffmann's anodyne cannot exert a very pronounced influence upon the human system. It probably has, however, a slight stimulative, calmative effect, since clinical experience indicates that compound spirit of ether is a more persistent and powerful antispasmodic and nervous stimulant than is an equivalent amount of ether and alcohol. The article sold in commerce as heavy oil of wine is too often a mixture of alcohol and ether containing but a trace of the oil. It is used only for the preparation of compound spirit of ether, but there can be no justification of the action of the chemist in furnishing a fraudulent article.

OLEUM AMYGDALÆ AMARÆ. U. S. Oil of Bitter Almond.

(Ō'LḘ-ŬM Ą-MŸG'DĄ-LÆ Ą-MĀ'RÆ.)

"A volatile oil obtained from Bitter Almond by maceration with water, and subsequent distillation. It should be kept in small, well-stoppered bottles, protected from light." *U. S.*

Oleum Amygdalarum (Amararum) Æthereum; Essence d'Amandes amères, *Fr.*; Bittermandelöl, *G.*

When bitter almonds are expressed, they yield a bland fixed oil; and the residuary cake, reduced to powder by grinding, and submitted to distillation with water, yields a volatile oleaginous product, commonly called oil of bitter almond. This does not pre-exist in the almond, but is produced by the reaction of water upon the amygdalin contained in it, through the intervention of another constituent, denominated emulsin (see *Amygdala Amara*), according to the reaction $C_{20}H_{27}NO_{11} + 2H_2O = C_7H_6O + 2(C_6H_{12}O_6) + HCN$. It is obtained also by the distillation of the leaves of the cherry-laurel, and of various products of the genera Amygdalus, Cerasus, Prunus, etc. Mr. Whipple obtained, upon an average, from the ground bitter almond cake, 1·35 per cent. of the oil. (*P. J. Tr.*, x. 297.) Pettenkofer has ascertained that the product is greater if the cake be macerated in water for forty-eight hours before being submitted to distillation. (*Journ. de Pharm.*, Mai, 1862, p. 432.) It is sometimes produced in France from peach kernels.

Oil of bitter almond has a yellowish color, a bitter, acrid, burning taste, and the odor of the kernels in a high degree. It is heavier than water, soluble in alcohol and ether, according to Flückiger soluble in 300 parts of hot or cold water, and deposits, upon standing, a white crystalline substance consisting chiefly of benzoic acid. It is officially described as "a clear, colorless or yellowish, thin, and strongly refractive liquid, having a peculiar, aromatic odor, and a bitter and burning taste. Specific gravity, 1·060 to 1·070 at 15° C. (59° F.). Boiling point, about 180° C. (356° F.). Optically inactive. Soluble in 300 parts of water at 15° C. (59° F.), and in alcohol or ether in all proportions; also soluble in nitric acid at ordinary temperatures without the evolution of nitrous vapors. In the fresh state the Oil is neutral to litmus, but when kept for some time it assumes an acid reaction, due to the formation of benzoic acid. If 10 drops of the Oil, dissolved in a little alcohol, be shaken with a few drops of a strong solution of sodium hydrate, then with a little ferrous sulphate test-solution, and finally mixed with a slight excess of hydrochloric acid, a blue precipitate will be produced (presence of *hydrocyanic acid*). The presence of *artificial oil containing chlorinated products* may be detected in the following manner. Fold a small strip of filter paper in the form of a taper, saturate it with the Oil, and lay it into a small porcelain capsule. Set this capsule into a larger one,

and provide a large beaker to be inverted over the capsule containing the taper. Then, having moistened the inner surface of the beaker with distilled water, ignite the taper, immediately invert the beaker over the capsule, and allow the products of combustion to be absorbed by the water in the beaker. If the beaker be now rinsed with a little distilled water, and the liquid filtered, the filtrate should yield no turbidity with silver nitrate test-solution. If 5 C.c. of the Oil be vigorously shaken, in a flask, with 50 C.c. of a cold saturated solution of sodium bisulphite, and the mixture heated for a few minutes on a water-bath, the odor of the Oil should disappear, and a nearly clear solution be formed, without the separation of any oily drops on the surface of the liquid (absence of *most other volatile oils* and of *nitrobenzol*)." *U. S.* Besides a peculiar volatile oil, it contains also hydrocyanic acid, with a small proportion of benzoic acid, and of a concrete principle called *benzoin*, $C_{14}H_{12}O_2$. It may be obtained pure by agitating it strongly with calcium hydrate and a solution of ferrous chloride, submitting the mixture to distillation, and drying the oil which comes over by digestion with calcium chloride. Mr. George Whipple states that if crude oil be redistilled into a solution of silver nitrate, and again distilled from a fresh solution of the same salt, it is obtained entirely free from hydrocyanic acid, which reacts with the silver and remains behind as silver cyanide. (See *A. J. P.*, xxvi. 348.) Thus purified, it is colorless, but still retains its peculiar odor, with a burning, aromatic taste, and is destitute of those poisonous properties of the crude oil which are dependent on hydrocyanic acid. The odor of the oil of bitter almond has been erroneously ascribed to that acid, which, on examination, will be found to smell differently and more feebly. Like most other volatile oils, this may produce deleterious effects if taken very largely. Hippuric acid is found in the urine of animals to which it has been given freely. The sp. gr. of the crude oil varies from 1·052 to 1·082, and is said to be greater when the oil is distilled from salt water than when distilled by the ordinary mode. That of the purified oil is 1·060, and its boiling point 180° C. (356° F.). It is *benzoic aldehyde*, $C_6H_5.COH$, which is produced by the action of oxidizing agents upon *benzyl alcohol*, $C_6H_5.CH_2OH$, and yields itself, when oxidized, *benzoic acid*, $C_6H_5.COOH$. The benzoic acid which the oil of bitter almond deposits on standing does not pre-exist in it, but results from the absorption of oxygen, as just stated. The concrete substance above referred to by the name of *benzoin* is polymeric with the oil, crystallizable in colorless shining prisms, without smell or taste, fusible at 248° F., and volatilizable unchanged at a higher temperature. It is formed abundantly in the original impure oil by the reaction of alkalies, but cannot be produced in it when deprived of hydrocyanic acid.* For the volumetric estimation of hydrocyanic acid in bitter almond oil by Kremers and Schreiner, see *Pharm. Rev.*, 1896, 196.

Artificial benzoic aldehyde is now made from toluene, C_7H_8. By the action of chlorine upon the hot hydrocarbon, benzyl chloride, $C_6H_5CH_2Cl$, results, and this yields benzoic aldehyde on distillation with lead nitrate and water in an atmosphere of carbon dioxide gas. More generally, however, benzal chloride, $C_6H_5CHCl_2$, is taken, as this, when heated under pressure with water or sulphuric acid, readily yields the benzaldehyde. The product is purified by conversion into the acid sulphite compound. Lippmann and Hawliczek have made exhaustive researches on the identity of the artificial with the natural oil of bitter almond, and have found the two oils absolutely identical, physically as well as chemically. At the present time (1899) *benzaldehyde*, or synthetic oil of bitter almond, is very largely used, its chief advantages being uniformity of composition and absence of hydrocyanic acid. (See *Pharm. Rev.*, 1896, 196.) To prevent the formation of benzoic acid in oil of bitter almond, Schimmel & Co. recommend the addition of 10 per cent. of alcohol to the oil.

Zeller mentions, as characteristics of the official oil by which its genuineness and purity may be known, its peculiar odor and high specific gravity,† its ready solubility in sulphuric acid, with the production of a reddish-brown color, but without visible decomposition, the slow action of nitric acid, the slow and partial solution of iodine without further reaction, the want of action of potassium chromate upon it, and the production of crystals when it is dissolved in an alcoholic solution of potassa. (See *P. J. Tr.*, ix. 575.) Mr. Redwood states that a very small proportion of alcohol may be detected in the oil by the effervescence, with disengagement of nitrous vapors, which ensues when the oil thus contaminated is mixed with an equal volume of nitric acid of the sp. gr. 1·5. With pure oil no other effect is obvious than a slight

* *Nitrobenzol, Nitrobenzene, or Artificial Oil of Bitter Almond.* This substance, which was discovered by Mitscherlich, is treated of in PART II.

† Schimmel & Co. (*Semi-Annual Report*, April, 1893) state that an oil of high specific gravity should be carefully examined for benzo-nitrile, C_6H_5CN, which may form by condensation from benzaldehyde and hydrocyanic acid, and afterwards when distilled even *in vacuo* will decompose into the same components.

change of color. (*Ibid.*, xi. 486.) If sulphuric acid produce with the oil a bright-red instead of a brownish-red color, the oil has probably been distilled with salt water, in which case it is apt, according to Mr. Ferris, to deposit a blood-red matter, occasionally complained of by druggists. (*Ibid.*, 565.)

Mr. Wm. A. Tilden has found that the introduction of a little fused calcium chloride into purified oil of bitter almond contributes to its preservation, probably by the absorption of the last traces of water contained in it. Of two specimens of the oil, which had been set aside for two years, one without addition, the other containing a fragment of the fused chloride, the former was found filled with crystals of benzoic acid, and the latter was perfectly free from crystalline deposit and quite fluid. (*P. J. Tr.*, 2d ser., viii. 325, Dec. 1866.)

Prof. J. M. Maisch proposes the following mode of detecting nitrobenzene in adulterated oil of bitter almond. Dissolve half a drachm of the suspected oil in two or three drachms of alcohol, add fifteen grains of pure fused caustic potassa, heat for a few minutes so as to dissolve the potassa, reduce the liquid to one-third, and then set aside to cool. If the oil be pure, it will remain liquid; while if nitrobenzene be present, there will, after cooling, be a sediment of azoxybenzid indicating adulteration. (*A. J. P.*, 1857, 544.) R. Wagner proposes the sp. gr. of the two oils as a test,—that of the oil of bitter almond being from 1·060 to 1·070, while that of nitrobenzene is from 1·18 to 1·201, and a mixture will have a higher sp. gr. than the pure oil. This would lead to the suspicion of the presence of nitrobenzene, which may then be separated by agitation with sodium bisulphite. The almond oil will dissolve, while the nitrobenzene will float on the surface. (*Journ. de Pharm. et de Chim.*, Mai, 1868, 399.) The most reliable test is undoubtedly to add zinc dust and dilute acid, whereby any nitrobenzene is reduced to aniline, which can then be detected by the violet color produced when sodium hypochlorite or potassium bichromate is added. Dr. H. Hager's plan is as follows. After the addition of 10 drops of the *pure* oil to 10 C.c. of 45 per cent. alcohol, or to a mixture of 5 C.c. of 90 per cent. alcohol and 5 C.c. of water, on closing the test-tube with the finger and turning it twice upside down, the oil dissolves to a clear solution. If nitrobenzene, even as little as 1 per cent., be present, the oil of bitter almond will dissolve at once, but the nitrobenzene will separate, clouding the liquid at first, but soon collecting in very minute but easily recognizable droplets which float about in the liquid. After standing for a while, these droplets unite to larger drops, when they become still more evident to the eye. The temperature of the alcohol must not exceed 16° C. (60·8° F.); it is best to keep it between 10° and 15° C. (50° and 59° F.). Any sample of oil of bitter almond which dissolves on very gentle agitation at once to a clear liquid in 20 times its volume of 45 per cent. alcohol does not contain any nitrobenzene, since only traces of the latter are dissolved by that menstruum. Small quantities of nitrobenzene present (up to 3 per cent.) disappear after the mixture stands for some time, but they are always the cause of the milkiness or cloudiness of the solution at the moment of preparation. A short cloudiness even occurs with as small a quantity as ½ per cent. Since most other essential oils yield a cloudy solution with 45 per cent. alcohol, this test may also indicate the presence of foreign essential oils.

Hager's test may also be used quantitatively for the estimation of the amount of nitrobenzene present. Oil of bitter almond requires for solution 16 to 17 times its volume of 45 per cent. alcohol. 2 C.c. of the oil are agitated with 34 C.c. of the 45 per cent. alcohol, and the mixture set aside. After the lapse of a day, the nitrobenzene (all but a trace which remains in solution) will be found collected at the bottom. An important indication of the presence of a sophistication is the cloudiness produced at the first moment. (*N. R.*, Oct. 1880.)

Medical Properties and Uses. The unpurified volatile oil of bitter almond, which is the product directed by the Pharmacopœia, operates upon the system in a manner closely analogous to that of hydrocyanic acid. A single drop is sufficient to destroy a bird, and four drops have caused the death of a dog of middle size. The case of a man is recorded who died in ten minutes after taking two drachms (7·5 C.c.) of the oil. It might be substituted with advantage for medicinal hydrocyanic acid, if it always contained a uniform percentage of the acid, as the acid contained in the oil is much less liable to decomposition, remaining for several years unaltered, if the oil be preserved in well-stopped bottles. According to Schrader, 100 parts of the oil contain sufficient acid for the production of 22·5 parts of Prussian blue; but the proportion is not constant, varying, according to Mr. Groves, from 8 to 12·5 per cent. From one-fourth of a drop to a drop (0·016–0·06 C.c.) may be given for a dose, to be cautiously increased till some effect upon the system is observed. It may be administered in emulsion with gum arabic, loaf-sugar, and water. It has been employed externally, dissolved

in water in the proportion of one drop (0·06 C.c.) to a fluidounce (30 C.c.), in *prurigo senilis* and other cases of troublesome *itching*. To facilitate the solution in water, the oil may be previously dissolved in spirit. Oil of bitter almond is sometimes used to conceal the taste of cod-liver oil and of castor oil.

OLEUM AMYGDALÆ EXPRESSUM. U. S. (Br.) Expressed Oil of Almond.

(Ō'LĒ-ŬM Ą-MĬG'DĄ-LÆ ĘX-PRĔS'SŬM.)

"A fixed oil expressed from Bitter or Sweet Almond." *U. S.* "The oil expressed from the Bitter or Sweet Almond." *Br.*

Oleum Amygdalæ, *Br.;* Almond Oil; Oleum Amygdalæ Dulcis, *U. S.* 1860; Oleum Amygdalarum; Huile d'Amandes douces, Huile d'Amandes, *Fr.;* Mandelöl, *G.;* Olio di Mandorle, *It.;* Aceite de Almendras, *Sp.*

This oil is obtained equally pure from sweet and from bitter almonds. In its preparation, the almonds, having been deprived of a reddish-brown powder adhering to their surface, by being rubbed together in a piece of coarse linen, are ground in a mill resembling a coffee-mill, or bruised in a stone mortar, and then pressed in canvas sacks between plates of iron slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. Sometimes the almonds are steeped in very hot water, deprived of their cuticle, and dried in a stove, previous to expression. The oil is thus obtained free from color, but in no other respect better, while it is more apt to become rancid on keeping. Bitter almonds treated in this way impart a smell of hydrocyanic acid to the oil. M. Boullay obtained 54 per cent. of oil from sweet almonds, Vogel 28 per cent. from bitter almonds. Munch gives 55·4 per cent. as the yield of the former, and 52 per cent. as that of the latter. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 400.) These figures are not realized, however, in the ordinary expression methods. Schaedler (*Technologie der Fette und Oele*, 2te Auf., 532) gives 45 per cent. as the average obtained from the sweet almonds, and 38 per cent. from the bitter almonds. Though sometimes expressed in this country from imported almonds, the oil is generally brought from Europe.

Oil of almond is "a clear, pale straw-colored or colorless, oily liquid, almost inodorous, and having a mild, nutty taste. Specific gravity, 0·915 to 0·920 at 15° C. (59° F.). Only slightly soluble in alcohol; soluble in ether and in chloroform in all proportions. It remains clear at —10° C. (14° F.), and does not congeal until cooled to near —20° C. (—4° F.). If 2 C.c. of the Oil be vigorously shaken with 1 C.c. of fuming nitric acid and 1 C.c. of water, a whitish, not red or brownish, mixture should be formed, which, after standing for some hours at about 10° C. (50° F.), should separate into a solid, white mass, and a scarcely colored liquid (distinction from the fixed oils of *apricot* and *peach kernels*, and from *sesamum*, *cotton seed*, and *poppy seed oils*). If 10 C.c. of the oil be mixed with 15 C.c. of a 15 per cent. solution of sodium hydrate and 10 C.c. of alcohol, and the mixture allowed to stand at a temperature of 35° to 40° C. (95° to 104° F.), with occasional agitation, until it becomes clear, and then diluted with 100 C.c. of water, the clear solution thus obtained, upon the subsequent addition of an excess of hydrochloric acid, will set free a layer of oleic acid. This, when separated from the aqueous liquid, washed with warm water, and clarified in a water-bath, will remain liquid at 15° C. (59° F.), although sometimes depositing particles of solid matter and becoming turbid. One part of this oleic acid, when mixed with 1 volume of alcohol, should give a clear solution, which at 15° C. (59° F.) should not deposit any fatty acids, nor become turbid on the further addition of 1 volume of alcohol (distinction from *olive*, *arachis*, *cotton seed*, *sesamum*, and *other fixed oils*)." *U. S.* "Pale yellow, nearly inodorous, with a bland nutty taste. Soluble in *ether* and *chloroform* in all proportions. Specific gravity 0·915 to 0·920. It does not congeal until cooled to nearly —4° F. (—20° C.). If 2 cubic centimetres of the Oil be well shaken with 1 cubic centimetre of *fuming nitric acid* and 1 cubic centimetre of *water*, a whitish, not brownish-red, mixture should be formed, which after standing for 6 hours at about 50° F. (10° C.) should separate into a solid white mass and a nearly colorless liquid (absence of peach-kernel oil and other fixed oils)." *Br.* From the statement of Braconnot, it appears to contain 76 per cent. of olein and 24 per cent. of a mixture of palmitin and stearin.

According to Dr. H. Hager, the oils expressed from the large sweet and the smaller bitter almonds differ considerably, as shown by the elaidin test,—the former oil congealing more rapidly, and almost completely, the latter about twelve hours later, and the more imperfectly the smaller the bitter almond has been. Only about one-third of the bulk congeals when the oil is from the small Oporto almonds.

Oil of almond is said to be sometimes adulterated with poppy oil, or other drying oils of less

value. This sophistication may be detected, as suggested by M. Wimmec, by taking advantage of the property, belonging to the olein of the non-drying but not to that of the drying oils, of being converted into solid elaidic acid by the action of nitric acid. By treating iron filings with nitric acid in a flask, nitrous acid is produced, which is to be conducted into water upon which the suspected oil is placed. If the almond oil contain even a small quantity of poppy-seed oil, or other drying oil, this will remain in the form of drops on the surface, while the genuine oil will be converted entirely into crystallized elaidin. (*Journ. de Pharm.*, Dec. 1862, p. 500.) Colza oil, another not uncommon adulteration, may be detected, according to M. Schneider, by the action of silver nitrate. Dissolve the oil in twice its volume of ether, add about 30 drops of a concentrated alcoholic solution of the nitrate, shake the mixture, and allow it to stand in the dark. If there be much colza oil, the lower part of the liquid will become first brown and then black; if but little, the brown color will not appear for twelve hours; but the discoloration will always be obvious on the evaporation of the ether. (*P. J. Tr.*, March, 1862.)

It is said that in the south of France the sweet almond oil is sometimes adulterated with a cheaper oil, called *oil of apricots*. According to M. J. Nicklés, this adulteration may be detected by means of powdered calcium hydrate, which with the oil of apricots forms an emulsion that slowly assumes an unctuous consistence, while it has no such action on the almond oil, merely rendering it opaque for a time, and then gradually separating and leaving the oil clear. A mixture of the two oils emulsionizes with the lime, and on standing deposits the unctuous matter referred to. (See *A. J. P.*, 1866, p. 299.)

According to Dr. Hager, if equal volumes of the oil and of 25 per cent. nitric acid are shaken together in a test-tube, an emulsion-like mixture is produced, which separates on standing. All true almond oils yield a white mixture, and the oils remain white for many hours after separation, but the oils of *peach* and *apricot seeds* turn yellowish at once on being shaken with the acid, and the color afterwards deepens, and in half an hour is of a rather deep red-yellow. (*A. J. P.*, 1870, p. 408.) J. D. Bieber communicates the following test. Equal weights of pure concentrated sulphuric acid, red fuming nitric acid, and water are mixed, and the mixture allowed to cool. On mixing five parts of the oil with one part of this acid liquid, *pure almond oil* gives a yellowish-white liquid; *oil of peach kernels* assumes the red color of peach blossoms, turning to dark orange; *benne oil* turns pale yellowish red, then dirty orange-red; *poppy* and *walnut oils* yield a somewhat whiter liquid than almond oil. This test permits the detection of 5 per cent. of peach kernel and benne oil. Mixed with pure nitric acid, sp. gr. 1·40, *almond oil* yields a pale-yellowish liquid, *peach kernel oil* a red, *benne oil* a yellowish green, afterwards reddish, and *poppy* and *walnut oils* a white mixture. It was found that the oil expressed, cold or warm, from either fresh almonds or from such as had been kept up to ten years, gave the same reaction. Most of the commercial oil was found to be adulterated with the oil of either peach kernels or benne seed. (*A. J. P.*, Dec. 1877.)

Oil of almond may be used for the same purposes as is olive oil, and, when suspended in water by means of mucilage or the yolk of egg and loaf-sugar, forms a pleasant emulsion, useful in pulmonary affections attended with cough. From a fluidrachm to a fluidounce (3·75–30 C.c.) may be given at a dose.

OLEUM ANETHI. Br. Oil of Dill.

(Ō'LḘ-ŬM Ą-NĒ'THĪ.)

"The oil distilled from Dill Fruit." *Br.*

Aneth à Odeur forte, Essence d'Aneth, *Fr.;* Dill, Dillöl, *G.;* Aneto, *It.;* Eneldo, *Sp.*

Oil of dill is of a pale yellow color, with the odor of the fruit, and a hot, sweetish, acrid taste. Its sp. gr. varies between 0·895 and 0·915. The fruit yields about 3·5 per cent. of it. The oil is a mixture of limonene, phellandrene, and a paraffin hydrocarbon along with *carvol*, $C_{10}H_{14}O$. "Color pale yellow, odor that of the fruit, taste sweet and aromatic. Specific gravity 0·905 to 0·920. It rotates the plane of a ray of polarized light not less than 70° to the right, at 60° F. (15·5° C.), in a tube 100 millimetres long." *Br.* R. Nietski obtained from the fruit of *Anethum graveolens* a volatile oil, which commenced to boil at 155° C. (311° F.), the boiling point rising gradually to 260° C. (500° F.). About 10 per cent. of the oil consists of a hydrocarbon, $C_{10}O_{16}$, having the boiling point from 155°–160° C., 60 per cent. boiling at from 170°–175° C. (338°–347° F.), of the same composition, and 30 per cent. with the boiling point from 225°–230° C. (437°–446° F.), composition $C_{10}H_{14}O$, and identical with carvol. The odor of the first portion of hydrocarbon is similar to that of turpentine; that of the second portion resembles oil of mace, but when mixed with a little carvol the characteristic dill odor is

at once produced. (*A. J. P.*, 1874.) The oil is sometimes used for preparing dill water. Dose, from three to ten drops (0·18–0·6 C.c).

OLEUM ANISI. U. S., Br. Oil of Anise.

(Ō'LḘ-ŬM Ą-NĪ'SĪ.)

Essence d'Anis, *Fr.;* Anisöl, *G.*

"A volatile oil distilled from Anise. It should be kept in well-stoppered bottles protected from light, and, if it has separated into a liquid and a solid portion, it should be completely liquefied by warming before being dispensed." *U. S.* "The oil distilled from Anise Fruit; or from the fruit of the star-anise, Illicium verum, Hook. fil." *Br.*

The product of oil from anise is variously stated at from 1·56 to 3·12 per cent. The oil employed in this country is imported. It is colorless or yellowish, with the peculiar odor and taste of the seed. At 50° F. it crystallizes in flat tables, and it does not melt under 62° F. Its sp. gr. increases with age, and is variously given at from 0·9768 to 0·9903. It is soluble in all proportions in alcohol of 0·806; but alcohol of 0·840 dissolves at 77° only 42 per cent. Ether dissolves it in all proportions. (Gmelin.) "A colorless or pale yellow, thin, and strongly refractive liquid, having the characteristic odor of anise, and a sweetish, mildly aromatic taste. Specific gravity, about 0·980 to 0·990 at 17° C. (62·6° F.), increasing with age. At a low temperature, usually between 10° and 15° C. (50°–59° F.), it solidifies to a white, crystalline mass. Soluble in an equal volume of alcohol to a clear solution (absence of *most fixed oils* and of *oil of turpentine*). This solution is neutral to litmus paper, and should not assume a blue or brownish color on the addition of a drop of ferric chloride test-solution (absence of some *volatile oils containing phenols*). When the Oil is dropped into water, without agitation, it should not produce a milky turbidity (absence of *alcohol*)." *U. S.* "Colorless or pale yellow; with the odor of the fruit, and a mildly aromatic taste. It congeals, when stirred, at temperatures between 50° and 59° F. (10° to 15° C.), and should not again become liquid below 59° F. (15° C.). Specific gravity at 68° F. (20° C.) 0·975 to 0·990. It rotates the plane of a ray of polarized light slightly to the left." *Br.* It consists of a small quantity of a hydrocarbon, $C_{10}H_{16}$, but mainly of *anethol*, $C_{10}H_{12}O$, which is present, however, in two isomeric modifications, one solid at ordinary temperatures and heavier than water (*solid anethol*), the other liquid and more volatile (*methyl chavicol*). *Anethol*, both in the liquid and in the solid form, is present, and is the chief constituent of the oils of *anise*, *star aniseed*, and *fennel*. By oxidation, by means of nitric or chromic acid, the different forms of anethol* yield *anisic acid*, $C_8H_8O_3$. Oil of anise absorbs oxygen from the air, and becomes less disposed to concrete. In consequence of its high price, it is frequently adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odor. In one instance as much as 35 per cent. of spermaceti was found. Schimmel & Co. have found fennel stearoptene in commercial oil of anise. (*Pharm. Rev.*, 1897, 94.) Prof. Procter met with a parcel, of which not less than five-sixths were alcohol. (*A. J. P.*, xxvii. 513.) The dose of the oil is from five to fifteen drops (0·3–0·9 C.c.) Its comparative mildness adapts it to infantile cases. Most of the oil of anise of commerce is the *oil of star aniseed* (*Oleum Badiani*, or *Oleum Illicii*). Oil of anise has also been distilled from the sweet cicely, *Osmorhiza longistylis*, of the United States and Canada. (*Pharm. Rundschau*, July, 1887.) For description and analysis of Russian oil of anise, see *P. J. Tr.*, 1896, 164, also 243. Anisic acid is said to be antiseptic, resembling salicylic acid in its action.

OLEUM ANTHEMIDIS. Br. Oil of Chamomile.

(Ō'LḘ-ŬM ĄN-THḔM'Į-DĬS.)

"The oil distilled from chamomile flowers." *Br.*

Oleum Chamomillæ Romanæ; Essence de Camomille romaine, *Fr.;* Römisch-Kamillenöl, *G.*

This oil was introduced into the British Pharmacopœia 1885 with the direction that it should be distilled in Britain. No such restriction is found in the Pharmacopœia of 1898. It is seldom prepared in this country. Baumé obtained thirteen drachms of the oil from eighty-two pounds of the flowers; according to Mr. Brande, the average product of 100 pounds is two pounds twelve ounces. It has the peculiar smell of chamomile, with a pungent somewhat aromatic taste. When recently distilled it is of a pale sky-blue or greenish-blue color, which changes to yellow or brownish on exposure. "Specific gravity 0·905 to 0·915." *Br.* The

* For an account of the numerous isomers of anethol, see Orndorff, Terrasse, and Morton, *Amer. Chem. Journ.*, 19, 845.

oil was thoroughly investigated in Fittig's laboratory during the years 1878–79. It was found to consist of a mixture of *angelic* and *tiglinic esters of isobutyl*, *isamyl*, *hexyl*, and probably one higher one. Angelic acid and tiglinic acid are isomeric, and have the formula $C_5H_8O_2$. The relative proportions of these two acids varied in different oils. It has sometimes been employed in spasm of the stomach, and as an adjunct to purgative medicines. Its chief use, however, appears to be as an ingredient of the extract of chamomile of the British Pharmacopœia, to which it is added in order to supply the place of the oil driven off by the heat used in its preparation. This oil must not be confounded with that of *Matricaria chamomilla*, employed on the continent of Europe under the name of oil of chamomile. (See *Matricaria.*) The dose is from five to fifteen drops (0·3–0·9 C.c.).

OLEUM AURANTII CORTICIS. U. S. Oil of Orange Peel.

(Ō'LḘ-ŬM ÂU-RĂN'TI-Ī CÖR'TI-CĪS.)

"A volatile oil obtained by expression from the fresh peel of either the Bitter Orange, Citrus vulgaris, Risso, or the Sweet Orange, Citrus Aurantium, Linné (nat. ord. Rutaceæ). It should be kept in well-stoppered bottles, in a cool place." *U. S.*

Essential Oil of Orange Peel; Huile d'Orange, *Fr.;* Apfelsinenschalenöl, Pomeranzenschalenöl, *G.*

This oil is used only for flavoring purposes, and has been introduced principally because of its employment in elixirs and in *Spiritus Aurantii* and *Spiritus Aurantii Compositum.* Oil of orange is prepared in Calabria and Sicily in three ways: 1, by scraping off the exterior part of the rind and submitting it to expression; 2, by putting the scrapings into hot water, depressing the pulp beneath, and skimming off the oil as it rises; 3, by distillation. The best Sicily orange oil is procured by dexterous compression, within a cask, of the fresh rind by the hand, the oil being driven out in jets. It is sometimes absorbed by a sponge. (*A. J. P.*, 1868.) It is largely made at Messina, and in the south of France. It is also extracted by the écuelle process,* and partly from the Bigarade and partly from the sweet or Portugal orange, the scarcely ripe fruit being in either case employed. The oil made from the former is much more valuable than that obtained from the latter, and the two are distinguished in price-currents as *Essence de Bigarade* and *Essence de Portugal.*

Properties. Oil of orange peel yields on distillation, besides a resinous product of the composition $C_{20}H_{30}O_3$, a hydrocarbon, *hesperidene*, $C_{10}H_{16}$ (Wright and Piesse, *Chem. News*, xxiv. 147), boiling at 178° C. (352·4° F.). The inner thick part of the rind contains also a bitter principle, called *hesperidin*, discovered by Lebreton in 1828, but more fully studied by Hoffmann (*Ber. Chem. Ges.*, 1876, pp. 26, 685). It is best prepared from the unripe bitter orange. Its formula is $C_{22}H_{26}O_{12}$, and it is a glucoside, as is shown by the reaction with dilute sulphuric acid, whereby it is decomposed into *hesperetin*, $C_{16}H_{14}O_6$, and glucose, $C_6H_{12}O_6$.

The U. S. Pharmacopœia describes the oil as "a pale yellowish liquid, having the characteristic, aromatic odor of orange, and an aromatic and, when obtained from the bitter orange, somewhat bitter taste. Specific gravity, about 0·850 at 15° C. (59° F.). Its optical rotation should not be less than 95° to the right in a 100 Mm. tube, and at a temperature of about 15° to 20° C. (59° to 68° F.). Soluble in about four times its volume of alcohol, this solution being neutral to litmus paper; also soluble, in all proportions, in absolute alcohol or in carbon disulphide, and in an equal volume of glacial acetic acid. When kept for some time, the Oil should not develop a terebinthinate odor or taste (absence of *oil of turpentine* or of *other oils containing pinene*)." *U. S.* This oil is one of the most difficult to preserve. A method for its preservation, which we have used for years, is to shake the oil briskly with one-eighth of its volume of distilled water, and allow it to separate, then remove the essential oil, filter rapidly if necessary, and mix the filtered oil with 95 per cent. alcohol in the proportion of one volume of the oil to seven volumes of alcohol.

OLEUM AURANTII FLORUM. U. S. Oil of Orange Flowers. [Oil of Neroli.]

(Ō'LḘ-ŬM ÂU-RĂN'TI-Ī FLŌ'RŬM.)

"A volatile oil distilled from the fresh flowers of the Bitter Orange, Citrus vulgaris, Risso (nat. ord. Rutaceæ). It should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.*

Huile de Fleurs d'Orange, Essence de Néroli, *Fr.;* Pomeranzenblüthenöl, *G.*

* For an illustration of the écuelle, see Remington's *Practice of Pharmacy*, p. 789.

This official oil is employed only on account of its pleasant odor and taste, and is largely used as an ingredient in Cologne water, perfumes, etc. The best quality of "oil of neroli," as it is universally called in commerce, comes from Nice, and is derived from the flowers of the *Citrus aurantium*, or sweet orange, by distillation with water; this is called "*néroli pétale.*" The next quality is obtained in the same way, but by using the blossoms of the *Citrus Bigaradia*, or bitter orange: this is called "*néroli bigarade;*" whilst an inferior sort, "*essence de petit grain,*" is made by distilling the leaves and unripe fruit. This should not be classed with "neroli," as it is unworthy of the name. *Oil of Petit Grain Citronnier* is a fragrant oil, distilled from the leaves and twigs of the lemon-tree; it closely resembles the essence de petit grain from the orange leaves and fruit. (*Chem. and Drug.*, 1897, 53.)

Properties. It is officially described as "a yellowish or brownish, thin liquid, having a very fragrant odor of orange flowers, and an aromatic, somewhat bitter taste. Specific gravity, 0·875 to 0·890 at 15° C. (59° F.). Soluble in an equal volume of alcohol, the solution being neutral to litmus paper. If a little alcohol be poured on the surface of the Oil, and the mixture gently undulated, a bright, violet fluorescence will usually be observed. In contact with a saturated solution of sodium bisulphite it assumes a handsome and permanent purplish-red color." *U. S.* The greater part of the oil is a hydrocarbon, distilling at from 185°–195° C. (365°–383° F.), with which is a small amount of a crystalline solid called *neroli camphor.** According to Flückiger, this is a neutral, inodorous, tasteless substance, fusing at 55° C. (131° F.). According to Semmler (*Ber. der Chem. Gesell.*, 26, 2711), the oil contains about 20 per cent. of limonene, 30 per cent. of linalool, $C_{10}H_{18}O$; 40 per cent. of linaloyl acetate, and 3 per cent. of geraniol. *Schimmel & Co.'s Report*, April, 1897 mentions a small amount of a paraffin as also present. Noel distinguishes the different volatile oils of the orange tribe by shaking five drops of the oil with one C.c. of pure concentrated hydrochloric acid. After one minute seven or eight C.c. of 90 per cent. alcohol are added, whereby the color is changed, and increased or decreased according to the extent of the adulteration. It is obvious that to use effectually such a test requires special education. (See *Proc. A. P. A.*, 1887.)

OLEUM BERGAMOTTÆ. U. S. Oil of Bergamot. [Oleum Bergamii, Pharm. 1880.]

(Ō'LĒ-ŬM BĔR-GĄ-MŎT'TÆ.)

"A volatile oil obtained by expression from the rind of the fresh fruit of Citrus Bergamia, Risso et Poiteau (nat. ord. Rutaceæ). It should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.*

Oleum Bergamottæ, *P. G.;* Essence de Bergamotte, Huile de Bergamotte, *Fr.;* Bergamottöl, *G.;* Olio di Bergamotta, *It.*

CITRUS. See *Aurantii Cortex.*

Citrus bergamia. Risso & Poiteau. *B. & T.* 52.—*C. limetta.* De Cand. *Prodrom.* i. 539. The bergamot-tree has oblong-ovate, dentate, acute, or obtuse leaves, somewhat paler on the under than on the upper surface, and with footstalks more or less winged or margined. The flowers are white, and usually small; the fruit pyriform or roundish, about three inches in diameter, terminated by an obtuse point, with concave receptacles of oil in the rind. The pulp of the fruit is sourish, somewhat aromatic, and not disagreeable. The rind is shining, and of a pale-yellow color, and abounds in a very grateful volatile oil. This may be obtained by expression or distillation. In the former case it preserves the agreeable flavor of the rind, but is somewhat turbid; in the latter it is limpid but less sweet. The mode of procuring it by expression is exactly the same as that used for oil of lemon. (See *Oleum Limonis.*) It is brought from Italy, the south of France, and Portugal.

The oil of bergamot, often called *essence of bergamot*, has a sweet, very agreeable odor, a bitter, aromatic, pungent taste, a pale greenish-yellow color, and a slightly acid reaction. Its sp. gr. varies from 0·870 to 0·888. (*Lewis, Zeller.*) "Specific gravity, 0·880 to 0·885 at 15° C. (59° F.). Its optical rotation should not be more than 20° to the right in a 100 Mm. tube, and at a temperature of about 15° to 20° C. (59° to 68° F.). Two volumes of the Oil, when mixed with 1 volume of alcohol, should give a clear solution of a slightly acid reaction, and this solution should not become turbid on the further addition of alcohol (distinction from *oil*

* Under the name of *nerolin* an artificial product has been placed upon the market in the form of a white crystalline powder, soluble in alcohol and fixed oils and almost insoluble in water. It is used by soap-makers as a substitute for oil of neroli, and is said to be ten times as strong. This compound is said to be the ethyl ether of β-naphtol. (*Ber. der Chem. Ges.*, 1893, 2706.) It is also used in the manufacture of eau-de-Cologne with advantage instead of neroli oil. (Schimmel & Co., *Semi-Annual Report*, April, 1893.)

of orange or *oil of lemon*). The Oil should also be soluble at 20° C. (68° F.), without the separation of oily drops, in 1·5 to 2 volumes of alcohol of 80 per cent. by volume. It is soluble, in all proportions, in glacial acetic acid. If about 2 Gm. of the Oil be evaporated in a small, tared capsule, on a water-bath, until the odor has completely disappeared, a soft, green, homogeneous residue should be left, amounting to not more than about 6 per cent. of the Oil (absence of *fatty oils*)." *U. S.* It contains limonene, dipentene, linalool, a solid greasy compound called *bergaptene*, or *bergamot camphor*, and *linalool acetate*, $C_{10}H_{17}.C_2H_3O_2$, which latter makes up about 40 per cent. of the expressed oil, but is decomposed in large part by the process of steam distillation. Bergaptene has been very fully studied by Pomeranz. (*Monatsheft für Chem.*, 1891, 379.) It melts at 188° C., and has the composition $C_{12}H_8O_4$, being the lactone or inner anhydride of *bergaptenic acid*, $C_{12}H_{10}O_5$. By fusion with caustic potash, bergaptene yields phloroglucin. (See *Schimmel's Report*, April, 1893, and 1895, 24; also *Proc. A. P. A.*, 1897, 630.) The oil is distinguished from lemon and orange oils by readily dissolving in solution of potassa and forming with it a clear solution. (Zeller.) Though possessed of the excitant properties of the volatile oils in general, it is employed chiefly, if not exclusively, as a perfume.

OLEUM BETULÆ VOLATILE. U. S. Volatile Oil of Betula.

[Oil of Sweet Birch.]

(Ō'LḘ-ŬM BĔT'Ů-LÆ VŌ-LĂT'Ị-LĒ.)

"A volatile oil obtained by distillation from the bark of Betula lenta, Linné (Sweet Birch; nat. ord. Betulaceæ). It is identical with Methyl Salicylate [$CH_3C_7H_5O_3$], and nearly identical with Oil of Gaultheria. It should be kept in well-stoppered bottles, protected from light." *U. S.*

The *Betula lenta*, *cherry birch*, *sweet birch*, *black birch*, *mountain mahogany*, is a large American tree resembling in its dark, chestnut-brown bark, the general shape of its leaves, and its whole appearance the garden cherry. It grows northward from New England to Ohio and southward in the Blue Ridge as far as South Carolina and Georgia. It is especially characterized by its heart-ovate, pointed, sharply and finely doubly serrate leaves, and short petioles. The underneath veins of the leaves are hairy, as are also the elliptical, thick, fruity catkins, the lobes of whose venous scales are nearly equal, obtuse, and diverging.

In commerce the oil of birch is chiefly sold as the oil of wintergreen. It is very largely distilled by the mountaineers or small farmers, many of whom put indiscriminately into their stills the wintergreen and the bark of the birch, or at least mix the products before selling. Whilst in general use under the name of oil of gaultheria, it differs from the latter in not containing a terpene; its specific gravity is 1·17, whilst, according to Pettigrew, that of oil of gaultheria is 1·0318. For a description of the apparatus used to distil oil of birch, see *A. J. P.*, 1882, 49. It does not differ essentially from that described later in connection with oil of gaultheria. The so-called "light oil" of distillers, according to Mr. Kennedy, is simply the oil with water and dirt. Oil of sweet birch has the same properties and conforms to the same reactions and tests as does methyl salicylate. (See *Methyl Salicylas*; also *Oleum Gaultheriæ*.) So far as our present knowledge goes, oil of birch does not differ in its physiological and remedial properties from oil of gaultheria. Dose, from five to thirty minims (0·3–1·8 C.c.).

OLEUM CADINUM. U. S., Br. Oil of Cade. [Oleum Juniperi Empyreumaticum.]

(Ō'LḘ-ŬM CĄ-DĪ'NŬM.)

"A product of the dry distillation of the wood of Juniperus Oxycedrus, Linné (nat. ord. Coniferæ)." *U. S.* "An empyreumatic oily liquid obtained by the destructive distillation of the woody portions of Juniperus Oxycedrus, Linn., and some other species." *Br.*

Juniper Tar Oil; Huile de Cade, *Fr.*

The *Juniperus oxycedrus*, Linné, *prickly cedar*, or *large brown-fruited juniper*, is a common tree in the waste places and stony hill-sides of the Mediterranean districts of Northern Africa, Spain, Portugal, and France, reaching up in its distribution as high as 3000 feet in the Apennines. It commonly attains a height of from ten to twelve feet, sometimes much more, with long spreading branches and slender drooping branchlets, covered with light-green scattered and spreading leaves of medium size, lanceolate or awl-shaped, sharply pointed, having two furrows on their upper edge. The fruits are numerous, large (half an inch in diameter), globular, shining, reddish or chestnut-brown, and marked on the apex with two white lines.

From the heart-wood of this tree the oil of cade is prepared by a process of distillation in

ovens *per descensum*, similar to that practised in the making of ordinary tar. It is a brownish or dark brown liquid, much more mobile and less thick than tar, having a tar-like but distinct odor, and a smoky, acrid, bitterish, disagreeable taste. In mass it is dark and opaque, but in very thin layers clear; the oil contains phenols and a sesquiterpene termed *cadinene*, $C_{15}H_{24}$, the latter boiling at from 274° to 275° C. "Specific gravity, about 0·990 at 15° C. (59° F.). It is almost insoluble in water, but imparts to it an acid reaction. It is only partially soluble in alcohol, but is completely soluble in ether, chloroform, or carbon disulphide." *U. S.* The British Pharmacopœia describes it as "A dark reddish-brown or nearly black, more or less viscid, oily liquid, with a not unpleasant empyreumatic odor and an aromatic bitter and acrid taste. Specific gravity about 0·990. It is soluble in *ether* and *chloroform;* partially soluble in cold, almost wholly in hot *alcohol* (90 per cent.). It is very slightly soluble in *water*. The filtered aqueous solution is almost colorless and possesses an acid reaction." Yaucher recommends acetone for disguising the odor of oil of cade, and proposes an *oil of cade collodion* in which acetone is used to dissolve the pyroxylin instead of the usual solvents. (*Chem. and Drug.*, 1897, 16.)

Medical Properties and Uses. Oil of cade has been used by the peasantry in the treatment of the cutaneous diseases of sheep, horses, and other domestic animals almost from time immemorial. More recently it has been largely employed in the treatment of *chronic eczema*, *psoriasis*, and other skin diseases of man, and has also been found to be an efficient parasiticide in *psora* and *favus*. It is applied, sometimes of full strength, sometimes diluted with a bland oil, well rubbed into the affected parts with the fingers, or with a cloth, and is also made into ointments, and especially into soaps.* A glycerite is also prepared.

OLEUM CAJUPUTI. U. S., Br. Oil of Cajuput.

(Ō'LE-ŬM CĂJ-U-PŪ'TĪ.)

"A volatile oil distilled from the leaves of Melaleuca Leucadendron, Linné (nat. ord. Myrtaceæ). It should be kept in well-stoppered bottles, in a cool place." *U. S.* "The oil distilled from the leaves of Melaleuca Leucadendron, Linn. (Melaleuca Cajuputi, Roxb.)." *Br.*

Oleum Cajeputi, *P. G.;* Essence de Cajeput, Huile de Cajeput, *Fr.;* Cajeputöl, *G.;* Olio di Cajeput, *It.;* Kayuputieh, *Mal.*

Gen. Ch. Calyx five-parted, semi-superior. *Corolla* five-petalled. *Stamens* about forty-five, very long, conjoined in five bodies. *Style* single. *Capsule* three-celled. *Seeds* numerous. *Roxburgh.*

It was long supposed that the oil of cajuput was derived from *Melaleuca leucadendron;* but from specimens of the plant affording it, sent from the Moluccas and cultivated in the botanical garden of Calcutta, Roxburgh concluded it to be a distinct species, and gave it the name of *M. cajuputi*. It corresponds with the *arbor alba minor* of Rumphius, and is a smaller plant than the *M. leucadendron*. Bentham, however, probably with correctness, considers it simply a smaller variety of *M. leucadendron*, a tree of wide-spread habitat, reaching into India, the Philippines, and even Australia. It is possible, however, that the oil may be obtained from different species of Melaleuca, as M. Stickel, of Jena, succeeded in procuring from the leaves of *M. hypericifolia*, cultivated in the botanical garden of that place, a specimen of oil not distinguishable from the cajuput oil of commerce, except by a pale-green color. (*Annal. der Pharm.*, xix. 224.) *M. viridifolia* and *M. latifolia*, large trees growing abundantly in the island of New Caledonia, yield a volatile oil very analogous to the oil of cajuput.† The leaves of

* In the *Edinb. Monthly Journ.* for July, 1852 (page 66), it is stated that the soap is made by distilling the tar, incorporating the volatile oil obtained with a fixed oil, and then saponifying this with soda. It is in the form of black balls, readily unites with water, and may be applied to the surface like any other soap. The best plan is probably to apply it at bedtime and wash it off next morning.

† It seems to be uncertain how much of the oil of cajuput of commerce is produced by the New Caledonia trees. In the *Bull. Thérap.*, xcvii., the volatile oil of *Melaleuca flaviflora* is said to be sent in large quantities, under the name of *miaouli*, from New Caledonia to the East. More recently a pale-yellow oil occurring in French commerce under the name of *essence de miaouli* is reported to be obtained by distillation of the leaves of the *Melaleuca viridiflora*, which yield of it about 2·5 per cent. This oil has been carefully studied by G. Bertrand, who describes it as having a density of 0·922 and deviating a ray of polarized light 0° 42′ to the right. He finds that it contains minute quantities of amylic alcohol, but is chiefly composed of a dextro-rotatory terebinthene, $C_{10}H_{16}$, eucalyptol, a hydrocarbon (probably citrene) boiling at 175° F., and a terpinol. This composition is identical with that of the terpinol of List (*Comptes-Rendus*, civ. 996, cvi. 663), obtained by heating with acidulated water the terpene, $C_{10}H_{16}$,-$2H_2O$, resulting from the spontaneous hydration of terpene, $C_{10}H_{16}$, the natural product being thus readily imitated artificially in the laboratory by extremely simple reactions. (*Comptes-Rendus*, cxvi. 1070.) This oil has been used in doses of from ten to fifty centigrammes daily, in capsules, by Dr. Blanc, for the purposes for which oil of cajuput is usually employed. (*Revue de Thérap.*, lx.)

different species of Melaleuca have been used advantageously, in the form of bath, in chronic rheumatism. (*Annuaire de Thérap.*, 1861, p. 67.) An extract of *M. paraguayensis* has been used with alleged advantage in rheumatism and other diseases. (*Med. Record*, xvi.)

Melaleuca leucadendron. Linné. *Cajuputi.* Rumphius, *Herbar. Amboinense*, tom. ii. tab. 17; Roxburgh, *Trans. Lond. Med. Bot. Soc.*, 1829; *Journ. of the Phila. Coll. of Pharm.*, vol. i. p. 193. —*M. minor.* De Candolle. *B. & T.* 108. This tree grows with an erect but crooked stem, and scattered branches, the slender twigs of which droop like those of the weeping willow. The bark is of a whitish ash color, very thick, soft, spongy, and lamellated, throwing off its exterior layer from time to time in flakes. The leaves have short footstalks, are alternate, lanceolate, when young sericeous, when full-grown smooth, deep green, three- and five-nerved, slightly falcate, entire, from three to five inches long, from one-half to three-quarters of an inch broad, and when bruised exhale a strong aromatic odor. The flowers are small, white, inodorous, sessile, and disposed in terminal and axillary downy spikes, with solitary, lanceolate, three-flowered bracts. The filaments are three or four times longer than the petals, and both are inserted in the rim of the calyx. The oil is obtained from the leaves by distillation. It is prepared chiefly in Amboyna and Bouro, and is exported from the East Indies in glass bottles. The small proportion yielded by the leaves, and the extensive use made of it in India, render it costly.

Properties. Cajuput oil is very fluid, transparent, of a fine green color, a lively and penetrating odor analogous to that of camphor and cardamom, and a warm, pungent taste. It is very volatile and inflammable, burning without any residue. The sp. gr. varies from 0·914 to 0·9274. Its composition, according to Blanchet and Sell, is $C_{10}H_{18}O$, and by repeated distillation over phosphoric oxide the hydrocarbon, $C_{10}H_{16}$, called *cajuputene*, can be obtained. The oil is, therefore, said to contain *cajuputene hydrate*, or *cajuputol*. The identity of cajuputol with cineol and eucalyptol from *Eucalyptus globulus* in both chemical and physical properties has been established by C. Jahns. (*A. J. P.*, 1885, 237.) It boils at 175° C. (347° F.). *Schimmel & Co.'s Report*, April, 1897 states as additional constituents terpineol, terpenyl acetate, and probably valeraldehyde, benzaldehyde, and pinene. Oil of cajuput is "a light, thin, bluish-green, or, after rectification, colorless liquid, having a peculiar, agreeable, distinctly camphoraceous odor, and an aromatic, bitterish taste. Specific gravity, 0·922 to 0·929 at 15° C. (59° F.). With an equal volume of alcohol it affords a clear solution, which either has a slightly acid reaction, or, in the case of the rectified Oil, is neutral to litmus paper. On shaking 5 C.c. of the Oil with 5 C.c. of water containing a drop of diluted hydrochloric acid, the Oil loses its green tint and becomes nearly colorless. If to this acid liquid, separated from the Oil, a drop of potassium ferrocyanide test solution be added, a reddish brown color will usually be produced (presence of traces of *copper*). If 5 parts of the Oil be heated to 50° C. (122° F.), and 1 part of powdered iodine gradually added, with avoidance of any further rise of temperature, the mixture, on cooling, will deposit a mass of crystals." *U. S.* "Bluish green, with an agreeable penetrating camphoraceous odor, and an aromatic bitterish camphoraceous taste. Specific gravity from 0·922 to 0·930. It should become semi-solid on being stirred, when cold, with a third or half its volume of phosphoric acid of commerce of specific gravity 1·750 (presence of a due proportion of cineol)." *Br.* The oil is wholly soluble in alcohol. When it is distilled, a light, colorless liquid first comes over, and afterwards a green and denser one. The green color has been ascribed to a salt of copper derived from the vessels in which the distillation is performed; and Guibourt obtained two grains and a half of copper oxide from a pound of the commercial oil. But neither Brande nor Goertner could detect copper in specimens examined by them; and M. Lesson, who witnessed the process for preparing the oil at Bouro, attributes its color to chlorophyll or some analogous principle, and states that it is rendered colorless by rectification. Guibourt, moreover, obtained a green oil by distilling the leaves of a Melaleuca cultivated at Paris. A fair inference is that the oil of cajuput is naturally green, but that as found in commerce it sometimes contains copper, either accidentally present or added with a view of imitating or maintaining the fine color of the oil. The proportion of copper, however, is not so great as to forbid the internal use of the oil; and the metal may be separated by distillation with water, or by agitation with a solution of potassium ferrocyanide. This statement as to the frequent occurrence of copper in the cajuput oil of commerce, though at the same time its presence is not essential, has been confirmed by experiments by Mr. Edward Histed, who found copper in all of six specimens of the commercial oil, obtained from different sources. When redistilled, the oil became perfectly colorless, but after a few days' exposure to copper filings reassumed its green color. (*P. J. Tr.*, 1872, p. 804.)

The high price of cajuput oil has led to its occasional adulteration. Oil of rosemary, and oil

of turpentine, impregnated with camphor and colored with the resin of milfoil, are said to be employed for the purpose. The best test, according to Zeller, is iodine, which, after a moderately energetic reaction, with little increase of temperature and but a slight development of orange vapors, occasions immediate inspissation into a loose coagulum, which soon becomes a dry, greenish-brown, brittle mass.

Medical Properties and Uses. This oil is highly stimulant, producing when swallowed a sense of heat, with an increased fulness and frequency of pulse, and exciting in some instances profuse perspiration. It is much esteemed by the Malays and other people of the East, who consider it a panacea. The complaints to which it is best adapted are probably *chronic rheumatism*, and *spasmodic affections of the stomach and bowels*, unconnected with inflammation. It has been extolled as a remedy in *spasmodic cholera*, and has been used also as a diffusible stimulant in *low fevers*. It is said to have been used in the collapsed state of cholera, with unexpected success, in the dose of from fifteen grains to a drachm (1–3·9 Gm.) in a single potion. (*Ann. de Thérap.*, 1867, p. 71.) Diluted with an equal proportion of olive oil, it is applied externally to relieve *gouty* and *rheumatic pains*. Like most other highly stimulating essential oils, it relieves *toothache* if introduced into the hollow of the carious tooth. M. Delvaux, who has made extensive use of this oil, has found it beneficial, given internally, in *dyspepsia* with flatulence, in the early stages and milder forms of *cholera*, in *verminose affections* in children, in *chronic laryngitis* and *bronchitis*, in *chronic catarrh of the bladder*, in *chronic rheumatism of the joints* with little or no swelling, and in painful *chronic rheumatism of the muscles and fibro-muscular tissues*, whether external or internal. Externally applied, M. Delvaux has derived great benefit from it in various cutaneous diseases, as *pityriasis*, *psoriasis*, and especially in that extremely obstinate affection of the face, *acne rosacea*, which he has often succeeded in curing by the simple application of this oil three times a day. (*Annuaire de Thérap.*, 1862, p. 38.) The dose is from five to twenty drops (0·3–1·25 C.c.), given in emulsion, in the form of pill, or upon a lump of sugar.

OLEUM CARI. U. S. (Br.) Oil of Caraway.

(Ō'LĒ-ŬM CĀ'RĪ.)

"A volatile oil distilled from Caraway." *U. S.* "The Oil distilled from caraway fruit." *Br.*

Oleum Carui, *Br.*; **Oleum Carvi**, *P. G.*; **Essence de Carvi**, *Fr.*; **Kümmelöl**, *G.*

This oil is prepared to a considerable extent by our distillers. The fresh fruit as cultivated in Holland yields nearly 6 per cent. of oil, while the German fruit yields about 4 per cent. The oil of caraway is somewhat viscid, of a pale-yellow color, becoming brownish by age, with the odor of the fruit, and an aromatic acrid taste. Its sp. gr. is differently given at 0·946 (*Baumé*), 0·931 (*Brande*), 0·916 (*Buignet*), and 0·920 (*U. S. P.*). It is dextrogyrate in its relation to polarized light. (Buignet, *Journ. de Pharm.*, Oct. 1861, p. 261.) It consists of two liquid oils, of different boiling points, and separable by distillation,—one a hydrocarbon called *carvene* ($C_{10}H_{16}$), of the sp. gr. 0·849 and boiling point 176° C. (349° F.), now recognized as identical with limonene, the other, *carvol*, $C_{10}H_{14}O$, of the sp. gr. 0·9638 and boiling point 224° C. (435° F.). This latter constituent is often extracted from the oil and prepared in a pure state by taking advantage of the formation of a crystalline compound of carvol and hydrogen sulphide, which can then be decomposed by treatment with alcoholic potash.

It is officially described as "a colorless, or pale yellow, thin liquid, having the characteristic, aromatic odor of caraway, and a mild, spicy taste. Specific gravity, 0·910 to 0·920 at 15° C. (59° F.). Soluble in an equal volume of alcohol, this solution being neutral to litmus paper." *U. S.* "Colorless or pale yellow, with the characteristic odor of the fruit, and a spicy taste. Specific gravity 0·910 to 0·920." *Br.* For additional tests, see *Schimmel & Co.'s Report*, 1893, 10; also *Bull. Pharm.*, 1894, 257.

When oil of caraway is distilled over glacial phosphoric acid or powdered caustic soda, the distilled liquor being poured back into the retort until it ceases to have the smell of caraway, an oily liquid is obtained, having a very disagreeable odor, and a strong taste. This product, to which the name of *carvacrol* has been applied, has been found to give immediate relief to *toothache*, when inserted on cotton into the cavity of a carious tooth. (See *Am. Journ. of Med. Sci.*, N. S., xv. 532.) Carvacrol is found to be of the same chemical composition as carvol, and is considered to be formed from it by molecular rearrangement merely. Oil of caraway is much used to impart flavor to medicines, and to correct their nauseating and griping effects. The dose is from one to ten drops (0·06–0·6 C.c.).

OLEUM CARYOPHYLLI. U. S., Br. Oil of Cloves.

(Ō-LĒ-ŬM CĂR-Y-Ō-PHĬL'LĪ.)

"A volatile oil distilled from Cloves." *U. S.* "The Oil distilled from cloves." *Br.*

Oleum Caryophyllorum, *P. G.;* Essence de Girofles, *Fr.;* Nelkenöl, *G.*

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebullition; and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. Professor Scharling has found advantage from the application of superheated steam to the distillation of this oil. (*P. J. Tr.*, xi. 469.) It is essential also to use the same water over and over again, in order to avoid loss by the solution of the oil in the water. The product of good cloves is said to be about one-fifth or one-sixth of their weight. The oil was formerly brought from Holland or the East Indies; but since the introduction of the Cayenne cloves into our markets the reduced price and superior freshness of the drug have rendered the distillation of oil of cloves profitable in this country; and the best now sold is of domestic extraction. We have been informed that from seven to nine pounds of cloves yield to our distillers about one pound of the oil.

Properties. Oil of cloves, when recently distilled, is very fluid, clear, and colorless, but becomes yellowish by exposure, and ultimately reddish brown. It has the odor of cloves, a hot, acrid, aromatic taste, and a slightly acid reaction. Its sp. gr. is variously stated at from 1·034 to 1·061,—the latter being given by Bonastre as the sp. gr. of the rectified oil. "Specific gravity, 1·060 to 1·067 at 15° C. (59° F.). Soluble in an equal volume of alcohol, this solution being slightly acid to litmus paper; also soluble in an equal volume of glacial acetic acid. When shaken with an equal volume of a concentrated solution of potassium hydrate, or of stronger ammonia water, it forms a semi-solid, yellowish mass. If two drops of the Oil be dissolved in 4 C.c. of alcohol, and a drop of ferric chloride test-solution added, a bright green color will be produced; and if the same test be made with a drop of dilute ferric chloride test-solution, prepared by diluting the test-solution with four times its volume of water, a blue color will be produced, which soon changes to yellow. If 1 C.c. of the Oil be mixed with 2 C.c. of a mixture of 2 volumes of alcohol and 1 volume of water, it should form a clear and perfect solution (absence of *petroleum*, *most fatty oils*, *oil of turpentine*, and *similar oils*). If 1 C.c. of the Oil be shaken with 20 C.c. of hot water, the water should show a scarcely perceptible acid reaction to litmus paper. If, after cooling, the aqueous layer be passed through a wet filter, the clear filtrate should yield, with a drop of ferric chloride test-solution, only a transient grayish-green, but not a blue or violet color (absence of *carbolic acid*)." *U. S.* "Colorless or pale yellow when recent, but gradually becoming reddish-brown, having the strong odor and taste of cloves. Specific gravity not below 1·050. An alcoholic solution yields a blue color with *test-solution of ferric chloride*. Shaken with its own volume of *strong solution of ammonia* it forms a semi-solid yellowish mass." *Br.* It is one of the least volatile of the essential oils, and requires for congelation a temperature from zero of Fahrenheit to —4°. It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its color to a deep red, and converts it by the aid of heat into oxalic acid. The same change to red is produced by nitric acid on morphine, but in this case the red is followed by yellow, which does not happen with the oil of cloves. Besides, if to a solution of morphine with nitric acid a solution of chlorinated lime be added, and the mixture be exposed for some hours to the light, the solution of morphine will retain a straw color, while if oil of cloves be treated in the same manner the color disappears. (Haselden, *B. and F. Med.-Chir. Rev.*, July, 1867, 265.) When long kept, the oil deposits a crystalline *stearopten*. It is frequently adulterated with fixed oils, and sometimes with oil of pimenta and with copaiba. When pure, it sinks in distilled water. According to E. Scherer, these adulterations may sometimes be detected by attention to the specific gravity and the boiling point, pure oil of cloves varying in specific gravity from 1·03 to 1·06, and boiling at from 240° C. (464° F.) to 255° C. (491° F.). According to Zeller, its character of congealing entirely into a crystalline mass with the alcoholic solution of potassa, losing at the same time its peculiar odor, affords a sufficient criterion of its purity. It appears to be indifferent in its rotatory effects on polarized light. (Buignet.)

Oil of cloves contains small amounts of *methyl alcohol* and *furfurol*, but is mainly composed of an unsaturated phenol termed *eugenol* and a sesquiterpene *caryophyllene*. Eugenol, $C_{10}H_{12}O_2$, has been shown to be the methyl ether of allyl-dioxybenzene, $C_6H_3\begin{cases}C_3H_5\\OCH_3\\OH\end{cases}$. One of its most important reactions is its conversion into *vanillin*. For this purpose it is boiled

with acetic anhydride, whereby *aceteugenol* is formed, which, oxidized in weak acid solution by potassium permanganate, yields *acetvanillic acid*, and this with weak potash solution is changed into vanillin, which is then extracted by acidifying and shaking up with ether. (See also *Pharm. Era*, 1887, 444.) For the estimation of eugenol in the form of its crystalline benzoyl compound, see *A. J. P.*, 1892, 26 and 508; also *Schimmel & Co.'s Report*, April, 1892, 28. The characteristic aromatic odor of oil of cloves is due to *methyl-amylketone*, ($CH_3(CH_2)_4CO.CH_3$), which has been isolated by the chemists of Schimmel & Co., and found to be present only in minute quantity. (*Pharm. Rev.*, 1897, 115.)

Medical Properties and Uses. The medical effects of the oil are similar to those of cloves, and it is used for the same purposes; but its most common employment is as a corrigent of other medicines. It is a powerful local narcotic, and is often introduced into the cavity of a *carious aching tooth*. The dose is from two to six drops (0·12 to 0·36 C.c.). *Eugenol* has been given internally in doses of forty-five grains per day dissolved in alcohol and diluted in water; it probably resembles carbolic acid in its physiological actions, and has been used as an antiseptic and antipyretic. According to the experiments of Dr. Leubuscher (*Wien. Med. Blätter*, 1889), it is a feeble local anæsthetic.

OLEUM CHENOPODII. U. S. Oil of Chenopodium. [Oil of American Wormseed.]

(Ō'LḘ-ŬM ȹHĒN-Ọ-PŌ'DḮ-Ī.)

"A volatile oil distilled from Chenopodium." *U. S.*

Essence de Chénopode anthelmintique, *Fr.;* Amerikanisches Wurmsamenöl, *G.*

This oil is peculiar to the United States. It is prepared in the vicinity of Baltimore. (See page 367.) It is of a light-yellow color when recently distilled, but becomes deeper yellow and even brownish by age. Its reaction is neutral. It has in a high degree the peculiar flavor of the plant. "Specific gravity, about 0·970 at 15° C. (59° F.). 1 C.c. of the oil should form a perfectly clear solution with 10 C.c. of a mixture of 3 volumes of alcohol and 1 volume of water." *U. S.* When freshly prepared, it has the sp. gr. 0·908, which, according to Mr. S. S. Garrigues, is increased by time to 0·960. A portion examined by him, which was of a brownish-yellow color, had the sp. gr. 0·959 at 61° F., boiled at 374° F., and was freely soluble in alcohol and ether. He found it to be composed of two distinct oils, separable by distillation: one of these has the formula $C_{10}H_{16}$, and reacts with hydrochloric acid in a manner analogous to oil of turpentine; the other is heavier, and possesses the formula $C_{10}H_{16}O$. (*A. J. P.*, xxvi. 405.) Wormseed oil is used as an anthelmintic, in the dose of from four to eight drops (0·24–0·5 C.c.) for a child, repeated morning and evening for three or four days, and then followed by a brisk cathartic. The case of a child, six years old, is recorded (*Boston Med. and Surg. Journ.*, xlv. 373) in which death is supposed to have resulted from the use of overdoses.

OLEUM CINNAMOMI. U. S., Br. Oil of Cinnamon. [Oil of Cassia.]

(Ō'LḘ-ŬM CĬN-NẠ-MŌ'MĪ.)

"A volatile oil distilled from Cassia Cinnamon. It should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.* "The oil distilled from Cinnamon Bark." *Br.*

Oleum Cinnamomi Zeylanici, *P. G.;* Oil of Ceylon Cinnamon, *E.;* Essence de Cannelle, Huile de Cannelle, *Fr.;* Zimmtöl, Zeylonisches Zimmtöl, *G.;* Olio di Cannella, *It.;* Aceite de Canela, *Sp.*

There are two oils of cinnamon in commerce,—one procured from the Ceylon cinnamon, the other from the Chinese cinnamon, and often distinguished by the name of *oil of cassia*. There is no essential difference in the two oils; and that of the Chinese cinnamon, as much the cheaper and more abundant of the two, will probably continue to be generally employed, notwithstanding that the Ceylon product has the finer flavor.*

Oil of cinnamon of Ceylon is prepared in that island from inferior kinds of cinnamon, of insufficient value to pay the export duty. The following account of the method of extraction is given by Marshall. The bark, having been coarsely powdered, is macerated for two days in sea-water, and then submitted to distillation. A light and a heavy oil come over with the

* Schimmel & Co. (*Semi-Annual Report*, April, 1892) have shown that *cinnamon-leaf oil* (from *Cinnamomum zeylanicum*), instead of being a thick, viscid oil, as frequently stated, is a bright, limpid oil, and is identical with the oil formerly exported from Ceylon in large quantities and thought to be produced from the roots of the cinnamon shrub. It has a sp. gr. of 1·05 to 1·06, and contains about 87 per cent. of eugenol and about 0·1 per cent. of cinnamic aldehyde: from this composition the cloves and cinnamon-like odor which it possesses may be understood. Safrol is also present in small amounts. Dr. von Romburgh (Schimmel & Co., *Report*, Oct. 1892) has prepared the true cinnamon-root oil, and finds it to contain large amounts of camphor, to which its odor is obviously due.

water, the former of which separates in a few hours and floats upon the surface, the latter falls to the bottom of the receiver, and continues to be deposited for ten or twelve days. In future distillations, the saturated cinnamon water is employed with sea-water to macerate the cinnamon. Eighty pounds of the freshly prepared bark yield about 2·5 ounces of the lighter oil, and 5·5 of the heavier. From the same quantity kept for several years in store, about half an ounce less of each oil is obtained. The two kinds are probably united in the oil of commerce. The oil is also distilled in Ceylon from the leaves, but the product is said to be too small to yield a fair profit. (*Chem. and Drug.*, 1888.)

Recently prepared oil of Ceylon cinnamon is of a light-yellow color, becoming deeper by age, and ultimately red. Pereira states that the London druggists redistil the red oil, and thus obtain two pale-yellow oils, one lighter and the other heavier than water, with a loss of about 10 per cent. in the process. The oil has the flavor of cinnamon, and when undiluted is excessively hot and pungent. It is said sometimes to have a peppery taste, ascribable to an admixture of the leaves with the bark in the preparation of the oil. *Oil of Ceylon Cinnamon* has "a slightly acid reaction. Sp. gr. about 1·040. It is readily soluble in alcohol. When cooled to —10° C. (14° F.), it remains clear, but at a lower temperature a solid portion separates from it." *U. S.* 1880. The British Pharmacopœia 1898 recognizes oil of Ceylon cinnamon only, and gives the following description and tests: "Yellow when freshly distilled, but gradually becoming reddish; having the odor and taste of the bark. Specific gravity 1·025 to 1·035. 1 cubic centimetre dissolved in 5 cubic centimetres of *alcohol* (90 per cent.), and *test-solution of ferric chloride* added, should afford a pale green, but not a decided blue coloration (absence of cinnamon-leaf oil). If 10 cubic centimetres be well shaken with 50 cubic centimetres of a boiling 30 per cent. solution of *sodium hydrogen sulphite*, an oily layer separates, which, when cooled to 60° F. (15·5° C.), should not measure more than 5 cubic centimetres (absence of more than 50 per cent. of constituents other than aldehydes)."

Chinese oil of cinnamon is imported from Canton and Singapore. It is pale yellow, becoming red with age. Its flavor is similar to that of the Ceylon oil, though inferior; and it commands a much lower price. It is officially described as "a yellowish or brownish liquid, becoming darker and thicker by age and exposure to the air, having the characteristic odor of cinnamon, and a sweetish, spicy, and burning taste. Specific gravity, 1·055 to 1·065 at 15° C. (59° F.). Soluble in an equal volume of alcohol, the solution being slightly acid to litmus paper; also soluble in an equal volume of glacial acetic acid. When shaken with a saturated solution of sodium bisulphite, it solidifies to a crystalline mass. If 4 drops of the Oil, contained in a test-tube, be cooled to 0° C. (32° F.), and then shaken with 4 drops of fuming nitric acid, crystalline needles or plates will be formed. If a portion of the Oil be shaken with water, and the liquid passed through a wet filter, the clear filtrate should give, with a few drops of basic lead acetate test-solution, a white turbidity, without a yellow color (absence of *oil of cloves*). If 4 drops of the Oil be dissolved in 10 C.c. of alcohol, the subsequent addition of a drop of ferric chloride test-solution should produce a brown, but not a green or blue, color (absence of *oil of cloves* or of *carbolic acid*). If 1 C.c. of the Oil be mixed with 3 C.c. of a mixture of 3 volumes of alcohol and 1 volume of water, a clear solution should result; and if to this solution there be gradually added 2 C.c. of a saturated solution of lead acetate in a mixture of 3 volumes of alcohol and 1 volume of water, no precipitate should be produced (absence of *petroleum*, or of *colophony*)." *U. S.* The researches of Schimmel & Co. seem to show that the Chinese cassia oil of commerce is distilled out of the leaves, leaf-stalks, and young twigs of the cassia plant,—probably with broken bark and various refuse products from the tree; also that much of the oil is adulterated with rosin and petroleum. (See official tests above.)* Zeller states that it is heavier, less liquid, and sooner rendered turbid by cold, and that in the Ceylon oil iodine dissolves rapidly, with a considerable increase of heat, and the production of a tough residue, like extract, while in oil of cassia the reaction is slow, quiet, and with little heat, and the residue is soft or liquid. The following remarks apply to both.

Alcohol completely dissolves oil of cinnamon; and, as it does not rise in any considerable

* The value of cassia oil is stated to depend upon the percentage of cinnamic aldehyde which it contains. In a series of analyses made by Schimmel & Co. of oils having a specific gravity of 1·064 to 1·065, the proportion of aldehyde varied from 73·5 to 88 per cent. In the distillation by Schimmel & Co. the various portions of the cassia plant obtained from China yielded the following result. 1. Cassia bark, *Cassia lignea* of commerce: yield of essential oil 1·5 per cent.; aldehyde in oil 88·9 per cent.: sp. gr. 1·035. 2. Cassia buds, *Flores Cassiæ* of commerce: yield of essential oil 1·550 per cent.: aldehyde in oil 80·4 per cent.: sp. gr. 1·026. 3. Cassia budsticks: yield of essential oil 1·64 per cent.: aldehyde in oil 92 per cent.: sp. gr. 1·046. 4. Cassia Leaves, leaf-stalks, and young twigs mixed: yield of essential oil 0·77 per cent.; aldehyde in oil 93 per cent.; sp. gr. 1·055.

quantity at the boiling temperature of that liquid, it may be obtained by forming a tincture of cinnamon and distilling off the menstruum. When exposed to the air, it absorbs oxygen, and is slowly converted into cinnamic acid, two distinct resins, and water. Of the two resins, one is soluble both in hot and in cold alcohol; the other readily in the former, but sparingly in the latter. *Cinnamic acid*, $C_9H_8O_2$, is colorless, crystalline, sourish, volatilizable, slightly soluble in water, readily dissolved by alcohol, and convertible by nitric acid with heat into benzoic acid. It is sometimes seen in crystals in oil of cinnamon which has been long kept. Like benzoic acid, it is said when swallowed to cause the elimination of hippuric acid by the urine. (*Journ. de Pharm.*, 3e sér., iii. 64.) It may be obtained by distilling the balsam of Tolu. Oil of cinnamon is almost wholly converted by nitric acid, slowly added, into a crystalline mass, thought to be a compound of the oil and the acid. These several facts are explained when it is found that oil of cinnamon contains from 75 to 90 per cent. of *cinnamic aldehyde*, C_9H_8O, which by moderate oxidation yields the corresponding cinnamic acid, $C_9H_8O_2$, but by more energetic oxidation yields benzoic acid, $C_7H_6O_2$. The oil has been produced artificially by Strecker from styrone, a derivative from styrax (see *Styrax*), and more recently from benzaldehyde and acetaldehyde, a mixture of which is saturated with hydrochloric acid gas, when a condensation takes place, as follows: $C_6H_5COH + CH_3COH = C_6H_5CH = CH.CHO + H_2O$. Ordinary sodium hydrate will also bring about the reaction between the two aldehydes, and is to be preferred to hydrochloric acid for this purpose. The only other constituent of the cassia oil is cinnamyl acetate. Ceylon cinnamon oil, on the other hand, is said to contain some eugenol and phellandrene in addition to the cinnamic aldehyde. Kebler recommends the estimation of cinnamic aldehyde volumetrically. (See *A. J. P.*, 1896, 193.)

Oil of cinnamon is said to be frequently adulterated with oil of cloves, which, according to Ulex, cannot be detected by the smell or taste. Thus sophisticated, it is stated, on the same authority, to evolve a very acrid vapor when a drop is heated on a watch-glass, to swell up and evolve red vapors if treated with fuming nitric acid, to remain liquid with concentrated caustic potassa, and to assume an indigo-blue color when ferrous chloride is added to its alcoholic solution; none of which reactions occur with pure oil. (*Archiv der Pharm.*, Jan. 1853.)

Medical Properties and Uses. This oil has the cordial and carminative properties of cinnamon, without its astringency, and is much employed as an adjuvant to other medicines, the taste of which it corrects or conceals, while it conciliates the stomach. As a powerful local stimulant, it is sometimes prescribed in *gastrodynia*, *flatulent colic*, and *gastric debility*. The dose is from one to three drops (0·06–0·18 C.c.). Mitscherlich found six drachms to kill a moderate-sized dog in five hours, and two drachms one in forty hours. Inflammation and corrosion of the gastro-intestinal mucous membrane were observed after death.

OLEUM COPAIBÆ. U. S., Br. Oil of Copaiba.

(Ō'LĒ-ŬM CŌ-PĀ'I-BÆ.)

"A volatile oil distilled from Copaiba." *U. S.* "The oil distilled from copaiba." *Br.*

Oil of Copaiva; Oleum Balsami Copaivæ; Essence de Copahu, *Fr.*; Copaibaöl, *G.*

The oil constitutes from one-third to one-half or more of the copaiba. From one specimen of recent copaiba as much as 80 per cent. has been obtained. (*A. J. P.*, xxii. 289.) It is prepared largely in Philadelphia by the application of steam heat. As it first comes over it is colorless, but the later product is of a fine greenish hue. By redistillation it may be rendered wholly colorless. It has the odor and taste of copaiba, a neutral reaction, boils at 252°–256° C. (485·6°–492·8° F.), solidifies, partly crystalline, at —15° F. (*Gmelin*), is soluble in ether and in an equal weight of alcohol. Oil of copaiba consists chiefly of *caryophyllene*, $C_{15}H_{24}$. "A colorless or pale yellowish liquid, having the characteristic odor of copaiba, and an aromatic, bitterish, and pungent taste. Specific gravity, 0·890 to 0·910 at 15° C. (59° F.), increasing with age. Soluble in about 10 times its volume of alcohol, forming a slightly turbid liquid, which is neutral to litmus paper." *U. S.* "Colorless or pale yellow, with the odor and taste of copaiba. Specific gravity 0·900 to 0·910. It turns the plane of a ray of polarized light to the left, and is soluble in its own volume of *absolute alcohol* (distinction from African copaiba oil)." *Br.* From its want of oxygen, it answers even better than naphtha for preserving potassium, a fact first observed by Mr. Durand, of Philadelphia. It dissolves sulphur and phosphorus. (*Gmelin's Handbook*, xiv. 288.)

Its effects on the system are those of copaiba. From the experiments of C. Mitscherlich, it is one of the least injurious of the volatile oils to the animal system, six drachms of it having been introduced into the stomach of a rabbit without causing death. Externally it

produces much less irritation than does oil of turpentine. It may be used for the same purposes as copaiba, in the dose of from ten to fifteen drops (0·6–0·9 C.c.), given in emulsion or dropped on sugar.

OLEUM CORIANDRI. U. S., Br. Oil of Coriander.

(Ō'LḘ-ŬM CŌ-RḬ-ĂN'DRĪ.)

"A volatile oil distilled from Coriander." *U. S.* "The oil distilled from coriander fruit." *Br.*

Essence de Coriandre, *Fr.;* Korianderöl, *G.*

This is obtained by distillation with water from the bruised seeds in the manner directed in the U. S. Pharm. 1870 for the other volatile oils. Forty-two grains of it are stated by Zeller to be derived from a pound of the fruit. It is pale yellow and colorless, and has the characteristic smell and taste of coriander, and a neutral reaction. Its sp. gr. is from 0·870 to 0·885, *U. S.*, and its boiling point 302° F. It is an oxygenated oil, consisting chiefly of a compound, *coriandrol*, $C_{10}H_{18}O$. According to Semmler (*Ber. der Chem. Ges.*, 24, 206), coriandrol boils between 194° and 198° C., is optically dextro-rotatory, and has a sp. gr. of 0·8679 at 20° C. Coriandrol is now known as *linalool*. Schimmel & Co. (*Report*, April, 1892) have also found in coriander oil about 5 per cent. of dextro-pinene. "One C.c. of the Oil forms a perfectly clear solution with 3 C.c. of a mixture of 3 volumes of alcohol and 1 volume of water, the solution being neutral to litmus paper. The Oil is also soluble in an equal volume of glacial acetic acid." *U. S.* "Colorless or pale yellow, having the odor and flavor of the fruit. Specific gravity 0·870 to 0·885. If 1 cubic centimetre of the Oil be mixed with 3 cubic centimetres of *alcohol* (70 per cent.), a clear solution results (absence of oil of turpentine and added terpenes)." *Br.* Oil of coriander is extensively adulterated with colorless rectified oil of orange, which can be detected by its insolubility in 90 per cent. alcohol, in which pure coriander oil dissolves in every proportion; equal parts of oil of orange and 90 per cent. alcohol make a turbid mixture. (*A. J. P.*, Sept. 1878.) The oil has the medical properties of the fruit, and, like the aromatic oils generally, may be used to cover the taste or correct the nauseating or griping properties of other medicines. It has the great advantage of being more stable and retaining its agreeable odor longer than any other oil of its class.

OLEUM CUBEBÆ. U. S., Br. Oil of Cubeb.

(Ō'LḘ-ŬM CŪ-BĒ'BÆ.)

"A volatile oil distilled from Cubeb." *U. S.* "The oil distilled from Cubebs." *Br.*

Oleum Cubebarum; Oil of Cubebs; Essence de Cubèbes, *Fr.;* Kubebenöl, *G.*

The oil is obtained from cubeb by grinding the berries, and then distilling with water. From ten pounds Schönwald procured eleven ounces of oil; and this result very nearly coincides with the experiments of Christison, who obtained 7 per cent. When recently distilled from the fruit, the oil is somewhat greenish, becoming yellowish by age; but when carefully redistilled it is colorless. It has the smell of cubeb, a warm, aromatic, camphorous taste, and a neutral reaction, is of a consistence approaching that of almond oil, is lighter than water, having the sp. gr. 0·920 (0·910–0·930, Br. Ph.), and when exposed to the air is said to thicken without losing its odor. It is soluble in an equal weight of alcohol. The oil consists chiefly of *cadinene*, $C_{15}H_{24}$, with some *dipentene*. Upon standing, it sometimes deposits rhomboidal prismatic crystals of a stearopten. This camphor of cubeb has the formula $C_{15}H_{26}O$, is fusible at from 66° to 68° C., and volatilizes without change at from 148° to 150° C. According to Schmidt, it does not pre-exist in the cubeb, but is formed by the prolonged action of the air. (*Journ. de Pharm.*, Juin, 1875.) The oil has the aromatic properties of cubeb; but it is probably not the sole active ingredient, as it is much less pungent than the fluid extract or the oleoresin. It may, however, often be advantageously substituted for the powder, in the commencing dose of ten or twelve drops (0·6 or 0·72 C.c.), to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, or in the form of emulsion, or enclosed in capsules of gelatin.

OLEUM ERIGERONTIS. U. S. Oil of Erigeron. [Oil of Fleabane.]

(Ō'LḘ-ŬM Ḛ-RĬÇ-Ḛ-RŎN'TĮS.)

"A volatile oil distilled from the fresh, flowering herb of Erigeron Canadense, Linné (nat. ord. Compositæ)." *U. S.*

Oleum Erigerontis Canadensis, *U. S.* 1870; Oil of Canada Fleabane.

Oil of erigeron is limpid, of a light straw color, a peculiar aromatic persistent odor, and a characteristic taste. By exposure it becomes darker and thicker. Its reaction is neutral. Its sp. gr. is about 0·850, increasing with age (0·855 to 0·890, Schimmel & Co.). It consists chiefly of dextrogyrate limonene, together with some terpineol. (*A. J. P.*, 1893, 420.) "Soluble in an equal volume of alcohol (distinction from *oil of fireweed* (derived from *Erechthites hieracifolia* Rafinesque, nat. ord. *Compositæ*) and from *oil of turpentine*), this solution being neutral or slightly acid to litmus; also soluble in an equal volume of glacial acetic acid. It distils for the most part between 175° and 180° C. (347° and 356° F.)." *U. S.* When distilled without water, it comes over colorless, and a little resinous matter is left behind, probably resulting from the oxidation of one or both of the constituent oils. It is readily soluble in alcohol. It consists of carbon, hydrogen, and oxygen. It is slowly reddened by potassa, combines with iodine without explosion, is instantly decomposed by sulphuric acid, and is acted on by strong nitric acid, slowly at ordinary temperatures, but with heat explosively. (Procter, *A. J. P.*, xxvi. 502.) For an account of the difference in properties between this oil and that from *Erechthites hieracifolia*, see a paper by Albert M. Todd, *A. J. P.*, 1887, p. 302.

It was first brought into notice by the so-called eclectic physicians, who use it in *diarrhœa*, *dysentery*, and the *hemorrhages;* and certainly it is a very valuable remedy in *hæmoptysis* when there is no fever or other marked evidence of constitutional irritation. As long ago as 1854 it was commended highly by Dr. E. Wilson in *uterine hemorrhage*, while Dr. J. W. Moorman speaks of it most highly in all forms of hemorrhage, in *diarrhœa of debility*, in *dysentery* after sufficient evacuation of the stomach and bowels, and especially in *hemorrhage from the bowels during typhoid fever*. (*Am. Journ. of Med. Sci.*, Oct. 1865, p. 396.) It probably acts like the oil of turpentine as a hæmostatic, but is much less irritant and stimulating. Dose, from ten minims to half a fluidrachm (0·6–0·18 C.c.), repeated every hour or two.

OLEUM EUCALYPTI. U. S., Br. Oil of Eucalyptus.

(Ō'LḘ-ŬM EŪ-CA-LĬP'TĪ.)

"A volatile oil distilled from the fresh leaves of Eucalyptus globulus, Labillardière, Eucalyptus oleosa, F. v. Mueller, and some other species of Eucalyptus (nat. ord. Myrtaceæ)." *U. S.* "The oil distilled from the fresh leaves of Eucalyptus Globulus, Labill., and other species of Eucalyptus." *Br.*

Essence d'Eucalyptus, *Fr.;* Eucalyptusöl, *G.*

Various species of the genus Eucalyptus, grown in Australia and Algeria, yield a volatile oil in sufficient quantity to be a commercial product. Probably the most important of these plants are the *E. amygdalina*, whose volatile oil was at one time supposed to be destitute of eucalyptol, but has been shown by Gildemeister (*Pharm. Zeitung*, 1888) to contain that principle, but to have phellandrene * for its chief constituent; *E. odorata*, the oil of which is affirmed to be extremely rich in eucalyptol, but to contain no phellandrene; and *E. oleosa*, the oil of which is stated to be so rich in eucalyptol that at a low temperature it becomes pasty. Under these circumstances the revisers of the U. S. Pharm. acted very properly in rejecting all those oils which contain enough of phellandrene to respond to the sodium nitrite test. Oil of eucalyptus is officially described as "a colorless or faintly yellowish liquid, having a characteristic, aromatic, somewhat camphoraceous odor, and a pungent, spicy, and cooling taste. Specific gravity, 0·915 to 0·925 at 15° C. (59° F.). Soluble, in all proportions, in alcohol, carbon disulphide, or glacial acetic acid. Its alcoholic solution is neutral, or slightly acid, to litmus paper. If 1 C.c. of the Oil be mixed with 2 C.c. of glacial acetic acid, and 1 or 2 C.c. of a saturated aqueous solution of sodium nitrite be gradually added, the mixture, when gently stirred, should not form a crystalline mass (distinction from *oils of Eucalyptus containing a considerable proportion of phellandrene*)." *U. S.* "Specific gravity 0·910 to 0·930. It should not rotate the plane of a ray of polarized light more than 10° in either direction in a tube 100 millimetres long, and it should become semi-solid on being stirred, when cold, with a third or half its volume of phosphoric acid of commerce of specific gravity 1·750 (presence of a due proportion of cineol). If to 1 cubic centimetre of the Oil there be added 2 cubic centimetres of *glacial acetic acid* and 2 cubic centimetres of a saturated aqueous solution of *sodium nitrite*, the mixture, when gently stirred, should not form a crystalline mass (exclusion of eucalyptus oils containing much phellandrene)." *Br.* Power has modified the test for phellandrene so as to make it more delicate. According to his directions, 1 C.c. of the oil is mixed with 5 C.c. of petroleum benzin,

* Phellandrene (see *Olea Volatilia*, p. 905) is one of two members of the terpane group which forms solid nitrosites with nitrous acid, the other being terpinene.

1 or 2 C.c. of a concentrated solution of sodium nitrite added, and subsequently glacial acetic acid added, a drop or two at a time, with vigorous agitation after each addition. If phellandrene be present in any considerable amount, its crystalline nitrosite, $C_{10}H_{16}(NO)NO_2$, will separate from the benzin solution. It contains *cymene*, $C_{10}H_{14}$, *pinene*, $C_{10}H_{16}$, and *eucalyptol* (or *cineol*), $C_{10}H_{18}O$. Schimmel & Co. also state (*Bericht*, April, 1888) that they have obtained several of the aldehydes of the fatty series, notably *valeraldehyde*, and probably *butyraldehyde* and *capronaldehyde*, in their distillation of the oil from *Eucalyptus globulus*. The medical value of the oil of eucalyptus has been believed to depend upon the eucalyptol present in it, but we have no definite knowledge as to the physiological action of phellandrene, and it may well be that the phellandrene oils act similarly to the eucalyptol. As eucalyptol is now official, it may be preferred by the practitioner as being of definite strength and character, the percentage of eucalyptol even in the best oils varying considerably. The dose is from ten to fifteen minims (0·6–0·9 C.c.); best administered in capsules.

OLEUM FŒNICULI. U. S. Oil of Fennel.

(Ō′LḘ-ŬM FŒ-NĬC′Ů-LĪ.)

"A volatile oil distilled from Fennel. It should be kept in well-stoppered bottles, in a cool place, and, if it has partly or wholly solidified, it should be completely liquefied by warming before being dispensed." *U. S.*

Essence de Fenouil, *Fr.*; Fenchelöl, *G.*

Fennel seeds yield about 2·5 per cent., or, according to Zeller, from 3·4 to 3·8 per cent., of oil. That used in this country is imported. It is colorless or yellowish, with a neutral reaction, and the odor and taste of the seeds. "Specific gravity, not less than 0·960 at 15° C. (59° F.). Between 5° and 10° C. (41° and 50° F.) it usually solidifies to a crystalline mass, but occasionally it remains liquid at a considerably lower temperature. Soluble in an equal volume of alcohol, the solution being neutral to litmus paper; also soluble in an equal volume of glacial acetic acid. The Oil is not colored by the addition of a drop of ferric chloride test-solution (absence of some foreign oils containing *phenols*, and of *carbolic acid*). If the Oil be dropped into water, without agitation, it should not produce a milky turbidity (absence of *alcohol*)." *U. S.* It congeals below 50° F. into a crystalline mass, separable by pressure into a solid and a liquid portion, the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. It contains *pinene*, *phellandrene*, *dipentene*, *fenchone*, $C_{10}H_{16}O$, and *anethol*, $C_{10}H_{12}O$, the latter usually in amounts of about 60 per cent. (*Power's Catalogue of Essential Oils*, 1894.) *Schimmel's Report* for April, 1897, mentions *limonene* as also at times present as a constituent. Umney finds that Japanese oil contains about 75 per cent. of anethol and 10 per cent. of fenchone, besides terpenes. (*Proc. A. P. A.*, 1897. 516.) There is reason to believe that much of the commercial oil is adulterated with oil from which the anethol or crystalline constituent has been separated; the official solidifying point (from 5° to 10° C.) should be required. Flückiger states (*Pharm. Chem.*, 2d ed., 1888, 422) that it contains more hydrocarbon than oil of anise, and notably that from Nîmes, in Southern France, contains much less anethol, and hence has a milder and sweeter taste. As found in the shops, therefore, the oil of fennel is not uniform; and a specimen examined by Dr. Montgomery did not congeal at 22° F. (See *Oleum Anisi.*) It is slightly dextrogyrate. The dose is from five to fifteen drops (0·3–0·9 C.c.).

OLEUM GAULTHERIÆ. U. S. Oil of Gaultheria. [Oil of Wintergreen.]

(Ō′LḘ-ŬM GÂUL-THḚ′RĮ-Æ.)

"A volatile oil distilled from the leaves of Gaultheria procumbens, Linné (Wintergreen; nat. ord. Ericaceæ), consisting almost entirely of Methyl Salicylate [$CH_3C_7H_5O_3 = 151·64$], and nearly identical with Volatile Oil of Betula." *U. S.*

Oil of Teaberry, Oil of Partridge-berry.

The volatile oil of gaultheria is largely obtained in the United States by distillation of the plant. It probably does not exist in the plant, but is formed by a reaction between water and a neutral principle analogous to amygdalin, to which Prof. Procter has given the name of *gaultherin*. (*A. J. P.*, xv.) This substance, which was called by Schneegans *bétulase*, probably exists in all the numerous plants which yield methyl salicylate on distillation. The oil occurs in various of our native plants, and has been detected in *Polygala paucifolia*, *Spiræa ulmaria*, *Spiræa lobata*, and *Gaultheria hispidula*. T. E. de Vrij found it in considerable proportion in the *Gaultheria leucocarpa* and *G. punctata*, plants which are abundant in the volcanic regions

of Java (*A. J. P.*, 1879); whilst Bourquelot (*Comp.-Rend. Soc. d. Biolog.*, iii. 1896) detected it in *Monotropa hypopythis*, in *Polygala senega*, and in other species of Polygala. (See also *A. J. P.*, 1898, 412.) Much of the commercial oil of wintergreen is obtained from *Betula lenta.*

Oil of gaultheria when freshly redistilled is nearly colorless, but as found in commerce has a brownish-yellow or reddish color.* It is of a sweetish, slightly pungent, peculiar taste, a very agreeable characteristic odor, and a slightly acid reaction. It is the heaviest of the known essential oils, having the "specific gravity 1·175 to 1·185 at 15° C. (59° F.). Boiling point, 218° to 221° C. (424·4° to 429·8° F.). It deviates polarized light slightly to the left. In other respects it has the same properties and conforms to the same reactions and tests as Methyl Salicylate (see *Methyl Salicylas;* also *Oleum Betulæ Volatile*)." *U. S.* It is stated to have been largely adulterated with chloroform. This and other impurities are to be detected by a comparison of the specific gravities and boiling points, or by fractional distillation. It is readily soluble in alcohol. When heated to about 80° C. (176° F.), the Oil should not yield a colorless distillate having the characteristics of chloroform or of alcohol (*A. J. P.*, 1873, p. 521). Another distinguishing property is that in aqueous solution it gives a purple color with ferric salts. Oil of sassafras may be detected by the separation of a deep-red resinous mass on treatment with nitric acid in the cold. Japanese oil of camphor and other light volatile oils used as adulterants can be detected by simply dropping the suspected oil in water: if pure, it sinks in a few seconds; if adulterated, some minutes are required. Prof. Procter proved that oil of gaultheria has acid properties and contains *salicylic acid.* (See *Salix.*) M. Cahours confirmed this, and showed that one-tenth of the oil consists of a peculiar hydrocarbon, which he called *gaultherilene*, and the remaining nine-tenths of *methyl salicylate* or the methyl ester of salicylic acid, $CH_3.C_7H_5O_3$. A product having the properties of the latter compound was obtained by distilling a mixture of methyl alcohol, salicylic acid, and sulphuric acid. (*A. J. P.*, xiv. 211, xv. 241.) Trimble and Schroeter (*Ibid.*, 1889, 398) found that the amount of the hydrocarbon *gaultherilene* was much less than that stated by Cahours,—in fact, only 0·3 per cent. By analysis and vapor-density determination they fixed its formula as $C_{15}H_{24}$, but they state that it may consist of a solid and a liquid portion. Power and Kleber (*Fritzsche Bros. Circ.*, No. 7) assert that this hydrocarbon belongs to the paraffin series, and state that it is probably *triacontane*, $C_{30}H_{62}$. They also find in the oil an aldehyde or ketone, an apparently secondary alcohol, $C_8H_{16}O$, and an ester, $C_{14}H_{24}O_2$. *Artificial oil of wintergreen* is now extensively manufactured and used instead of the natural oil. For a process by H. T. Thayer, see *A. J. P.*, 1895, 244. (See *Methyl Salicylas*, p. 869.) The oil of gaultheria is very largely used on account of its pleasant flavor; it may, however, be employed as a substitute for salicylic acid with excellent results. One hundred and sixty-nine grains of the oil contain one hundred and fifty-two grains of methyl salicylate, and are therefore equivalent to one hundred and thirty-eight grains of salicylic acid. An elaborate research by Dr. H. C. Wood (*Therap. Gaz.*, vol. ii. p. 76) proved that this drug acts physiologically like salicylic acid. When taken in moderate amounts it is, like that acid, broken up in the system and eliminated as salicyluric acid, etc. It is capable of causing fatal poisoning. Half an ounce produced in a boy severe vomiting, purging, epigastric pain, hot skin, frequent pulse, slow and labored respiration, dulness of hearing, and, notwithstanding excessive gastric irritability, an uncontrollable desire for food; he finally re-

* *Distillation of Oil of Gaultheria.* Mr. Isaac Edward Leonard states that oil of wintergreen, first made in Luzerne County, Pa., in 1863, has since been distilled there in great quantities. The entire plant is employed, and it gives the greatest yield during the months of July and August.

The still is generally a wooden box, about eight feet long, four feet wide, four feet high, with a copper bottom and stayed with bolts. The head of the still is copper, and connecting with this is a circular worm of the same material or of tin, placed in a barrel. The still being filled with wintergreen to within about twelve inches of the top, a sufficient quantity of water is added, and this is allowed to macerate from ten to twelve hours. The fire being started, the distillation commences, and continues for about eight hours; but during the first two or three hours ninety per cent. of the oil has passed over. For collecting the distillate, most of the distillers use a wide-mouthed bottle, fitted with a large cork having two holes. A small funnel is put into one of the holes, so that the beak is below the shoulder of the receiving vessel, and connected with the other hole is a suitable pipe forming an outlet. The oil and the water separate, the oil going to the bottom, and the water passes into a larger receptacle, where it is reserved for a subsequent operation (cohobation).

Occasionally the oil is very highly colored, and the wholesale dealers have three ways of "cleaning" it,—redistillation, filtration, and decolorization. The oil to be decolorized is put into a bottle, crystals of citric acid are added, and the whole is allowed to stand, agitating occasionally, until the oil is colorless, or nearly so. On experimenting with nine quarts of wintergreen fruit, the author found it contained one and one-half drachms of oil. In experimental distillation he found that the lower specific gravity is due to the separating of the oil from the water too quickly, and that the higher specific gravity is obtained by letting the distillate stand from twenty-four to forty-eight hours before separating the oil from the water. (*A. J. P.*, 1884, p. 264.)

covered. (*Medical Examiner*, N. S., viii. 347.) A woman survived after having taken half an ounce (*N. Y. Med. Journ.*, 1875); but the same amount has caused death (*Ibid.*, 1867).

OLEUM GOSSYPII SEMINIS. U. S. Cotton-Seed Oil.

(Ō'LḘ-ŬM GOS-SŸP'Ḭ-Ī SĔM'Ḭ-NĪS.)

"A fixed oil expressed from the seed of Gossypium herbaceum, Linné, and of other species of Gossypium (nat. ord. Malvaceæ), and subsequently purified." *U. S.*

This fixed oil has no other medical properties than those of a bland neutral oil, and has been introduced especially on account of its use in official liniments. The amount of cotton-seed crushed annually now approaches 1,500,000 tons, and the production of crude cotton-seed oil amounts to over 59,000,000 gallons, valued at more than $14,000,000. Of this production, about one-fourth goes into the manufacture of "compound lard" and "cottolene," a still larger amount is exported as cotton-seed oil, and the remainder is used in admixture with drying oils and for soap-stock. The oil cake is largely exported to England, where it is used as food for cattle, and the oil to France, Italy, and other olive-growing countries of Europe, whence much of it returns to us mixed with olive oil. The exportation of cotton-seed oil for 1895 amounted to 21,187,728 gallons, valued at $6,813,313; for 1896 to 19,445,848 gallons, valued at $5,476,510; and for 1897 to 27,198,882 gallons, valued at $6,897,361. For a description of the process of extraction, see *A. J. P.*, 1896, 42; also 1898, 497.

This oil is obtained by expression from the seeds previously deprived of their shells. In this state they yield two gallons of oil to the bushel. As first obtained, it is thick and turbid, but it deposits a portion of its impurities on standing. Besides this crude oil, there are three varieties in commerce, more or less purified, recognized as the *clarified*, the *refined*, and the *winter-bleached*. The last mentioned is of a pale straw-color, a mild peculiar odor, and a bland sweetish taste, not unlike that of almond oil. The oil is used in the preparation of woollen cloth and morocco leather, and for oiling machinery. It has been found to be an excellent substitute for almond and olive oil in most pharmaceutical preparations in which they are employed; but it does not answer well in the formation of lead plaster. Citrine ointment carefully prepared with it, too great heat being avoided, retains long a rich orange color and proper unctuous consistence. It is officially described as "a pale yellow, oily liquid, without odor, and having a bland, nut-like taste. Specific gravity, 0·920 to 0·930 at 15° C. (59° F.). Very sparingly soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide. On cooling the oil to a temperature below 12° C. (53·6° F.), particles of solid fat will separate. At about 0° to —5° C. (32° to 23° F.), the Oil solidifies. When the Oil is brought in contact with concentrated sulphuric acid, a dark reddish-brown color is instantly produced. If 6 Gm. of the Oil be thoroughly shaken, in a test-tube, for about two minutes, with a mixture of 1·5 Gm. of nitric acid and 0·5 Gm. of water, then heated in a bath of boiling water for not more than fifteen minutes, the Oil will assume an orange or reddish-brown color, and, after standing for twelve hours at the ordinary temperature, will form a semi-solid mass. If 5 C.c. of the Oil be thoroughly shaken, in a test-tube, with 5 C.c. of an alcoholic solution of silver nitrate (made by dissolving 0·1 Gm. of silver nitrate in 10 C.c. of deodorized alcohol and adding 2 drops of nitric acid), and the mixture heated for about five minutes in a water-bath, the Oil will assume a red or reddish-brown color." *U. S.*

Cotton-seed oil has been examined by Dr. A. Adriani (*Chem. News*, Jan. 7, 1865, p. 5). The product of the expressed seeds is from 15 to 18 per cent. In its impure state it is dark reddish-brown, not quite clear, and contaminated with mucilage and albumen. When boiled with an alkaline solution, crude cotton-seed oil is saponified, and the resultant soap rapidly oxidizes on exposure to air, with production of a fine purple or violet-blue coloration.* This reaction is characteristic of crude cotton-seed oil. The sp. gr. of the crude oil varies from 0·928 to 0·930; that of the refined oil, from 0·922 to 0·926.

The oil is clarified by first boiling it with water, to separate the mucilage, and then heating it with a weak solution of caustic soda, which combines with the coloring matter and saponifies a part of the oil. The mixture becomes filled with black flocks, which deposit on standing and leave the oil but slightly colored. The loss in refining is usually from 4 to 7½ per cent., but

* "Cotton-seed blue" is stated by Kuhlmann to have the composition $C_{17}H_{24}O_4$. It is amorphous, readily destroyed by oxidizing agents, insoluble in water, diluted acids, and alkalies, soluble in alcohol and ether. The unoxidized coloring matter of cotton-seed oil has also been investigated by J. Longmore, who finds it to be a pungent, golden-yellow product, which dyes well and perfectly fast on wool and silk. (Allen, *Commercial Organic Analysis*, 2d ed., 1887, p. 113.)

occasionally amounts to 12 or 15. As this oil is much used for adulterating olive oil, a test to distinguish it is very desirable: according to Mr. R. Reynolds, mercuric nitrate will answer the purpose. Of this a test-solution may be made by dissolving, without heat, 6 parts of mercury in 7·5 parts of nitric acid of 1·36. This salt has the effect, when mixed with olive oil, of entirely solidifying and hardening it upon standing; while under the same circumstances the cotton-seed oil remains fluid. If the two oils are mixed, an intermediate effect is produced, the oil, though possibly solidified, remaining soft and pasty, and not becoming hard like pure olive oil. (*P. J. Tr.*, 2d ser., vii. 226.) For Bechi's test see *Oleum Olivæ*. S. S. Bradford (*A. J. P.*, 1882, p. 481) states that a reddish color is developed when cotton-seed oil is mixed with solution of lead subacetate.

OLEUM HEDEOMÆ. U. S. Oil of Hedeoma. [Oil of Pennyroyal.]

(Ō'LĘ-ŬM HĔD-Ę-Ō'MÆ.)

"A volatile oil distilled from Hedeoma. It should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.*

This oil, though analogous in properties to the oil of European pennyroyal, is derived from a distinct plant (*Hedeoma pulegioides*), peculiar to North America. It has a light-yellow color, with the odor and taste of the herb, and a neutral reaction. Its "specific gravity is 0·930 to 0·940 at 15° C. (59° F.). The Oil should form a perfectly clear solution with twice its volume of a mixture of 3 volumes of alcohol and 1 volume of water, this solution being neutral or slightly acid to litmus paper. It is also readily soluble in carbon disulphide, or in glacial acetic acid." *U. S.* Its chemical composition has been investigated by E. Kremers (*A. J. P.*, 1887, p. 535) and F. W. Franz (*Ibid.*, 1888, p. 161). Each of them found a body of the composition $C_{10}H_{18}O$, boiling at 217°–218° C. (constituting, according to Franz, about 33 per cent. of the oil). For this the name *hedeomol* is proposed. Franz found also a body of the composition $C_{10}H_{17}O$, boiling at 220°–225° C., and constituting 12 per cent. of the oil; likewise a body of the composition $C_6H_{12}O$, boiling at 165°–170° C., and constituting about 0·7 per cent. of the oil. Both investigators found *formic* and *acetic acids*, and Kremers considers *isaheptoic acid* also to be present. Beckmann and Pleissner (*Ann. der Ch. und Pharm.*, 262, p. 1) found in American as well as in Spanish and Algerian pennyroyal oil a ketone, $C_{10}H_{16}O$, to which they gave the name of *pulegone*. This compound forms with hydroxylamine an oxime, $C_{10}H_{16}NOH,H_2O$, crystallizing in beautiful needles melting at 157° C., and with hydrogen bromide a crystalline compound melting at 40·5° C. The two compounds of the formula $C_{10}H_{18}O$, discovered by Kremers (*Pharm. Rundschau*, ix. p. 130), are also ketones and yield corresponding oximes. The oil may be used as a remedy in flatulent *colic* and *sick stomach*, to correct the operation of nauseating or griping medicines. It is also much employed as a domestic remedy in *amenorrhœa*. The dose is from two to ten drops (0·12–0·6 C.c.).

OLEUM JUNIPERI. U. S., Br. Oil of Juniper.

(Ō'LĘ-ŬM JŪ-NĬP'Ę-RĪ.)

"A volatile oil distilled from the fruit of Juniperus communis, Linné (nat. ord. Coniferæ)." *U. S.* "The oil distilled from the full-grown unripe green fruit of Juniperus communis, Linn." *Br.*

Oleum Fructus (vel Baccæ) Juniperi; Essence de Genièvre, *Fr.*; Wachholderbeeröl, *G.*

The proportion of oil which juniper berries afford is stated very differently by different authors. Trommsdorff obtained 1 per cent. The highest quantity given in the table of Recluz is 2·34, the lowest 0·31 per cent. Zeller gives as the product of the fresh ripe fruit 1·3 per cent., of that a year old 0·86 per cent. (*Centralbl.*, März, 1855, p. 207.) The berries are most productive when bruised. The oil of juniper consumed in this country is brought from Europe, and is believed to be procured chiefly from the tops of the plant, being sold for a price which is altogether incompatible with the idea that it is prepared from the fruit alone. It is colorless, or of a light greenish yellow, with terebinthinate odor and hot acrid taste. Oil of juniper has a neutral reaction; sp. gr. from "0·850 to 0·890 at 15° C. (59° F.). Soluble in about 4 times its volume of alcohol, forming a somewhat turbid liquid, which is neutral or slightly acid to litmus paper. Also soluble in an equal volume of carbon disulphide." *U. S.* "Specific gravity 0·865 to 0·890. The Oil is soluble, with slight turbidity, in 4 times its own volume of a mixture of equal parts of *absolute alcohol* and *alcohol* (90 per cent.)." *Br.* According to Flückiger (*Pharm. Chem.*, 2d ed., 1888, 402), it is composed essentially of two hydrocarbons, the more abundant of which, boiling at 160° C., has been shown by Wallach

to be *pinene*, $C_{10}H_{16}$. Above 175° C. another oil is obtained, which seems to be *cadinene*, $C_{15}H_{24}$. It also contains a small amount of an ester to which the peculiar juniper-like odor and taste are due. This has been called *juniper camphor*. Oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture being less than that of the unadulterated oil of juniper.

The oil is stimulant, carminative, and diuretic, and is very useful in combination with other remedies in debilitated *dropsical* cases. To it Holland gin owes its peculiar flavor and diuretic power. Sir James Simpson, of Edinburgh, considered it an efficient diuretic when administered through the lungs. A teaspoonful of the oil is put into a vessel of hot water, and the patient directed to inhale the vapors. (*Bost. Med. and Surg. Journ.*, March 12, 1868, p. 96.) The dose is from five to fifteen drops (0·3–0·9 C.c.), and may be considerably increased.*

OLEUM LAVANDULÆ. Br. Oil of Lavender.

(Ō′LḘ-ŬM LA-VĂN′DŮ-LÆ.)

"The oil distilled from the flowers of Lavandula vera." *Br.*

Essence de Lavande, *Fr.*; Lavandelöl, *G.*

This oil is usually distilled from the flowers and flower-stems conjointly, though of finer quality when obtained from the former exclusively. (See the next article, *Oleum Lavandulæ Florum.*) Dried lavender flowers are said to yield from 1 to 1·5 per cent. of oil. According to Zeller, the fresh flowers yield 1·03, the dried 4·3, the whole fresh herb in flower 0·76 per cent. It is stated that the lavender produced by an acre of ground under cultivation will yield from 10 to 12 pounds of the oil. (*P. J. Tr.*, 1864, p. 257.) The oil is very fluid, of a lemon-yellow color, with the fragrance of the flowers, and an aromatic, burning taste. That met with in commerce has the sp. gr. 0·898 at 68° F., which is reduced to 0·877 by rectification (*Berzelius*), or 0·886 (*Buignet*). It is lævogyrate. According to Brande, the sp. gr. of the oil obtained from the whole herb is 0·9206. Alcohol of 0·830 dissolves oil of lavender in all proportions; that of 0·877 only 42 per cent. (*Berzelius.*) Proust states that when allowed to stand in imperfectly-stopped bottles it lets fall a crystalline deposit, which often amounts to one-fourth of its weight. This has been found by M. Dumas to have the same point of volatilization and the same composition as true camphor, but to differ in the total want of rotatory power. It is said that the portion of oil first distilled is most fragrant, and is often kept separate, and sold at a higher price. "Pale yellow or nearly colorless, with the fragrant odor of the flowers, and a pungent bitter taste. Specific gravity not below 0·885. It should dissolve in 3 times its volume of *alcohol* (70 per cent.)." *Br.* The principal constituent is an alcohol, $C_{10}H_{18}O$, identical with the *linalool* discovered by Semmler in linaloe oil. This alcohol boils at from 197°–199° C., and has a sp. gr. of 0·869 at 20° C. Besides linalool, lavender oil contains linalool acetate (from 30 to 45 per cent. in the oil from French flowers, and from 7 to 10 per cent. in the oil from English flowers), *geraniol*, a very small amount of *cineol*, and traces of a sesquiterpene. The oil of spike contains about 30 per cent. of cineol and but small quantities of esters. Flückiger states (*A. J. P.*, 1885, p. 132) that from *Lavandula vera* 80,000 to 100,000 kilogrammes of oil are produced at Grasse every year, and from *Lavandula spica* 20,000 to 25,000 kilogrammes. It is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of *nervous languor* and *headache.* The dose is from one to five drops (0·06–0·3 C.c.).

Oil of Spike is procured from the broad-leaved variety of lavender which grows wild in Europe, the *Lavandula spica* of De Candolle. Its odor is less fragrant than that of common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is used by artists in the preparation of varnishes.

OLEUM LAVANDULÆ FLORUM. U. S. Oil of Lavender Flowers.

(Ō′LḘ-ŬM LA-VĂN′DŮ-LÆ FLŌ′RŬM.)

"A volatile oil distilled from the fresh flowers of Lavandula officinalis, Chaix (nat. ord. Labiatæ). It should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.*

* *Antiseptic Catgut.* Dr. Kocher, of Berne, states that a very fine antiseptic catgut may be made by first soaking the catgut for 24 hours in pure oil of juniper, and then immediately transferring it to alcohol of 95 per cent., in which it is preserved under tension, being wound (tightly stretched) upon a flat reel about 10 inches long. If the gut be placed for a day in glycerin before it is laid in the alcohol, it will become more pliable. The gut must be cut at the point of turning the edges of the reel, and for this reason the latter is chosen of such a size that the cut pieces of catgut shall be of the proper length. (*New Remedies*, September, 1881, p. 270.)

This superior kind of oil of lavender has been introduced into the Pharmacopœia because it was desirable that an inferior sort should not be used in the preparations into whose composition it enters. The properties of the oil are noticed in the preceding article. It is officially described as "a colorless or yellowish liquid, having the fragrant odor of lavender flowers, and a pungent and bitterish taste. Specific gravity, 0·885 to 0·897 at 15° C. (59° F.). It is soluble in all proportions in alcohol (distinction from *oil of turpentine*), and in 3 times its volume of a mixture of 3 volumes of alcohol and 1 volume of water (distinction from, and absence of, *oil of turpentine*); it is also soluble in glacial acetic acid. With an equal volume of carbon disulphide it forms a turbid mixture. The alcoholic solution of the Oil is neutral or slightly acid to litmus paper. When heated on a water-bath, in a flask provided with a well-cooled condenser, the Oil should yield no distillate having the characters of *alcohol*." *U. S.*

OLEUM LIMONIS. U. S., Br. Oil of Lemon.

(Ō'LḘ-ŬM LI-MŌ'NĬS.)

"A volatile oil obtained by expression from fresh Lemon Peel. It should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.* "The oil obtained from fresh lemon peel." *Br.*

Oleum Citri, *P. G.;* Huile de Cédrat, Essence de Citron, Huile de Citron, *Fr.;* Citronenöl, *G.;* Olio de Limone, *It.;* Aceite de Limon, *Sp.*

The exterior rind of the lemon abounds in a volatile oil, which, being contained in distinct cells, may be separated by simple expression. The rind is first grated from the fruit, and then submitted to pressure in a bag of fine cloth. The oil thus obtained is allowed to stand till it becomes clear, when it is decanted, and kept in stoppered bottles. By a similar process, the oil called by the French *huile de cédrat* is procured from the citron. (See *Oleum Bergamottæ* and *Limonis Succus.*) These oils may also be obtained by distillation; but thus procured, though clearer, and, in consequence of the absence of mucilage, less liable to change on keeping, they have less of the peculiar flavor of the fruit; and the mode by expression is generally preferred. A third method of separating the oil, used in Calabria and Sicily, is to put the grated rind into hot water and skim off the oil as it rises to the surface. (*A. J. P.*, 1868, p. 27.) The method employed to obtain the finest oil is, however, that known as the écuelle process. The écuelle is an instrument usually made of tinned copper, bowl-shaped, and armed with concentric rows of short spikes. Attached to the bottom of the bowl is a hollow handle, closed at the bottom. This acts as a reservoir for the oil as the fruit is rubbed by the workmen over the sharp teeth. The oils are brought originally from Italy, Portugal, or the south of France.

The oils of lemons and oranges, as well as those of the other Aurantiaceæ, will keep indefinitely upon admixture with a small proportion of alcohol, say one ounce to a pound of the oil. When wanted for use, a quantity of water equal to that of alcohol, added to the mixture, will unite with the alcohol, and subside, leaving the oil free of the alcohol for all practical purposes. (Carl Früh, *A. J. P.*, 1871, 201.) The great extent of the production and export of Sicilian and Calabrian essential oils (lemon, orange, bergamot, etc.) may be seen from the Italian official statistics, according to which the number of trees producing in 1896 was 17,084,569, yielding 3,337,000,000 fruits. Of these 1,897,000,000 were exported, leaving 1,439,555,000 fruits for home consumption, inclusive of those used in the manufacture of essences. (*Schimmel & Co.'s Report*, Oct. 1897, 23.)

Properties. Oil of lemon is a very volatile liquid, having the odor of the fruit, a warm, pungent, aromatic taste, and a neutral reaction. As commonly procured, it is yellow, but by distillation it is rendered colorless, and, if three-fifths only are distilled, its sp. gr. is reduced to 0·847 at 71° F. "Specific gravity, 0·857 to 0·860 at 15° C. (59° F.). Its optical rotation should not be less than 60° to the right in a 100 Mm. tube, and at a temperature of about 15° to 20° C. (59° to 68° F.). Soluble in three times its volume of alcohol, the solution being neutral or slightly acid to litmus paper; also soluble, in all proportions, in absolute alcohol, carbon disulphide, or glacial acetic acid. When kept for some time, the Oil should not develop a terebinthinate odor or taste (absence of *oil of turpentine* or of *other oils consisting chiefly of pinene*)." *U. S.* "Specific gravity 0·857 to 0·860. It should rotate the plane of a ray of polarized light not less than 59° to the right in a tube 100 millimetres long; and if 100 volumes be fractionally distilled, the 10 volumes first collected should not produce a rotation differing by more than 2° from that produced by the original Oil." *Br.* Oil of lemon contains a small amount of *pinene*, with dextrogyrate *limonene*, about 7 to 8 per cent. of *citral*, $C_{10}H_{16}O$, an aldehyde yielding geraniol upon reduction, and a small amount of *citronellal*, $C_{10}H_{18}O$, also an

aldehyde. Of these the citral is the constituent to which the oil chiefly owes its aroma and value. Umney and Swinton (*P. J. Tr.*, 1898, 196) state that citral, citronellal, and an ester of geraniol are all necessary to form the true odor of oil of lemon. Citral boils under normal atmospheric pressure at from 228°–229° C. without decomposition if pure, and, like aldehydes, forms stable compounds with alkaline bisulphites. Schimmel & Co. now prepare the citral in a pure state, and recommend its use for enriching the ordinary oil of lemon. As yet no thoroughly reliable method for determining the percentage of citral in a mixture has been devised. Garnett's method (*Chem. and Drug.*, 48, 599) of reducing the citral to geraniol and then acetylizing this and titrating with alcoholic potash does not, according to Schimmel & Co., yield reliable results.

It is often adulterated by the fixed oils and by alcohol; but in this country the most frequent sophistication is with oil of turpentine, which is difficult of detection from its similar composition and specific gravity. Perhaps the best test of the presence of this oil is the terebinthinate smell produced when the adulterated oil is evaporated from heated paper. Oil of lemon procured by expression is apt to let fall a deposit and to undergo chemical change. Mr. J. S. Cobb has found no method so effectual to obviate this result, and at the same time to retain unimpaired the flavor of the oil, as to shake it with a little boiling water and allow the mixture to stand. A mucilaginous matter separates, and floats on the surface of the water, from which the purified oil may be decanted. (*Ann. of Pharm.*, ii. 86.)

Medical Properties and Uses. Oil of lemon has the stimulant properties of the aromatics, but is used chiefly to impart flavor to other medicines.

OLEUM LINI. U. S., Br. Linseed Oil. [Oil of Flaxseed.]

(Ō′LḘ-ŬM LĪ′NĪ.)

"A fixed oil expressed from Linseed without the use of heat." *U. S.* "The oil expressed from Linseed at ordinary temperatures." *Br.*

Huile de Lin, *Fr.;* Leinöl, Leinsamenöl, *G.;* Olio di Lino, *It.;* Aceite de Linaza, *Sp.*

This oil is obtained by expression from the seeds of *Linum usitatissimum*, or common flax, which, according to M. Berjot, contain 34 per cent. (*Journ. de Pharm.*, Avril, 1863, p. 277.) In its preparation on a large scale, the seeds are usually roasted before being pressed, in order to destroy the gummy matter contained in their coating. The oil is thus obtained more free from mucilage, but more highly colored and acrid, than when procured by cold expression. For medical use, therefore, it should be prepared without heat; and, as it is apt to become rancid quickly on exposure, it should be used as soon after expression as possible. It may, however, be rendered sweet again by agitation with warm water, rest, and decantation. It is said to be obtained purer and in larger proportion by treating the crushed seeds with carbon disulphide, than by expression. (See *A. J. P.*, xxvi. 265.) Flaxseed oil is "a yellowish or yellow,* oily liquid, having a slight, peculiar odor, and a bland taste. When exposed to the air it gradually thickens, and acquires a strong odor and taste; and if spread, in a thin layer, on a glass plate, and allowed to stand in a warm place, it is gradually converted into a hard, transparent, resin-like mass (absence of *non-drying oils*). Specific gravity, 0·930 to 0·940 at 15° C. (59° F.). It does not congeal above —20° C. (—4° F.). Soluble in about 10 parts of absolute alcohol, and, in all proportions, in ether, chloroform, benzin, carbon disulphide, or oil of turpentine. It should not more than slightly redden blue litmus paper previously moistened with alcohol (limit of *free acid*). If 2 C.c. of the Oil be shaken with 1 C.c. of fuming nitric acid and 1 C.c. of water, it should neither completely nor partially solidify, even after standing for one or two days (absence of *non-drying oils*). If 10 C.c. of the Oil, contained in a small flask, be mixed with a solution of 3 Gm. of potassium hydrate in 5 C.c. of water, then 5 C.c. of alcohol added, and the mixture heated for about five minutes on a water-bath, with occasional agitation, a dark-colored but clear and complete solution should be obtained. If this liquid be diluted with water to the measure of 50 C.c., then cooled, and shaken with 50 C.c. of ether, the clear, ethereal layer, after having separated, should not show a bluish fluorescence, and, when carefully decanted, and allowed to evaporate spontaneously, should

* The following method of bleaching flaxseed, rapeseed, and poppy-seed oils is recommended by C. Puscher. He mixes 100 kilogrammes of the oil with 2 kilogrammes of a mixture of equal weights of sulphuric acid and alcohol of 96 per cent. The sulphuric acid mixes uniformly with the oil; the mixture soon assumes a green turbidness, which afterwards becomes black; and in 24 or 48 hours the liquid becomes clear by the deposition of a black sediment. It is necessary to wash the oil with hot water, to separate the little remaining acid. Linseed oil in bulk shows merely a yellowish tint; the other oils mentioned become quite colorless. (*A. J. P.*, 1873, p. 110.)

leave not more than a slight, and not oily, residue (absence of *paraffin oils*)." *U. S.* "Viscid, yellow, with a faint but distinct odor, and bland taste. Specific gravity 0·930 to 0·940. It is soluble in 10 parts of *alcohol* (90 per cent.), and in Oil of Turpentine. It gradually thickens by exposure to the air, forming, when spread in a thin layer on glass, a hard transparent varnish. It does not congeal above —4° F. (—20° C.)." *Br.* It has the property of drying or becoming solid on exposure to the air, acquiring during the process a strong odor and taste, and increasing as much as 12 per cent. of its weight, owing to the formation of *linoxyn* by atmospheric oxidation. The drying property resides in a constituent which, to distinguish it from the olein of the non-drying oils, is named *linolein*, and is the glyceride of *linoleic acid*, $C_{18}H_{28}O_2$. The formula of linoleic acid is not positively accepted as that just given. Hazura (*Journ. Soc. Chem. Ind.*, 1888, 506) states that the liquid fatty acids consist of about 5 per cent. of *oleic acid*, $C_{18}H_{34}O_2$, 15 per cent. of *linoleic acid*, $C_{18}H_{32}O_2$, 65 per cent. of *isolinoleic acid*, $C_{18}H_{32}O_2$, and 15 per cent. of *linolenic acid*, $C_{18}H_{30}O_2$. Boiled with litharge, red lead, manganese dioxide, and other so-called "driers," it absorbs oxygen still more rapidly, and gains 14 per cent. in weight. Its acrimony is owing to the presence of a small proportion of an acrid oleoresin. From its drying property, it is useful in painting and in making printers' ink.

It is said that crude cod-liver oil has been used for the adulteration of the oil of flaxseed, especially where the latter is intended for preparing printers' ink. Mr. Aug. Morell detects the adulteration by the following method. Take 10 parts by weight of the suspected oil, mix it in a small cylindrical glass tube with 3 parts of crude nitric acid, agitate the mixture well, and allow it to rest. If cod-liver oil be present, the oily layer at top will assume a dark-brown to blackish-brown color, while the acid at bottom will vary from bright orange to orange or dark yellow. So little as 3 per cent. of cod-liver oil may thus be detected. If the flaxseed oil be pure, it will become, during the agitation, first sea-green, and afterwards dirty greenish yellow, the acid being bright yellow.

Medical Properties and Uses. The oil is laxative in the dose of a fluidounce (30 C.c.), but, on account of its disagreeable taste, is seldom given internally. It has, however, been highly recommended as a cure for *piles*, in the dose of two ounces (60 C.c.) of the fresh oil morning and evening. It is sometimes added to purgative enemata.*

OLEUM MENTHÆ PIPERITÆ. U. S., Br. Oil of Peppermint.

(Ō'LE-ŬM MĔN'THÆ PĪ-PE-RĪ'TÆ.)

"A volatile oil distilled from Peppermint." *U. S.* "The oil distilled from fresh flowering peppermint, Mentha piperita, Sm." *Br.*

Essence de Menthe poivrée, *Fr.*; Pfefferminzöl, *G.*

Peppermint varies exceedingly in the quantity of oil which it affords. Four pounds of the fresh herb yield, according to Baumé, from a drachm and a half to three drachms of the oil. Zeller gives as the product of the fresh herb from 0·37 to 0·68 per cent., of the dried 1·14 per cent. The yield is generally less than 1 per cent. This oil is largely distilled in the States of Michigan, Indiana, and New York. For a valuable account of its method of production in Michigan, by A. M. Todd, see *A. J. P.*, 1888, 328. The oil is also largely produced in Japan. (See illustrated paper, *Chem. and Drug.*, 1896, 601.) It is of a greenish-yellow color or nearly colorless, but becomes reddish by age. Its odor is strong and aromatic, its taste warm, camphorous, and very pungent, but succeeded, when air is admitted into the mouth, by a sense of coolness. Its sp. gr. is stated differently at from 0·902 to 0·920 (0·900–0·920 at 15° C. (59° F.), *U. S.*†); its boiling point is 365° F.; its reaction is neutral. "The Oil does not fulminate with iodine. It forms a clear solution with an equal volume of alcohol, becoming turbid when somewhat further diluted, and is soluble, in all proportions, in carbon disulphide, and in glacial acetic acid. The alcoholic solution of the Oil is neutral to litmus paper. If 5 drops of the Oil be added to 1

* *Oiled Paper.* A substitute for waxed cloth for the dressings of wounds and ulcers, prepared in the following manner by M. Gauthier, of Geneva, with flaxseed oil, has been highly recommended. To facilitate its drying, 3 liters (about 6·4 pints) of the oil are boiled for an hour or two with 30 grains of lead acetate, 30 grains of litharge, 15 grains of yellow wax, and 15 grains of turpentine. Thus prepared, the oil is spread upon silk-paper by means of a brush on both surfaces. On the top of the first sheet another is then placed so as to overlap it at one corner. The lower surface of the second sheet thus becomes impregnated with the oil, which now requires to be applied only to the upper. Any desired number of sheets may be thus successively superimposed. They are then separated, and suspended in a drying apartment, attached to a cord by means of hooks or pins. When dry, they should be sprinkled over with chalk, to prevent adhesion, and packed away. (*Journ. de Pharm.*, Mai, 1860, p. 363.)

† The specific gravity of pure American oil of peppermint should not be below 0·907 nor above 0·917. (*A. J. P.*, 1887, 285.)

C.c. of glacial acetic acid, and the mixture gently warmed, the liquid will assume a blue color, with a red fluorescence. If 2 C.c. of the Oil be mixed with 1 C.c. of glacial acetic acid, and 1 drop of nitric acid added, the liquid will soon acquire a green, greenish-blue, blue, or violet tint with a copper-red fluorescence. If 1 C.c. of the Oil be dissolved in 5 C.c. of alcohol, 0·5 Gm. of sugar and 1 C.c. of hydrochloric acid added, and the mixture gently heated, a deep-blue or violet color will gradually be produced. If to 5 C.c. of nitric acid 1 drop of the Oil be added, and the mixture gently agitated, and allowed to stand for about three hours, it should have a yellowish, but not a bright red color (absence of *oil of camphor* and of *oil of sassafras*). If a portion of the Oil, contained in a test-tube, be placed in a freezing mixture of snow (or pounded ice) and salt for fifteen minutes, it should become cloudy and thick, and after the addition of a few crystals of menthol, being still exposed to cold, it should soon form a crystalline mass (distinction from *dementholized oil*). When heated on a water-bath, in a flask provided with a well-cooled condenser, the Oil should not yield a distillate having the characters of *alcohol*." *U. S.* "Specific gravity 0·900 to 0·920. It should dissolve in four times its volume of *alcohol* (70 per cent.). If a portion of the Oil be cooled to 17° F. (—8·3° C.) and a few crystals of Menthol be added, a considerable separation of menthol should take place." *Br.* It is considerably lævogyrate. (Buignet.) Upon long standing it deposits a stearopten. Berzelius states also that at 8° F. below zero the oil deposits small capillary crystals. These, which are called *peppermint camphor* or *menthol*, $C_{10}H_{19}OH$, melt at 42° C. (107·6° F.), boil at 212° C. (413·6° F.), volatilize unchanged, and, when distilled with phosphoric anhydride, yield a peculiar aromatic product, denominated *menthene*, $C_{10}H_{18}$. A complete summary of the composition of American peppermint oil, given in *Schimmel & Co.'s Report* for April, 1897, shows the following constituents: acetaldehyde, isovaleraldehyde, dimethyl sulphide, amyl-alcohol, isovaleric acid, pinene, phellandrene, cineol, limonene, *menthone*, $C_{10}H_{18}O$, menthol, the acetate and isovalerate of this latter, *lactone*, $C_{10}H_{16}O_2$, and cadinene. Menthol, its oxidation product menthone, and the acetic and isovaleric esters of menthol have been identified as present in English and French peppermint oils, which probably also contain most of the other constituents mentioned above. The polariscope has been shown to be an uncertain guide in determining the quality of oil of peppermint. (A. B. Stevens, *Proc. A. P. A.*, 1888, p. 97.) Professor Flückiger has discovered that from 50 to 70 drops of peppermint oil, shaken with one drop of nitric acid, sp. gr. 1·2, turn faintly yellowish brown, and after an hour or two a most beautiful blue violet or greenish blue, by transmitted light, or copper color by reflected light. Either a greater amount of acid or heating hastens the reaction. The color is very persistent. The presence of 5 per cent. of turpentine does not interfere with the reaction. (*P. J. Tr.*, Feb. 1871.) This oil is frequently adulterated with alcohol, and occasionally, there is reason to believe, with oil of turpentine, and even oil of copaiba. Oil of turpentine is detected by its odor, by its deficient solubility in cold alcohol, and by its imparting the property of exploding with iodine. According to H. Martin, the copaiba is to be detected by the mass acquiring the consistence of butter when heated to boiling with concentrated sulphuric acid. (*Neues Repert. für Pharm.*, xvii. 635.) It is stated by the Messrs. Hotchkiss that in much of the land under culture with peppermint in this country other oil-producing plants are carelessly allowed to grow, which, being gathered and distilled with the peppermint, contaminate the product. (*A. J. P.*, xxvii. 222.) The plant which has proved most troublesome to the mint-growers is of the Erigeron family, and Vigier and Cloez have given the following tests to detect oil of erigeron, which will indicate the presence of eight or ten per cent. of it. Concentrated caustic potash does not saponify erigeron oil, but colors it orange-red in the cold; on heating, the color deepens till part of the oil separates as a reddish-purple viscid mass. This reaction does not show itself with oil freshly distilled at 170° C. Pure mint oils do not give this reaction; in the cold, caustic potash converts them into a white emulsion. On heating, the mixture takes a faint, clear, yellow tinge. But, if a few drops of erigeron oil are introduced, the orange-red color appears quickly on shaking, and develops instantly if the tube is warmed. Mint oil is completely soluble, erigeron oil is completely insoluble, in its own volume of 85-per-cent. alcohol at 15° C. (59° F.). If a suspected sample be agitated with an equal volume of 85-per-cent. alcohol, a milky fluid will be produced if erigeron oil be present, and the insoluble essence will separate in the course of twenty-four hours. The oils of Eucalyptus globulus and turpentine behave in much the same way, and the points which would distinguish the three substances have not yet been determined. But a specimen of mint oil which rotates the polarized ray feebly to the left, makes a turbid mixture with its own volume of 85-per-cent. alcohol, and takes an orange-red tint with caustic potash, may be safely rejected. (*N. R.*,

Jan. 1882; from *L'Union Pharmaceutique.*) Since menthol has been prepared largely from American peppermint oil, much of the latter has been put upon the market deprived of its menthol. To detect this fraud, Messrs. Fritzsche Brothers recommend that a test-tube partially filled with the oil and corked should be placed in a freezing mixture of ice and salt for ten or fifteen minutes. At the end of that time, if the oil have not been tampered with, it will have become cloudy, thick, or of a jelly-like consistence. If then four or five small crystals of menthol be added, and the tube be replaced in the freezing mixture, the oil will in a short time form a solid frozen mass of crystals. For another method of testing dementholized oil, see a paper by E. C. Federer, *Pharm. Era*, 1887, 36; also *Pharm. Era*, 1887, 97. Power and Kleber first proposed (*Pharm. Rund.*, 1894, 157) to estimate the menthol in oil of peppermint by acetylizing a sample and saponifying an exactly weighed portion of the acetylized oil after washing, drying, and filtering the same. Kebler (*A. J. P.*, 1897, 192) proposed to take instead a weighed quantity of the oil, acetylize it, and then saponify the product after washing and neutralizing it. In *Schimmel & Co.'s Report* for October, 1897, Kleber criticises Kebler's modification, and claims greater accuracy for the original method. Of course this determination gives the total menthol; a determination of the combined menthol is had by titrating with alcoholic alkali. Quetting & Co. furnish the following test for detecting the presence of oil of pennyroyal: "Take one drachm chloral hydrate and half a drachm C. P. sulphuric acid; mix them in a glass mortar, add a few drops of alcohol, and stir until it becomes clear. Then use this mixture in equal proportions with the suspected oil in a small porcelain dish, and mix thoroughly together. The result will be a fine cherry color, if the oil be pure; otherwise, if mixed with pennyroyal, it will turn a dark olive-green, more or less according to the extent of adulteration." (*N. R.*, Jan. 1882.) Such impurities may usually be detected by the altered odor of the oil. Prof. Flückiger has found that chloral hydrate develops only a slightly brown or yellow color, whilst anhydrous chloral changed some specimens of the oil to brown and others to green. He also found great differences in the action of sodium bisulphate, the coloring varying from green to rose-red or violet. (*A. J. P.*, 1874, 274.) According to Trebault, when picric acid is added in the cold no change occurs for half an hour, when a green color suddenly develops. The green produced has a showy red fluorescence. Sulphuric acid develops a rose color, passing through reddish yellow to reddish brown; hydrochloric acid a rose color, rather slowly; nitric acid a rose color, then red, soon becoming greenish. (For further particulars, see *P. J. Tr.*, June, 1874, p. 977.) Dr. C. Roucher states that when to acetic acid is added one-twentieth of its weight of oil of peppermint, with agitation, in an hour the liquid becomes deep blue by transmitted and a cinnabar-red by reflected light. The coloration is not stable, but passes through green to yellow in the light. To detect alcohol, Hager puts ten to fifteen drops of the oil in a test-tube with a piece of tannic acid the size of a pea; if even one-half per cent. of alcohol be present, after two or three hours the tannin will be softened or dissolved. (*A. J. P.*, xliv. 104.)

Chinese Oil of Peppermint has not found its way to any extent into commerce, yet it has recently attracted much attention. According to Mr. John Mackey, some of it has reached London in cylindrical tin canisters, and it is to be obtained in San Francisco. Some specimens resemble the ordinary oil, but become solid in cold weather; others remain liquid and show no tendency to deposit a camphor; whilst others are solid crystalline masses at all temperatures. It seems probable that the original Chinese oil contains a great excess of menthol, and constitutes the variety first spoken of, and that the solid and liquid oils are prepared by separating it into its two constituents. The solid oil Flückiger states not to differ from American menthol. (See *P. J. Tr.*, v. 366, 825.)

Oil of peppermint is stimulating and carminative, and is much used in *flatulence*, *nausea*, *spasmodic pains* of the stomach and bowels, and as a corrigent or adjuvant of other medicines. In *neuralgia* it is one of the best external remedies at our command, and is said to have been used in China from time immemorial. A cloth wet with it is to be laid upon the affected part, evaporation being restrained by oiled muslin or other covering. In *rheumatism* also it is a very useful anodyne counter-irritant. The dose is from two to six drops (0·12–0·36 C.c.), and is most conveniently given rubbed with sugar and then dissolved in water. The oil is frequently employed dissolved in alcohol, in the form of *essence of peppermint*, which is an official preparation. (See *Spiritus Menthæ Piperitæ.*)

Menthol resembles carbolic acid in its physiological and therapeutic properties. It is locally stimulant and at the same time anæsthetic, according to Goldscheider having direct paralyzing influence upon the peripheral nerve fibres. In the form of pencil, it has been much used as a

local application in *neuralgia and nervous headaches*. In a ten- to twenty-per-cent. alcoholic or oily solution it is often efficient in *pruritus*, and in the skin irritation which follows the bites of insects. The five- to twenty-per-cent. solution in oil or liquid vaseline has also been used by brush or atomizer with alleged excellent results in *hay fever* or other *catarrhs* of the *nose*, *pharynx*, or *bronchial tubes*, and its inhalation has been especially commended in *asthma* and in *chronic bronchitis* of old people; but it is irritating to the conjunctiva. Although it has been found by Macdonald and Langaard to be a very potent bactericide, it does not seem well adapted to the needs of antiseptic surgery. It has been used in fermentative conditions of the alimentary canal, and has also been strongly commended as a sedative to the gastro-intestinal mucous membranes in *nervous vomiting* and *nervous diarrhœa*. In sufficient dose, it has been shown by Pellacini to be a central nerve paralyzant. Dose, from three to five grains (0·20–0·33 Gm.), from five to ten times a day, best given in capsule.

OLEUM MENTHÆ VIRIDIS. U. S., Br. Oil of Spearmint.

(Ō'LḘ-ŬM MĔN'THÆ VĬR'I-DĬS.)

"A volatile oil distilled from Spearmint." *U. S.* "The oil distilled from fresh flowering spearmint, Mentha viridis, Linn." *Br.*

Essence de Menthe verte, *Fr.;* Römisch-Minzöl, *G.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country, the whole plant being used. It is pale yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany color. Its flavor is analogous to that of oil of peppermint, but less pungent. Its sp. gr. is stated differently at from 0·914 to 0·975 (0·930 to 0·940 at 15° C. (59° F.), *U. S.*); its boiling point is 160° C. (320° F.), its reaction neutral. "With an equal volume of alcohol it forms a clear solution, which is neutral or slightly acid to litmus paper. When somewhat further diluted with alcohol, it becomes turbid. It also yields a clear solution with an equal volume of glacial acetic acid, and with half its volume of carbon disulphide; but with an equal volume of the latter it forms a turbid mixture." *U. S.* "Specific gravity 0·920 to 0·940. The Oil forms a clear solution with its own volume of a mixture of equal parts of *absolute alcohol* and *alcohol* (90 per cent.)." *Br.* Gladstone (*Jahresber.*, 1863, 548) states that it contains a terpene, $C_{10}H_{16}$, and a compound, $C_{10}H_{14}O$, identical with carvone, which boils at 225° C. (437° F.) and has the sp. gr. 0·9515. Henry Trimble (*A. J. P.*, 1885, 484) confirmed these results, working with authentic samples of American oil. Baeyer found lævogyre carvone in both German and American oils to the amount of from 35 to 56 per cent. (*Archiv d. Pharm.*, 212, 283). Schimmel & Co., in an investigation of Russian oil, found from 5 to 10 per cent. of carvone only, but 50 to 60 per cent. of linalool, together with some cineol and lævogyre limonene. (*Report*, April, 1898.) It is used for the same purposes as the oil of peppermint, in the dose of from two to six drops (0·12–0·36 C.c.). An *essence of spearmint*, prepared by dissolving the oil in alcohol, is official. (See *Spiritus Menthæ Viridis.*)

OLEUM MORRHUÆ. U. S., Br. Cod Liver Oil. [Oleum Jecoris Aselli.]

(Ō'LḘ-ŬM MÖR'RHŬ-Æ.)

"A fixed oil obtained from the fresh livers of Gadus Morrhua, Linné, or of other species of Gadus (class, Pisces; order, Teleostei; fam. Gadidæ)." *U. S.* "The oil extracted from the fresh liver of the cod, Gadus Morrhua, Linn, by the application of a temperature not exceeding 180° F. (82·2° C.); and from which solid fat has been separated by filtration at about 23° F. (—5° C.)." *Br.*

Oleum Hepatis Morrhuæ; Cod Oil, *E.;* Huile de Foie de Morue, Huile de Morue, *Fr.;* Leberthran, Stockfisch-leberthran, *G.*

Gen. Ch. Recognized by the ventrals attached under the throat and attenuated to a point.

Gadus morrhua. Linn. *Syst. Nat.*, ed. Gmelin, i. p. 1162; Cuvier, *Règne Animal*, ii. 212; Bloch, *Ichthyologie*, pl. lxiv.—*Morrhua vulgaris.* Storer, *Synopsis of Fishes of N. Am.*, p. 216. The *common cod* is between two and three feet long, with brown or yellowish spots on the back. The body is moderately elongated and somewhat compressed, and covered with soft rather small scales, of which the head is destitute. Of the fins, which are soft, there are three on the back, two anal, and a distinct caudal; and the fin under the throat is narrow and pointed. The jaws are furnished with pointed irregular teeth, in several ranks. The gills are large,

with seven rays. This species of cod inhabits the Northern Atlantic, and is especially abundant on the Banks of Newfoundland, where it finds food adapted to its wants.

Besides the common cod, several other species of Gadus, frequenting the seas of Northern Europe and America, contribute to furnish the cod liver oil of commerce. Among these De Jongh mentions *Gadus callarias*, or *dorsch* (*Morrhua americana* of Storer), *G. molva*, or *ling*, *G. carbonarius*, or *coal-fish*, and *G. pollachius*, or *pollack*, as affording the oil on the coast of Norway, where from 17,000,000 to 35,000,000 of codfish are annually taken;* while on our own coast, in addition to the pollack above mentioned, it is obtained also from the *hake* (*G. merluccius*) and the *haddock* (*G. æglefinus*). It is largely produced on our coast north of Boston.†

Preparation. Fishermen have long been in the habit of collecting this oil, which is largely consumed in the arts, particularly in the preparation of leather. Upon the coasts of Newfoundland, Nova Scotia, and New England, the boats which fish near the shore, being small, soon obtain a load, and, running in to land, deliver their cargoes to persons whose business it is to cleanse and salt the fish. The oil is prepared either in the huts of the fishermen or more largely at establishments to which the livers are conveyed in quantities. These are put into a boiler with water, and heated until they are broken up into a pultaceous mass, which is thrown upon a strainer covering the top of a cask or tub. The liquid portion passes, and upon standing separates into two parts, the oil rising to the surface of the water. The oil is then drawn off, and, having been again strained, is prepared for the market. Another and improved method, which has come into use since the extensive employment of the oil as a medicine, is to heat the livers in a wooden butt by means of low-pressure steam. The pultaceous mass resulting is drained as before mentioned,—the livers themselves containing, besides oil, a considerable portion of watery fluid, which passes off with it in the form of emulsion and separates on standing. In the case of the finest American varieties, the oil, which is made only in the winter months, is drawn off by taps from the bottom of the cooking-butt, and then put into a cooling-house to freeze. The solid frozen mass is put into canvas bags, and submitted, whilst at a low temperature, to severe pressure, whereby the pure liquid oil is forced out, leaving a whitish, tallow-like mass, composed of stearin and liver débris. This residue is sold to the soap-makers, and the oil bottled without further process. The oil thus variously procured is called *shore oil*, and is the purest kind. The manufacture of refined oil by improved processes is developing rapidly in Newfoundland. (See *West. Drug.*, 1897, 13.)

The crews of the larger boats, which fish upon banks far from land, cleanse the fish on board, and, throwing the offal into the sea, put the livers into barrels or other receptacles, where they undergo a gradual decomposition, the oil rising to the surface as it escapes from the disintegrating tissue. The oil which first rises, before putrefaction has very decidedly commenced, approaches in purity to the shore oil, but is somewhat darker and less sweet. This is sometimes drawn off, constituting the *straits oil* of the fishermen. The remaining mass, or the whole, if the portion which first rises be not separated, continues exposed for a variable length of time to the heat of the sun, undergoing putrefaction, until the boat, having completed her cargo, returns to port. The contents of the casks are then put into boilers, heated with water, and treated as already described. Before being finally put into barrels, the oil is heated to expel all its water. Thus prepared, it is denominated *banks oil*, and is of the darkest color, and most offensive to the taste and smell. Much of the oil prepared by the fishermen is collected by the wholesale dealers, who keep it in very large reservoirs of masonry in their cellars, where it becomes clarified by repose, and is pumped into barrels as wanted for sale. By the further exposure, however, which it thus undergoes, it acquires a still more offensive odor; while that which has been originally introduced into barrels, and thus kept secluded from the air, is better preserved. For further details, see *A. J. P.*, xxiii. 97, xxvi. 1.

The oil is sometimes procured by expression. Mr. Donovan recommends the following plan, which affords a very fine oil. The livers, perfectly sound and fresh, are to be placed in a clean iron pot over a slow fire, and stirred until they assume the condition of a pulp, care being taken

* For an account of the mode of fishing for cod and of preparing the oil practised in Norway and Denmark, see *P. J. Tr.*, Jan. 1868, p. 312, also April, 1877, p. 810; and *N. R.*, March, 1878; also *Journ. de Pharm. et de Chim.*, 4e sér., iv. 324, 1866.

† *Dugong Oil.* An oil has been brought into notice, as a substitute for cod liver oil, obtained from two species of *Halicore*, *H. australis* (*Owen*) and *H. dugong* (*Illig*), cetaceous animals inhabiting the rivers and bays of Northern and Eastern Australia and many of the East India islands. The flesh of these animals is said to be delicate and palatable and valued for food. The oil is obtained by boiling the superficial fat. It is bland and sweet, and free from disagreeable taste and smell, so that it may be taken more freely than cod liver oil, which it is thought to equal in virtues. It was introduced into use by Mr. W. Hobbs, a surgeon of Brisbane. (*Chem. News*, Jan. 28, 1860, p. 87, and *A. J. P.*, 1858, p. 335, 1860, p. 230.)

that the mass be not heated beyond 192° F. When this temperature is attained, the pot is to be removed from the fire, and its contents introduced into a canvas bag, through which water and oil will flow into a vessel beneath. After twenty-four hours, the oil is to be decanted and filtered through paper. In this state it is pale yellow, with little odor, and a bland not disagreeable taste.

Properties. Three varieties of cod liver oil are known in the market, the *white* or *pale yellow*, the *brownish yellow*, and the *dark brown*, corresponding to the three commercial varieties already mentioned. These varieties differ in no essential character, but simply from the mode of preparation, the pale being prepared from fresh sweet livers, the dark brown from livers in a state of putrefaction, and the brownish yellow from those in an intermediate state; and the three varieties run together by insensible shades. The color of the pale is from the slightest tint of transparent yellow to a fine golden yellow, that of the light brown very similar to the color of Malaga wine, and that of the dark brown what its name implies, with opacity in mass, but transparency in thin layers. They are of the usual consistence of lamp oil, and have a characteristic odor and taste, by which they may be distinguished from other oils. This smell and taste are familiar to most persons, being very similar to those of shoe-leather,—at least as prepared in this country, where the curriers make great use of cod liver oil. We regard these sensible properties as the most certain tests of the genuineness of the oil. They are much less distinguishable in the pale than in the dark-brown varieties, but we have met with no specimen which did not possess them in some degree. In the purest they are scarcely repulsive, in the dark brown they are very much so. When a decided smell of ordinary fish oil is perceived, the medicine may always be suspected. It is quite distinct from that peculiar to the cod liver oil. The taste of all, except the very finest varieties, is more or less acrid, and in the most impure is bitterish, and somewhat empyreumatic. The pale-yellow oil is now exclusively used for medicinal purposes. The sp. gr. at 72° F., as ascertained by Prof. Procter, varied from 0·915 to 0·9195,—the first being that of the *hake* oil, the second that of the *haddock*, while the sp. gr. of the purest oil from the common cod was 0·917. De Jongh found the sp. gr. at 63° F. of the pale 0·923, of the light brown 0·924, of the dark brown 0·929. The oil from the cod does not congeal at 14° F., though that of *G. carbonarius* and that of the livers of different species of Raja let fall at that temperature a solid fatty matter, supposed to be palmitin. Alcohol dissolves from 2·5 to 6 per cent., water from 0·637 to 1·28 per cent., of different varieties; the pale yielding least to these solvents. (*Journ. de Pharm.*, Jan. 1854, p. 39.) The official description is as follows: "A pale-yellow, thin, oily liquid, having a peculiar, slightly fishy, but not rancid odor, and a bland, slightly fishy taste. Specific gravity, 0·920 to 0·925 at 15° C. (59° F.). Scarcely soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide; also in 2·5 parts of acetic ether." *U. S.* "Specific gravity 0·920 to 0·930. Readily soluble in *ether* and *chloroform*, and slightly soluble in *alcohol* (90 per cent.)." *Br.*

The chemical composition of the glycerides in cod liver oil appears to be very complicated. As palmitic and stearic acids have been isolated, the occurrence of palmitin and stearin is certain. But the so-called "stearin" separating from cod liver oil on cooling contains but little true stearin, as the cod liver stearin has a very high iodine value (113·4, Heyerdahl; 94, Lewkowitsch). The glycerides of the lower fatty acids, such as acetic, butyric, valeric, and capric acids, stated by various authors to occur in cod liver oil, are, according to Salkowski and Steenbuch, secondary products due to the putrefaction of livers. The latest researches of Heyerdahl (*Cod Liver Oil and Chemistry*. P. Möller, London, 1895) give as present in the mixed fatty acids about 4 per cent. of palmitic acid, 20 per cent. of *jecoleic acid*, $C_{19}H_{36}O_2$, and 20 per cent. of *therapic acid*, $C_{17}H_{26}O_2$. Besides these the "stearin" contains some unknown unsaturated acid or acids. Heyerdahl states that in the fresh state cod liver oil contains no hydroxy-acids.

A characteristic constituent of cod liver oil is *cholesterol*, which can be isolated by saponifying the oil and exhausting the soap with ether. The quantity of cholesterol, according to Allen and Thomson, is from 0·46 to 1·32 per cent. By reaction with ammonia in distillation the oil yields a volatile alkaloid, *trimethylamine*, C_3H_9N, which has a strong pungent odor, recalling that of herring-pickle, of which the same alkaloid is an ingredient. No other official fatty oil yields a similar product. (See *A. J. P.*, xxiv. 343.) Messrs. Gautier have obtained from cod liver oil the leucomaines *butylamine*, *iso-amylamine*, *hexylamine*, and *dihydrolutidine*, and two fixed bases, *aselline* ($C_{25}H_{32}N_4$) and *morrhuine* ($C_{19}H_{27}N_3$). Aselline was found by its discoverer to be relatively feeble physiologically; morrhuine, of which about 2 milligrammes are believed to exist in a tablespoonful of ordinary cod liver oil, is affirmed to have the properties

of exciting the appetite and acting as a powerful diuretic and diaphoretic. Besides these bases, an acid containing nitrogen has been found. This acid, *morrhuic acid*, $C_9H_{13}NO_3$, is probably identical with De Jongh's *gaduine*. Some have been disposed to ascribe the virtues of cod liver oil to its iodine and bromine; but these are in too small proportion for much effect, and the oil has produced results which have never been obtained from iodine and bromine themselves. The presence of iodine cannot be detected by the usual tests. It is necessary to convert the oil into a soap, and to carbonize this, before it will give evidence of iodine. The proportion never exceeds 0·05 per cent., or 1 part in 2000, and it is by no means certain that iodine is always, if ever, present in pure oil. The proportion of iodine present has been recently investigated by E. C. Stanford (*Pharm. Journ.* [3], xiv. 353), who found it to be extremely minute, ranging from 0·00138 to 0·00433 per cent., with an average of 0·00322 per cent. The oil is capable of dissolving a larger proportion of iodine; and, if any specimen contain more than 0·05 per cent., there is reason to suspect that iodine has been added.

Tests of Purity. In consequence of the great demand for this oil, it has not unfrequently been adulterated with other fixed oils, and occasionally others have been fraudulently substituted for it. The importance, therefore, is obvious of ascertaining some mode of testing its purity and genuineness. The official tests are as follows. "If 1 drop of the Oil be dissolved in 20 drops of chloroform, and the solution shaken with 1 drop of sulphuric acid, the solution will acquire a violet-red tint, rapidly changing to rose-red and brownish yellow. If a glass rod, moistened with sulphuric acid, be drawn through a few drops of the oil, on a porcelain plate, a violet color will be produced. Cod Liver Oil should be only very slightly acid to litmus paper previously moistened with alcohol (limit of *free fatty acids*. When the Oil is allowed to stand for some time at 0° C. (32° F.), very little or no solid fat should separate (absence of *other fish oils*, and of *many vegetable oils*). If 2 or 3 drops of fuming nitric acid be allowed to flow alongside of 10 or 15 drops of the Oil, contained in a watch-glass, a red color will be produced at the point of contact. On stirring the mixture with a glass rod, this color becomes bright rose-red, soon changing to lemon-yellow (distinction from *seal oil*, which shows at first no change of color, and from *other fish oils*, which become at first blue, and afterwards brown and yellow)." *U. S.* "A drop of *sulphuric acid* added to a few drops of the Oil on a porcelain slab develops a violet coloration. When *nitric acid* is carefully poured into some of the Oil contained in a test-tube, a precipitate of coagulated albumen should be formed at the surface of contact of the two liquids. No solid fat should separate on exposure of the Oil for two hours to a temperature of 32° F. (0° C.)." *Br.* There is reason to believe that all the oils from the livers of the Gadidæ have analogous properties. They have been indiscriminately used; and upon the results of their employment is based, in part, the present reputation of the medicine. They may, therefore, be considered as in fact one oil, so far as their medicinal use is concerned. Unfortunately, chemistry has yet discovered no perfectly reliable test. The furthest it has gone is to point out certain reactions, which may be considered as evidences of the presence of biliary principles in the oil, thus indicating its hepatic origin. Among these probably the most characteristic is that of Hager and Salkowski, in which a drop of sulphuric acid, added to fresh cod liver oil, on a porcelain plate, causes a centrifugal movement in the oil, and gives rise to a fine violet color, soon passing into yellowish or brownish red. Sometimes, instead of assuming the violet hue, the color immediately becomes a clear red or a dark brownish red. This is said to be especially the case with those specimens of the oil which have been prepared by boiling the livers with water. Shark liver oil responds in like manner to the test of sulphuric acid, but is said to have the sp. gr. 0·866, which is much lower than that of any variety of the genuine oil. According to Kremel, fuming nitric acid causes instantly, when agitated with cod liver oil, a pinkish or rose-red color, which soon becomes brown, while no such effect is produced on other animal or vegetable oils. According to Winckler, the oil should afford the smell of herring-pickle when heated with potassa, lime, and ammonium chloride. But the most reliable tests are the sensible properties of odor and taste. If there be none of the peculiar shoe-leather smell and taste, or if a strong lamp-oil odor be perceptible, the oil may be suspected. Little of importance can be inferred from the color. Some have been disposed to prefer the dark offensive oil; but our own experience accords with that of those who have found the pale or light brown equally efficient; and for facility of administration and acceptability to the stomach the latter is greatly preferable. It is important that the oil should be secluded from the air, which effects a gradual change, no doubt impairing its efficiency. Hence the vessels containing it should be full; and it should be kept in bottles

well stopped, holding about the quantity generally wanted for use at one time, and not exposed to the action of sunlight.

Medical Properties and Uses. Cod liver oil has long been popularly employed in Northern Europe in *rheumatic* and *strumous diseases*. It was first brought to the notice of the profession generally by German practitioners, and had acquired great reputation on the Continent before it was used to any extent in Great Britain. At Manchester, in England, it was employed by the medical profession in the treatment of *chronic rheumatism* and *gout* as early as 1766; but it was not until the appearance of the treatise of Professor Bennett, of Edinburgh, in 1841, that it came into general notice in Great Britain and the United States. The diseases in which it has proved most efficient are *chronic rheumatism* and *gout*, and the various morbid affections connected with a scrofulous diathesis, such as *external glandular scrofula*, *diseases of the joints and spine*, *carious ulcers*, *tabes mesenterica*, *rickets*, and *phthisis*. It has been found useful also in *chronic cutaneous eruptions*, *lupus*, and *chronic pectoral complaints* not tuberculous, and may be employed with the hope of good in almost all chronic cases in which there is impaired assimilation and nutrition. In *pulmonary consumption* it is of supreme value. It is necessary, however, to persevere for four or six weeks before looking for any decidedly favorable results, though the change does often begin earlier.

As to its mode of action, there has been much difference of opinion. Some consider it merely a nutritive agent, having the advantage over other oleaginous substances of a readier entrance into the system and more easy assimilation. But we cannot agree with this opinion. Other oleaginous substances, certainly not less nutritious, have not been equally efficient, though taken in much larger quantities. If this be the true explanation, persons living chiefly on milk, which abounds in oil, or on fat pork, ought to show a special exemption from scrofulous complaints. The probability appears to us to be that, in consequence of some peculiar principle or principles it contains, it exercises a stimulant and alterative influence on the processes of assimilation and nutrition, thereby aiding in the production of healthy tissue.

The dose is a tablespoonful (14·7 C.c.) three or four times a day for adults, a teaspoonful (3·7 C.c.) repeated as frequently for children, which may be gradually increased as the stomach will permit, and continued for a long time. It may be taken alone or mixed with some vehicle calculated to conceal its taste and obviate nausea. For this purpose recourse may be had to any of the aromatic waters, to the aromatic tinctures, as the tincture of orange-peel, diluted with water, or to a bitter infusion, as that of quassia. It may be given floating on the vehicle, or mixed with it by means of gum or the yolk of egg, with sugar, in the form of an emulsion. Perhaps the best vehicle, when not contra-indicated, is the froth of porter. Let a tablespoonful of porter be put into the bottom of a glass, upon the surface of this the oil, and over all some of the froth of the porter. A small piece of orange-peel may be chewed before and after taking the medicine.* Various other methods have been adopted to conceal or correct the taste and favor administration. Common salt has been recommended; but nothing, perhaps, so effectually destroys the taste as oil of bitter almond, of which one part will answer for 200 parts of the oil. A good plan is to shake strongly, in a flask, one measure of the oil with from one to two of bitter almond water, according to the degree of offensiveness, and to separate the liquids after they have been allowed to stand for twenty-four hours. The oil should be filtered if not quite clear. The medicine has sometimes also been given in capsules. M. Dufourmantel prepares a jelly by dissolving half a drachm of ichthyocolla in as little hot water as possible, and then gradually mixing with it a fluidounce of the oil with four drops of the oil of anise, taking care not to exceed the heat of 75° F. (*Journ. de Pharm.*, Juin, 1864, p. 72.) M. Bouchut incorporates the oil with wheat flour, and has this made into bread, which, he says, is in no degree disagreeable. (*N. R.*, Oct. 1873, pl. 522.)† The oil is sometimes applied externally by friction, and in cases of *ascarides* or *lumbricoides* is injected into the rectum. It has been recommended locally in *chronic articular affections*, in various *chronic cutaneous eruptions*, and in *opacity of the cornea* after the subsidence of inflammation. In the last-mentioned affection, one or two drops of the oil are applied by means of a pencil to the cornea,

* The following is Carlo Pavesi's formula for deodorized cod liver oil. Cod liver oil 1000 parts, ground roasted coffee 50 parts, animal charcoal 25 parts. Place the ingredients in a flask, which is to be well closed, and digest on a water-bath during the space of one hour; then set it aside for three days, occasionally shaking the contents, and filter. This preparation has a peculiar coffee flavor, and is quite pleasant to take, the only objection being the liability to cultivate in the patient a distaste for drinking coffee as a beverage. (*N. R.*, Jan. 1876.)

† *Phosphorized cod liver oil* may be made by dissolving one grain of phosphorus in four fluidounces of cod liver oil.

and diluted, if found too stimulating, with olive or almond oil.* It is often advantageously combined with lime salts, especially in *rickets*.†

The *olein* of cod liver oil has been recommended by Dr. Arthur Leared, when the oil itself disagrees with the stomach. He has found it to produce the same remedial effects, and to be borne much better. It may be given in the same dose. A *solution of quinine in the oil* may be made by heating the freshly precipitated alkaloid with the oil, in the proportion of two grains to a fluidounce, by means of a water-bath, until the mixture becomes quite clear.

OLEUM MYRCIÆ. U. S. Oil of Myrcia. [Oil of Bay.]

(Ō'LḘ-ŬM MŸR'CI-Æ.)

"A volatile oil distilled from the leaves of Myrcia acris, De Candolle (nat. ord. Myrtaceæ)." *U. S.*

This oil has been admitted to the Pharmacopœia as an ingredient of Spiritus Myrciæ, or bay rum. It is usually imported, although occasionally distilled in this country. The commercial oil is a mixture of both heavy and light oils, as Mr. G. M. Beringer found the specific gravity of two samples of undoubted purity to be 0·975 and 0·994. (*A. J. P.*, 1887, 286.) Mittmann (*Arch. der Pharm.*, 1889, 529) reported the following constituents: 1, *pinene;* 2, possibly *dipentene;* 3, a polyterpene, probably *diterpene* (insoluble in alcohol); these three in small quantity only; 4, *eugenol*, the chief constituent; and, 5, *methyl-eugenol*, in smaller quantity. It has since been examined (March, 1895) by Drs. Power and Kleber, who state that it contains from 60 to 65 per cent. of phenols, of which two were identified: *eugenol*, $C_{10}H_{12}O_2$, and *chavicol*, $C_9H_{10}O$; two phenol esters, *methyl-eugenol*, $C_{11}H_{14}O_2$, and *methyl-chavicol*, $C_{10}H_{12}O$; *phellandrene* and a newly discovered terpene which they name *myrcene;* and *citral*, $C_{10}H_{16}O$. (*Pharm. Rund.*, 1895, 60.) The oil is officially described as "a yellow or brownish-yellow liquid, having an aromatic, somewhat clove-like odor, and a pungent, spicy taste. Specific gravity, 0·975 to 0·990 at 15° C. (59° F.). With an equal volume of alcohol, glacial acetic acid, or carbon disulphide, it yields slightly turbid solutions. The alcoholic solution is slightly acid to litmus paper. When mixed with an equal volume of a concentrated solution of sodium hydrate, it forms a semi-solid mass. If 2 drops of the Oil be dissolved in 4 C.c. of alcohol, and a drop of ferric chloride test-solution be added, a light-green color will be produced; and if the same test be made with a drop of diluted ferric chloride test-solution, prepared by diluting the test-solution with four times its volume of water, a light-bluish coloration will be produced, which soon disappears. If to 3 drops of the Oil, contained in a small test-tube, 3 drops of concentrated sulphuric acid be added, and, after the tube has been corked, the mixture be allowed to stand for half an hour, a resinous mass will be obtained. On adding to this mass 4 C.c. of diluted alcohol, vigorously shaking the mixture, and gradually heating to the boiling point, the liquid should remain nearly colorless, and should not acquire a red or purplish-red color (distinction from *oil of pimenta* and *oil of cloves*). If 1 C.c. of the Oil be shaken with 20 C.c. of hot water, the water should not give more than a scarcely perceptible acid reaction with litmus paper. If, after cooling, the liquid be passed through a wet filter, the clear filtrate should produce, with a drop of ferric chloride test-solution, only a transient grayish-green, but not a blue or violet, color (absence of *carbolic acid*)." *U. S.* Oil of bay is not used internally.

OLEUM MYRISTICÆ. U. S., Br. Oil of Nutmeg.

(Ō'LḘ-ŬM MŸ-RĬS'TI-ÇÆ.)

"A volatile oil distilled from Nutmeg." *U. S.* "The oil distilled from nutmeg." *Br.*

Volatile oil of Nutmeg; Oleum Nucistæ Æthereum; Essence de Muscades, *Fr.;* Aetherisches Muskatöl, *G.*

This oil is obtained from powdered nutmegs by distillation with water. A better method,

* *Cod Liver Oil and Ferrous Iodide.* The following formula is that of a commission appointed by the Netherlands Pharmaceutical Society. Iodine 1 part; Pulverized Iron 1 part; Pale Cod Liver Oil 80 parts. Triturate the pulverized iron in a mortar with the iodine and one-fourth of the oil, and heat the mixture in a water-bath, with constant stirring, until the brown color of the iodine has entirely disappeared and given place to a deep purple color, showing that the ferrous iodide has been formed and dissolved. Then add the remainder of the oil, mix carefully, and, after standing, decant into dry bottles, which are to be completely filled. (*N. R.*, Aug. 1876.)

† *Cod Liver Oil with Lactophosphate of Lime.* Take of Cod Liver Oil, Oj; Oil of Bitter Almond, Oil of Peppermint, Oil of Wintergreen, each, gtt. x; Powdered Gum Arabic, ℥iv; Powdered Sugar, ℥vi; Solution of Lactophosphate of Lime (℥i to f℥i), f℥viss; Lime Water, f℥viss. Mix the gum and sugar in a capacious mortar, and make a smooth mucilage with the lime water and three ounces of the solution of lactophosphate of lime. Add the volatile oils to the cod liver oil, and gradually triturate them with the mucilage until a perfect emulsion is formed. Finally, add the rest of the solution of lactophosphate of lime, and mix thoroughly. Dose, from one-half to one fluidounce (15–30 C.c.). (J. T. Shinn, *A. J. P.*, March, 1873.)

according to M. J. Cloez, is to exhaust the powder with carbon disulphide or ether, distil off the solvent by means of a water-bath, and expose the butter-like residue to a current of steam, the vapor being conveyed into a refrigerated receiver, where it condenses. (*Journ. de Pharm.*, Fév. 1864.) Oil of nutmeg is colorless or of a pale straw color, limpid, lighter than water, soluble in an equal volume of glacial acetic acid, in alcohol and ether, with a neutral reaction, a pungent spicy taste, and a strong smell of nutmeg. The sp. gr. is stated differently at 0·920 and 0·948 (0·870 to 0·900 at 15° C. (59° F.), U. S.). "Specific gravity 0·870 to 0·910. The Oil forms a clear solution with its own volume of a mixture of equal parts of *absolute alcohol* and *alcohol* (90 per cent.). A little evaporated on a water-bath should not leave a residue which crystallizes on cooling (absence of the concrete oil of nutmeg)." *Br.* The mixture of volatile and fixed oils may be separated by agitation with water, one rising to the surface, the other sinking to the bottom. Upon standing, the latter deposits a crystalline solid, which was called by Playfair *myristin*. From its solution in alcohol he obtained it in extremely light crystalline scales, which, after repeated crystallization, had still the odor of nutmeg, were fusible at 31° C. (87·8° F.), soluble in the ordinary menstrua of substances of the same class, and, as just said, insoluble in water. By glacial acetic acid it was first colored red. (*P. J. Tr.*, March, 1874, 714.) It was identified as the glyceride of myristic acid, $C_{14}H_{28}O_2$, and had, therefore, the formula $C_3H_5(C_{14}H_{27}O_2)_3$. The essential oil, which has the sp. gr. 0·870–0·900, consists chiefly of pinene with probably some dipentene, also *myristicol*, $C_{10}H_{16}O$, and *myristicin*, $C_{12}H_{14}O_3$. (*Power's Catalogue of Essential Oils*, 1894.) Semmler (*Ber. Chem. Ges.*, 1890, 1803) examined an oil of nutmeg of sp. gr. 0·8611 which contained only terpenes: these boiled at about 50° C. under a pressure of 8 Mm. The oil may be used for the same purposes as nutmeg, in the dose of five or ten drops (0·3 or 0·6 C.c.), but is not often employed.

OLEUM OLIVÆ. U. S., Br. Olive Oil.

(Ō'LḘ-ŬM Ǫ-LĪ'VÆ.)

"A fixed oil expressed from the ripe fruit of Olea europæa, Linné (nat. ord. Oleaceæ)." *U. S.* "The oil expressed from the ripe fruit of Olea europæa (Linn.)." *Br.*

Oleum Olivarum, *P. G.;* Sweet Oil; Huile d'Olive, *Fr.;* Olivenöl, *G.;* Olio delle Olive, *It.;* Aceite de Olivas, *Sp.*

Olea europæa. L. *Sp. Pl.* (1753) 8. Willd. *Sp. Plant.* i. 44; *B. & T.* 172. This valuable tree is usually from fifteen to twenty feet in height, though sometimes much larger, especially in Greece and the Levant. It has a solid, erect, unequal stem, with numerous straight branches, covered with a grayish bark. The leaves, which stand opposite to each other on short footstalks, are evergreen, firm, lanceolate, entire, two or three inches in length, with the edges somewhat reverted, smooth and of a dark green color on their upper surface, whitish and almost silvery beneath. The flowers are small, whitish, and disposed in opposite axillary clusters, about half as long as the leaves, and accompanied with small, obtuse, hoary bracts. The fruit, or olive, is a smooth, oval drupe, greenish at first, but of a deep violet color when ripe, with a fleshy pericarp, and a very hard nut of a similar shape. Clusters of not less than thirty flowers yield only two or three ripe olives.

The olive-tree, though believed by some to have been originally from the Levant, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the south of France, and Italy. It begins to bear fruit after the second year, is in full bearing at six years, and continues to flourish for a century. There are forty varieties, distinguished by the form of the leaves and the shape, color, and size of the fruit. The variety *longifolia* of Willdenow is said to be chiefly cultivated in Italy and the south of France, and the *latifolia* in Spain. The latter bears much larger fruit than the former; but the oil is less esteemed. The olive is largely cultivated in the north of Africa, especially in the vicinity of Tunis, and considerable quantities of the oil are exported from that city. (*P. J. Tr.*, Sept. 1873, 204.) The tree has been introduced into South Australia, and will probably become of commercial importance there.

Olives are especially cultivated in Spain in the district of Cadiz. Two classes are produced, the one known as the Queen olive, a large olive, which is mostly exported to the United States; the other the Manzanillo, or small olive, which is chiefly consumed in Spain, South America, and Cuba. In the last decade the olive has been cultivated on a large scale very successfully in California,* both for the obtaining of the olive oil and also for the production of pickled

* The cultivation of the olive in California is said to have been very profitable, former growers reporting four hundred dollars per acre as a common yield of the olive orchard for the season; at this writing (1899) there is much

olives. The ordinary olive of commerce is pickled before ripening; the ripe olive as put up in California is dark, often almost blackish, very different in taste to the ordinary unripe pickled fruit, and is said to contain about 50 per cent. of olive oil, so that it affords an excellent method of administering fat.

The leaves and bark of the olive-tree have an acrid and bitterish taste, and have been employed as substitutes for cinchona, though with no great success. Attention has been called, in France, to a hydro-alcoholic extract of the leaves, as having considerable febrifuge powers. In the quantity of from ten to twenty grains daily, in divided doses, it has been found useful in preventing the hectic paroxysms. In hot countries, a substance resembling the gum-resins exudes spontaneously from the bark. It was thought by the ancients to possess useful medicinal properties, but is not now employed. Analyzed by Pelletier, it was found to contain resin, a little benzoic acid, and a peculiar principle analogous to gum, which has been named *olivile*. But the fruit is by far the most useful product. In the unripe state it is hard and insupportably acrid; but when macerated in water or an alkaline solution, and afterwards introduced into a solution of common salt, it loses these properties, and becomes a pleasant and highly esteemed article of diet. Mannite has been found in all parts of the tree while in vital activity, as in the green leaves and unripe fruit, but cannot be detected in the yellow fallen leaves or in the perfectly ripe fruit. (*A. J. P.*, 1866, p. 179.) The pericarp, or fleshy part of the ripe olive, abounds in a fixed oil, which constitutes its greatest value, and for which the tree is chiefly cultivated in Southern Europe. In the unripe olive a peculiar green substance, together with mannite, has been found by M. S. de Lutz, both of which disappear as the fruit ripens, being probably converted into oil, which now takes their place. (*Journ. de Pharm.*, Juin and Déc. 1862.) The olives ripen from November to March, and the oil is obtained by first bruising them in a mill and then submitting them to pressure. The product varies much, according to the state of the fruit and the circumstances of the process. The best, called *virgin oil*, is obtained from the fruit picked before perfect maturity, and immediately pressed. It is distinguished by its greenish hue. The common oil used for culinary purposes and in the manufacture of the finest soaps is procured from very ripe olives, or from the pulp of those which have yielded the virgin oil. In the latter case the pulp is thrown into boiling water, and the oil removed as it rises. An inferior kind, employed in the arts, especially in the preparation of the coarser soaps, plasters, unguents, etc., is afforded by fruit which has been thrown into heaps, and allowed to ferment for several days, or by the marc left after the expression of the finer kinds of oil, broken up, allowed to ferment, and again introduced into the press. The remarks made under the head of Oleum Myristicæ in relation to the extraction of that oil by means of solvents are applicable also to olive oil.

Olive oil is imported in glass bottles, or in flasks surrounded by a kind of net-work of grass and usually called Florence flasks. The best comes from the south of France, where most care is exercised in the choice of the fruit.

Properties. The pure oil is an unctuous liquid, of a pale-yellow or greenish-yellow color, with scarcely any smell, and a bland, slightly sweetish taste. Its sp. gr. is 0·9153 (0·915 to 0·918, *U. S.*). It is soluble in chloroform, carbon disulphide, and in twice its volume of ether, but is only partially soluble in alcohol, at least unless this liquid be in very large proportion.

The concrete portion, which separates at a freezing temperature, consists chiefly of the glyceride of *palmitic acid*, $C_{16}H_{32}O_2$, together with the corresponding compound of *arachic acid*, $C_{20}H_{40}O_2$ (stearic acid is stated by Hehner and Mitchell to be absent entirely); the liquid portion is essentially olein, $C_3H_5(O.C_{18}H_{33}O)_3$, with a small amount (seven parts for ninety-three of olein) of the glyceride of the less saturated linolic acid. According to Braconnot, the oil contains 72 per cent. of olein and 28 of palmitin. A small quantity of *cholesterin*, $C_{26}H_{44}O$, has also been found in the oil. Olive oil is solidified by nitrous acid and mercuric nitrate, and converted into a peculiar fatty substance, called *elaidin*. The olein of all oils which have not the drying property undergoes the same change when acted on by nitrous acid.

The greenish color is owing to the presence of a trace of chlorophyll, and a trace of cholesterin is also extracted by repeated agitation with glacial acetic acid.*

Olive oil, when exposed to the air, is apt to become rancid, acquiring a disagreeable smell, a

complaint that the culture is being overdone. There is a large number of different varieties of the olive. J. L. Howland, of Pomona, reports the following percentage of oil yielded by each variety as the result of two years' test: Pendulina, 21; Rubra, 18½; Oblonga, 18; Mission, 17$\frac{9}{10}$; Uvaria, 17½; Nevadillo Blanco, 16½; Columella, 16½; Precox, 14; Picholine, 10; Manzanillo, 8½. For further information concerning the subject the reader is referred to the various Proceedings of the California State Convention of Olive Growers.

* For discussion of the spectra of olive oil, see *P. J. Tr.*, 3d series, vii. 22, 110.

sharp taste, and a thicker consistence; it also loses its color; and the change is promoted by heat. It is officially tested as follows. "When cooled to about 10° C. (50° F.), the Oil begins to become somewhat cloudy from the separation of crystalline particles, and at 0° C. (32° F.) it forms a whitish, granular mass. If 10 C.c. of the Oil be shaken frequently, during two hours, with a freshly prepared solution of 1 Gm. of mercury in 3 C.c. of nitric acid, a perfectly solid mass of a pale straw color will be obtained. If 6 Gm. of the Oil be thoroughly shaken, in a test-tube, for about two minutes, with a mixture of 1·5 Gm. of nitric acid and 0·5 Gm. of water, then heated in a bath of boiling water for not more than fifteen minutes, the Oil should retain a light yellow color, not becoming orange or reddish-brown, and, after standing at the ordinary temperature for about twelve hours, it should form a perfectly solid, light yellowish mass (absence of appreciable quantities of *cotton seed oil* and *most other seed oils*). If 5 C.c. of the Oil be thoroughly shaken, in a test-tube, with 5 C.c. of an alcoholic solution of silver nitrate (prepared by dissolving 0·1 Gm. of silver nitrate in 10 C.c. of deodorized alcohol, and adding 2 drops of nitric acid), and the mixture be heated for about five minutes in a water-bath, the Oil should retain its original, pale yellow color, not becoming reddish or brown, nor should any dark color be produced at the line of contact of the two liquids (absence of more than about 5 per cent. of *cotton seed oil* and of *many other foreign oils*). If 30 C.c. of the Oil be saponified by heating with 20 C.c. of alcohol and 5 Gm. of potassa, the liquid then diluted with 200 C.c. of water, and freed from alcohol by boiling, on supersaturating the solution with diluted sulphuric acid, the fatty acids will form a layer on the surface. If these be separated as far as possible, free from water, and filtered, 5 C.c. of the clear filtrate, when shaken, in a test-tube, with 5 C.c. of concentrated hydrochloric acid, should not color the latter green; and, on the subsequent addition of about 0·5 Gm. of sugar, and again shaking the mixture, no violet or crimson tint should be produced in the acid layer within fifteen minutes (absence of *sesamum oil*)." *U. S.* "At 50° F. (10° C.) it is liable to become of a pasty consistence, and at 32° F. (0° C.) to form a nearly solid granular mass. If 10 cubic centimetres of the Oil be shaken with 2 cubic centimetres of a reagent prepared by dissolving 1 gramme of *silver nitrate* in 100 cubic centimetres of *absolute alcohol*, with the addition of 20 cubic centimetres of *ether* and one drop of *nitric acid*, no blackening should occur when the mixture is heated on a water-bath for ten minutes (absence of cotton-seed oil)." *Br.* It is frequently adulterated with the cheaper fixed oils, especially with that of poppies; but the adulteration may be detected by reducing the temperature to the freezing point. As other oils are less readily congealed than is the olive oil, the degree of its purity will be indicated by the degree of concretion. Another mode has been indicated by M. Poutet, founded on the property possessed by mercuric nitrate of solidifying the oil of olives, without a similar influence upon other oils. Six parts of mercury are dissolved at a low temperature in seven and a half parts of nitric acid of the sp. gr. 1·35, and this solution is mixed with the suspected oil in the proportion of one part to twelve, the mixture being occasionally shaken. If the oil be pure, it will be converted after some hours into a yellow solid mass; if it contain a minute proportion, even so small as a twentieth, of poppy or cotton-seed oil, the resulting mass will be much less firm; and a tenth will prevent a greater degree of consistence than oils usually acquire when they concrete by cold. Lewkowitsch (*Chemical Analysis of Oils, Fats, and Waxes*, 2d ed., 1898, 462) says that the color reactions proposed by various authors are altogether unreliable and yield no definite results, with the exception of the color-test (Baudoin's test, see *Oleum Sesami*) for sesame oil and perhaps Bechi's and Milliau's for cotton-seed oil (see below). For a method of detecting the *oil of arachis* (*ground-nut oil*) in olive oil, see *Journ. de Pharm.*, Janv. 1872, 48. Immense quantities of lard oil and cotton-seed oil* are exported from this country to France and employed in the adulteration of olive oil. Bechi's test for ascertaining the admixture of cotton-seed oil with olive oil has received the unanimous approval of the Commission of Florence after most exhaustive experiments, and is as follows. One grain of silver nitrate is dissolved in fifteen minims (or 1 C.c.) of water, and six and a half fluidounces (or 200 C.c.) of alcohol are added. Two fluidounces (or 60 C.c) of ether may be added to render the solution more easily miscible with the oil, but it is not absolutely necessary. A solution of eighty-five parts of amylic alcohol and fifteen parts of rape-seed oil is prepared. These reagents should not be kept on hand any length of time. To ten C.c. of the oil to be

* Of 140,840 barrels of cotton-seed oil, or nearly 6,000,000 gallons, shipped from New Orleans during the year 1880, 88 per cent. was exported on orders from Europe to Mediterranean and French ports, and one-half of this to Italy. This is more than the entire olive oil production of France, and one-fifth that of Italy itself. The United States imports only one-tenth of this amount of olive oil so called. (*A. J. P.*, July, 1881, 343.)

examined one C.c. of the solution of silver nitrate is added, and then from eight to ten C.c. of the amylic alcohol reagent; the mixture is agitated strongly, and heated on a water-bath for five or ten minutes. In the case of pure oils the color is unaltered by the addition of the reagents; if cotton-seed oil be present, a brownish color or turbidity, varying from a light brown to a deep maroon or black (according to the extent of the adulteration), will be produced. (*A. J. P.*, 1887.) Milliau's test is a modification of the foregoing. If the fatty acids instead of the oil itself are treated with the same reagents, we get the same reduction of the silver salts and the same brown color as in the Bechi test.

Medical Properties and Uses. Olive oil is nutritious and mildly laxative, and is occasionally given as a feeble purgative in cases of irritable intestines. Taken into the stomach in large quantities, it serves to involve acrid and poisonous substances and mitigate their action. It has also been recommended as a remedy for *worms*, and is a very common ingredient in laxative enemata. The value of large doses of olive oil in the treatment of *gall-stones*, as originally suggested by Dr. Kennedy, has received much confirmation, and the experiments of Rosenberg go to show that the remedy does increase not only the amount but also the fluidity of the bile. From six to seven ounces of it may be given in from four to eight portions, during not less than three hours, in aromatized emulsion. Externally applied, it is useful in relaxing the skin and in sheathing irritated surfaces from the action of the air; and it is much employed as a vehicle or diluent of more active substances. But the most extensive use of olive oil is in pharmacy, as a constituent of liniments, ointments, cerates, and plasters. The dose as a laxative is from one to two fluidounces (30–60 C.c.).

OLEUM PHOSPHORATUM. U. S., Br. Phosphorated Oil.

(Ō'LḘ-ŬM PHŎS-PHO-RĀ'TŬM.)

Huile phosphorée, Liniment phosphoré, *Fr.*; Phosphorhaltiges Oel, *G.*

"Phosphorus, *one gramme* [or 15·5 grains]; Expressed Oil of Almond, Ether, each, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 231 grains]. Introduce a *sufficient quantity* of Expressed Oil of Almond into a flask, heat it on a sand-bath to 250° C. (482° F.), and keep it at that temperature for fifteen minutes. Then allow it to cool, and filter it. Put *ninety grammes* [or 3 ounces av., 76 grains] of the filtered Oil together with the Phosphorus, previously well dried by filtering paper, into a dry, tared bottle capable of holding about *one hundred and twenty cubic centimeters* [or 4 fluidounces, 28 minims], insert the stopper, and heat the bottle in a water-bath until the Phosphorus melts. Then agitate it until the Phosphorus is dissolved, allow it to cool, add enough Ether to make the mixture weigh *one hundred grammes* [or 3 ounces av., 231 grains], and agitate it again. Lastly, transfer the solution to small glass-stoppered vials, which should be completely filled and kept in a cool and dark place." *U. S.*

"Heat Almond Oil in a porcelain dish to about 300° F. (149° C.), and keep it at this temperature for about fifteen minutes, then let it cool, and filter it through paper. Put ninety-nine parts by weight into a stoppered bottle, capable of holding rather more than this quantity, and add to it one part by weight of dry Phosphorus. Immerse the bottle in hot water until the mixture has acquired the temperature of 180° F. (82·2° C.), removing the stopper two or three times to allow the escape of expanded air; then shake until the Phosphorus is entirely dissolved." *Br.*

The U. S. process does not differ essentially from that of the Br. Pharm. Both the U. S. P. and British oils are one-per-cent. solutions; the British formerly contained but 0·75 per cent.* The object of heating the oil is to expel air and traces of water, which would aid in oxidizing the phosphorus. The ether not only assists in the preservation of the finished preparation, but is also of use in rendering the oil less disagreeable to the taste. Dr. E. R. Squibb passes a current of carbonic acid gas through the oil contained in the bottle that it is to be kept in, to expel the air and prevent oxidation.

* It is often desirable to be acquainted with the degree of solubility of phosphorus in the different fixed oils in ordinary use, in reference to its exhibition as medicine. The following list is taken from the *Journal de Pharmacie* (Fév. 1869, p. 94), where it is given on the authority of M. C. Merc. The oils of sweet almond, of olives, of sesamum, and of ground-nuts will retain, at common temperatures, $\frac{1}{80}$ of their weight of phosphorus. It may even descend to $\frac{1}{78}$ for almond and ground-nut oils; but it is not prudent, in practice, to keep too near the limits of saturation. The oils of colza and flaxseed, brown cod-liver oil, and neat's-foot oil, retained $\frac{1}{70}$ of their weight, even after eight days' exposure in a cellar. Castor oil is far removed from these figures, 105 parts of it being required to dissolve one part of phosphorus. The author has observed no sensible difference in the dissolving power of overheated and not overheated oils.

This is a clear and colorless or but slightly colored oil, not phosphorescent in the dark, and having the odor and taste of phosphorus quite distinctly. "It should be perfectly free from any particles of undissolved phosphorus." *U. S.* It may be administered in the form of an emulsion, like the official almond emulsion, and flavored with oil of bitter almond, or preferably in capsules: each minim contains about $\frac{1}{115}$ of a grain of phosphorus. Dose of the U. S. solution, from three to five minims (0·18–0·3 C.c.).

OLEUM PICIS LIQUIDÆ. U. S. Oil of Tar.

(Ō'LḘ-ŬM PĪ'CĬS LĬQ'UḬ-DÆ—lik'wę-dē.)

"A volatile oil distilled from Tar." *U. S.*

Huile volatile de Goudron, *Fr.;* Theeröl, *G.*

This oil is prepared by distilling wood-tar; the residue left in the still being known as pitch. It represents thoroughly the medicinal properties of tar, and is preferable on account of its less offensive taste. (See *Pix Liquida.*) It is officially described as "an almost colorless liquid when freshly distilled, but soon acquiring a dark reddish-brown color, and having a strong, tarry odor and taste. Specific gravity, about 0·970 at 15° C. (59° F.). It is readily soluble in alcohol, the solution being acid to litmus paper." *U. S.* The dose is from one to five minims, administered in capsule or in emulsion.

OLEUM PIMENTÆ. U. S., Br. Oil of Pimenta. [Oil of Allspice.]

(Ō'LḘ-ŬM PĪ-MĔN'TÆ.)

"A volatile oil distilled from Pimenta." *U. S.* "The oil distilled from pimento." *Br.*

Oil of Pimento; Essence de Piment de la Jamaïque, *Fr.;* Nelkenpfefferöl, *G.*

The berries yield from 1 to more than 4 per cent. of the volatile oil, which as found in commerce is brownish red, and has the odor and taste of pimenta, though warmer and more pungent. It has a slightly acid reaction. It is said, when freshly distilled, to be colorless or yellowish. Nitric acid reddens it. Its sp. gr. is stated at 1·021, but varies (1·045 to 1·055, *U. S.*). It is readily soluble in alcohol. With a concentrated solution of potassa it forms a semi-solid mass. According to the U. S. P. 1890, "with an equal volume of alcohol it forms a clear solution, which is slightly acid to litmus paper. It also forms a clear solution with an equal volume of glacial acetic acid, and a nearly clear solution with an equal volume of carbon disulphide. When mixed with an equal volume of a concentrated solution of sodium hydrate, it forms a semi-solid mass. If 2 drops of the Oil be dissolved in 4 C.c. of alcohol, and a drop of ferric chloride test-solution added, a bright green color will be produced; and if the same tests be made with a drop of diluted ferric chloride test-solution, prepared by diluting the test-solution with four times its volume of water, a blue color will be produced, changing to green, and soon becoming yellow. If 1 C.c. of the Oil be shaken with 20 C.c. of hot water, the water should not give more than a scarcely perceptible acid reaction with litmus paper. If, after cooling, the liquid be passed through a wet filter, the clear filtrate should produce, with a drop of ferric chloride test-solution, only a transient grayish-green, but not a blue or violet, color (absence of *carbolic acid*)." "Yellow or yellowish-red when recently distilled, but gradually becomes darker. It has the odor and taste of pimento. Specific gravity not below 1·040. It should be converted into a semi-solid mass when shaken with an equal volume of *strong solution of ammonia.*" *Br.* It consists, like oil of cloves, of two distinct oils, a lighter and a heavier, the former of which comes over first in distillation. They may be separated by distilling the oil from caustic potassa. The light oil comes over, and the heavy remains combined with the potassa. The latter may be obtained by distilling the residue with sulphuric acid. The light oil is lighter than water, and is a sesquiterpene, $C_{15}H_{24}$; the heavy has the acid property of forming crystalline compounds with the alkalies. They are analogous to the light and heavy oils of cloves. Indeed, the heavy has been found to be identical with the eugenol of oil of cloves. (See *Oleum Caryophylli.*) L. C. Pettit (*A. J. P.*, 1880, 443) found 61 per cent. of eugenol in the oil. Oil of pimenta is given for the same purposes as are the other stimulant aromatic oils. The dose is from three to six drops (0·18–0·36 C.c.).

OLEUM PINI. Br. Oil of Pine.

(Ō'LḘ-ŬM PĪ'NĪ.)

"The oil distilled from the fresh leaves of Pinus Pumilio, Haenke." *Br.*

The British Pharmacopœia 1898 replaced fir-wool oil by making oil of pine official. This was largely due to the investigations of J. C. Umney (*P. J. Tr.*, 1895, 161, 173, 542), who

found that the *Pinus Pumilio* (*Mountain Pine*) furnished an oil of fairly constant character and superior to that from the *Pinus Sylvestris* (*Scotch Fir*) of the Br. Ph. 1885. It is described as "Colorless or nearly so, with a pleasant aromatic odor and pungent taste. Specific gravity 0·865 to 0·870. It should rotate the plane of a ray of polarized light from 5° to 10° to the left at 60° F. (15·5° C.) in a tube 100 millimetres long. Not more than 10 per cent. should distil below 329° F. (165° C.)." *Br.* It resinifies on exposure, and in medicinal qualities resembles turpentine, but is milder. An investigation of fir-wool oil by Schimmel & Co. (*Semi-Annual Report*, April, 1893) shows that this oil contains *dextro-pinene*, *sylvestrene*, *sesquiterpene*, and *bornyl acetate*. It is supposed that the pine oil owes its odor to the presence of this last constituent, the acetic ester of borneol, which is ordinarily present to the amount of about 3·5 per cent., although Schimmel & Co. (*Report* for Oct. 1897) found in a sample of American fir oil as much as 12·1 per cent. It has been used internally in the treatment of *chronic rheumatism* in doses of from ten to twenty drops four times a day, but it is especially employed for the purposes of inhalation. The leaves of the *Pinus sylvestris*, with those of other European firs and pines, by pounding are converted into a fibrous substance, known as *fir-wool* (*Fichtenwolle*), which is much used in Germany as a local application in *chronic rheumatism*, the affected part being enveloped in a thick batting of the fir-wool, which is also sometimes made into clothing for rheumatic persons. An extract of the leaves is also sold under the name of *fir-wool extract*, for use in rheumatism.

OLEUM RICINI. U. S., Br. Castor Oil.

(Ō'LḘ-ŬM RĬÇ'Ị-NĪ.)

"A fixed oil expressed from the seed of Ricinus communis, Linné (nat. ord. Euphorbiaceæ)." *U. S.* "The oil expressed from the seeds of Ricinus communis." *Br.*

Huile de Ricin, *Fr.;* Ricinusöl, *G.;* Olio di Ricino, *It.;* Oleum Palmæ Christi; Aceite de Ricino, *Sp.*

Ricinus communis. Willd. *Sp. Plant.* iv. 564. The castor oil plant, or *palma Christi*, attains in the East Indies and Africa the character of a tree, and rises sometimes thirty or forty feet. In the temperate latitudes of North America and Europe it is annual; though M. Achille Richard saw in the south of France, in the vicinity of Nice, on the sea-coast, a small wood consisting entirely of what he supposed to be this species of Ricinus.* The following description applies to the plant as cultivated in cool latitudes. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate, peltate, six to eleven palmately lobed, the lobes acute or acuminate and serrate, smooth on both sides, and of a bluish-green color. The flowers are monœcious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the male flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments, and encloses numerous stamens, united into fasciculi at their base. In the female the calyx has three or five narrow lanceolate segments; and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish, glaucous capsule, with three projecting sides, covered with tough spines, and divided into three cells, each containing one seed, which is expelled by the bursting of the capsule. This species of Ricinus is a native of the East Indies and Northern Africa, naturalized in the West Indies, and cultivated in various parts of the world, in few countries more largely than in the Middle and Western United States. The flowers appear in July, and the seeds ripen successively in August and September. A decoction of the leaves is said to be employed effectively as a local galactagogue, and an infusion has been given internally for a similar purpose. (*London Lancet*, Dec. 1859.)

1. The Seeds. These are about as large as a small bean, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash color, marbled with reddish brown spots and veins. At one end of the seed is a small yellowish tubercle, from which an obscure longitudinal ridge proceeds to the opposite extremity, dividing the side upon which it is situated into two flattish surfaces. In its general appearance the seed is thought to resemble the insect called the *tick*, the Latin name of which has been adopted as the generic title of the plant. Its variegated color depends upon a very thin pellicle closely investing a

* While at Montpellier, in France, in the spring of 1861, Dr. Geo. B. Wood was assured by Dr. Martius, professor of botany in the university of that city, that the species seen by Richard was not the *Ricinus communis*, but the *Ricinus africanus*, also that all the plants of the genus Ricinus growing wild on the borders of the Mediterranean were the *R. africanus*.

hard, brittle, blackish, tasteless, easily separated shell, within which is the kernel, highly oleaginous, of a white color, and of a sweetish taste succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. In 100 parts Geiger found, exclusive of moisture, 23·82 parts of envelope, and 69·09 of kernel. These 69·09 parts contained 46·19 of fixed oil, 2·40 of gum, 20·00 of starch and lignin, and 0·50 of albumen. Mr. Henry Bower could find no starch, but separated from the seeds an albuminoid principle, which acted with amygdalin and water like emulsin, producing the odor of oil of bitter almond, though in a less degree. (*A. J. P.*, xxvi. 208.) It is highly probable that it is this principle which, acting as a ferment on the oily matter of the seeds, gives rise to changes in its nature which render them rancid. Mr. G. J. Scattergood found the odor of castor oil to be developed in the beans when bruised with water, and much more powerfully in those long kept than in the fresh. The water distilled from the seeds has a peculiar nauseous odor, quite distinct from that of the oil. (*Ibid.*, xxvii. 207.)*

Taken internally the seeds are powerfully cathartic, and often emetic. Two are sufficient to purge with great violence, and three have produced fatal gastro-enteritis in the adult. After expression of the oil, and treatment with pure alcohol, M. Calloud found the residue to be powerfully emetic in the quantity of 30 grains, taken in two doses. (*Journ. de Pharm.*, 3e sér., xiv. 190.) According to Guibourt, the toxic property pervades the whole kernel, the integuments being inert. The experiments of Mr. Scattergood, who found that the water distilled from the seeds is emetic and cathartic, would seem to show that the active principle is volatile, but the researches of Stillmark indicate that it is an unformed ferment, *ricin*,† which is a so-called phytalbumose and has been obtained as a white amorphous powder, and is best dissolved in a 10-per-cent. salt solution. The aqueous solution of the pure ricin has a neutral reaction. It is a violent poison. E. L. Boerner (*A. J. P.*, 1876, p. 481) obtained butyric acid by macerating the exhausted marc of the seeds with water until decomposed.

2. The Oil. This may be extracted from the seeds in three ways: 1, by decoction; 2, by expression; 3, by the agency of alcohol or other solvent.

The process by decoction, which has been practised in the East and West Indies, consists in bruising the seeds, previously deprived of their husk, and then boiling them in water. The oil, rising to the surface, is skimmed or strained off, and afterwards again boiled with a small quantity of water to dissipate the acrid principle. The seeds, it is said, are sometimes roasted, to increase the product. But by a temperature much above 212° F. the oil is rendered brownish and acrid; and the same result takes place in the second boiling, if care is not taken to suspend the process soon after the water has been evaporated. Hence it happens that the West India oil has generally a brownish color, an acrid taste, and irritating properties.

The oil is obtained in this country by expression. The following, we have been informed, are the outlines of the process usually employed by those who prepare it on a large scale. The seeds, having been thoroughly cleansed from the dust and fragments of the capsules with which they are mixed, are conveyed into a shallow iron reservoir, where they are submitted to a gentle

* *Ricinine or Ricinia.* Professor Tuson announced the discovery in the seeds of a peculiar alkaloid, which he named *ricinine*. To obtain it, the crushed seeds are exhausted by successive portions of boiling water; the decoction is filtered through wet muslin; the filtered liquor is evaporated to dryness over a water-bath; the extract thus obtained is exhausted by boiling alcohol; the alcoholic solution is allowed to cool, then filtered to separate a little resinous matter, and lastly concentrated and permitted to stand. In the course of some hours, a mass of nearly white crystals is deposited, which when recrystallized from alcohol and decolorized by animal charcoal are the alkaloid in a pure state. Ricinine crystallizes in rectangular prisms and tables, has a feebly bitter taste, somewhat resembling that of bitter almonds, is fusible, and crystallizes on cooling, volatilizable unchanged, inflammable, soluble most readily in water and alcohol, and very slightly in ether or benzol. Heated with hydrate of potassa it evolves ammonia, and therefore contains nitrogen. It appears to combine with sulphuric, nitric, and hydrochloric acids. But a more accurate investigation is needed before it can be admitted to be undoubtedly a distinct and pure alkaloid. A minute quantity is said to be obtained from castor oil by shaking it with water, evaporating the liquid, treating the residue with boiling benzol, and allowing the solution to evaporate spontaneously. Professor Tuson does not claim for the new alkaloid the possession of purgative properties. Two grains given to a rabbit produced no observable effect. Prof. E. S. Wayne obtained from the leaves of *Ricinus communis* a substance apparently identical with Tuson's ricinine, but he does not consider it to be an alkaloid. (*A. J. P.*, 1874, p. 97.)

† *Ricin*, when given either hypodermically or by the mouth, produces violent inflammation of the gastro-intestinal tract, also of the mucous membrane of the biliary duct, and of the bladder and kidneys. Hence, probably, the jaundice and anuria which have been observed in some cases of poisoning by castor oil seeds. A substance very closely allied to, if not identical with, ricin, was also found in the croton oil seed. Though ricin, outside of the body at least, exerts a very peculiar action upon the blood, it seems to have very little influence upon the general system, and to act as a poison chiefly, if not solely, by its irritating influence on the alimentary tract. Ricin has been found by Berkley (*Medical Record*, xlix. 1896) to produce demonstrable changes in the protoplasm of the centric nerve-cells.

heat insufficient to scorch or decompose them, and not greater than can be readily borne by the hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful hydraulic press. A whitish oily liquid is thus obtained, which is transferred to clean iron boilers supplied with a considerable quantity of water. The mixture is boiled for some time, and, the impurities being skimmed off as they rise to the surface, a clear oil is at length left upon the top of the water, the mucilage and starch having been dissolved by this liquid, and the albumen coagulated by the heat. The latter ingredient forms a whitish layer between the oil and the water. The clear oil is now carefully removed; and the process is completed by boiling with a minute proportion of water, and continuing the application of heat till aqueous vapor ceases to rise, and till a small portion of the liquid, taken out in a vial, continues perfectly transparent when it cools. The effect of this last operation is to clarify the oil, and to render it less irritating by driving off the acrid volatile matter. But much care is requisite not to push the heat too far, as the oil then acquires a brownish hue and an acrid peppery taste. After the completion of the process, the oil is put into barrels and sent into the market. See article on the preparation of castor oil (*A. J. P.*, 1879, p. 481).* There is reason, however, to believe that much of the American oil is prepared by merely allowing it to stand for some time after expression, and then drawing off the supernatant liquid. One bushel of good seeds yields five or six quarts, or about 25 per cent., of the best oil. If not carefully prepared, it is apt to deposit a sediment upon standing; and the apothecary may find it necessary to filter it through coarse paper before dispensing it. Perhaps this may be owing to the plan just alluded to of purifying the oil by rest and decantation. We have been told that the oil in barrels usually deposits in cold weather a copious whitish sediment, which is redissolved when the temperature rises. A large proportion of the drug consumed in the eastern section of the Union has been derived, by the way of New Orleans, from Illinois and the neighboring States, where it has been at times so abundant that it has been used for burning in lamps and for lubricating machinery.†

The process for obtaining castor oil by means of alcohol has been practised in France; but the product is said to become rancid more speedily than that procured in the ordinary mode. Such a preparation has been employed in Italy, and is asserted to be less disagreeable to the taste, and more effective, than the common oil obtained by expression. According to M. Parola, an ethero-alcoholic extract and an ethereal or alcoholic tincture of the seeds operate in much smaller doses than the oil, and with less disposition to irritate the bowels or to cause vomiting. (See *Am. Journ. of Med. Sci.*, N. S., xiii. 143.)

Properties. Pure castor oil is a thick, viscid, colorless liquid, with little or no odor, and a mild though somewhat nauseous taste, followed by a slight sense of acrimony. As found in commerce it is often tinged with yellow and has an unpleasant smell; and parcels are sometimes, though rarely, met with of a brownish color and hot acrid taste. It does not readily congeal by cold. When exposed to the air it slowly thickens, without becoming opaque. "When exposed to the air in a thin layer, it slowly dries to a varnish-like film. When cooled to 0° C. (32° F.), it becomes turbid, with the separation of crystalline flakes, and at about —18° C. (—0·4° F.) it congeals to a yellowish mass. If 3 C.c. of the Oil be shaken for a few minutes with 3 C.c. of carbon disulphide and 1 C.c. of sulphuric acid, the mixture should not acquire a blackish-brown color (absence of *many foreign oils*)." *U. S.* It is heavier than most of the other fixed oils, its sp. gr. having been stated to be 0·969 at 55° F. (0·950 to 0·970 at 15° C., *U. S.*). It differs also from other fixed oils in being soluble in all proportions in cold absolute alcohol. "Soluble in an equal volume of alcohol, and, in all proportions, in absolute alcohol, or in gla-

* For a particular account of the mode of cultivating the castor oil plant and preparing the oil in the Western States, see a paper by Prof. Procter in *A. J. P.* (xxvii. 99).

† *Italian Castor Oil.* The castor oil plant is cultivated throughout Italy, but especially in the neighborhood of Verona, where the oil is prepared with great care and is remarkably free from the peculiar odor and taste which render this medicine so repulsive to many palates. As it is highly desirable, for certain purposes, that the oil should be as free from these properties as possible, though as a mere purgative perhaps less powerful when deprived of them, it is a point worthy of investigation, why it is that the Italian oil is superior to most if not all other commercial varieties of the oil in these respects. The following facts in relation to the mode of preparing the oil practised at Verona, published by Mr. H. Groves, of Florence, acquire on this account a special value. One point of importance is that the seeds are used fresh, as the oil rapidly becomes rancid in them when kept. Another fact is that the seeds are entirely deprived of their coating before being submitted to pressure. This is effected by passing them between two revolving wooden rollers, with a winnowing machine beneath; and, to secure the complete absence of integument, they are afterwards assorted by the hand, all being rejected which are not perfectly decorticated. They are then put into hempen bags, which are arranged in layers with a sheet of iron heated to 90° F. between them, so as to enable the oil to flow. Lastly, they are submitted to pressure in hydraulic presses. The oil which now flows is of the finest quality. An inferior kind is obtained by pressing the marc at a somewhat higher heat. (*P. J. Tr.*, Oct. 1866.)

cial acetic acid; also soluble, at 15° C. (59° F.), in 3 times its volume of a mixture of 19 volumes of alcohol and 1 volume of water (absence of more than about 5 per cent. of *most other fixed oils*). With an equal volume of benzin, it forms, at 15° C. (59° F.), a turbid mixture, but at 17° C. (62·6° F.) it yields a clear solution." *U. S.* "Specific gravity 0·950 to 0·970. Soluble in an equal volume of *absolute alcohol*, and in five times its volume of *alcohol* (90 per cent.). It dries slowly to a varnish when exposed to the air in a thin layer. If 3 cubic centimetres of the Oil be shaken with an equal volume of *carbon bisulphide*, and 1 cubic centimetre of *sulphuric acid* be then added, the mixture on being shaken should not become brown (absence of various fixed oils, including cotton-seed oil). Equal volumes of Castor Oil and *petroleum spirit* do not yield a clear mixture if kept at 60° F. (15·5° C.); but they yield a perfectly clear solution if other fixed oils be present." *Br.*

Weaker alcohol, of the sp. gr. 0·8425, takes up about three-fifths of its weight. It has been supposed that adulterations with other fixed oils might thus be detected, as the latter are much less soluble in that fluid; but Pereira has shown that castor oil has the property of rendering a portion of other fixed oils soluble in alcohol: so that the test cannot be relied on. (*P. J. Tr.*, ix. 498.) Such adulterations, however, are seldom practised in this country.* Castor oil is soluble also in ether, and in its weight of glacial acetic acid. Its proximate composition † has been repeatedly investigated. The bulk of it is *ricinolein*,‡ $C_3H_5(C_{18}H_{33}O_3)_3$, which is the *ricinoleic acid* ($C_{18}H_{34}O_3$) glyceride. At the same time it also contains a small quantity of tristearin and of the glyceride of dihydroxystearic acid, together with from 0·30 to 0·37 per cent. of unsaponifiable matter. Ricinoleic acid is a viscid oil, which solidifies below 0° C., does not solidify in contact with the air by absorption of oxygen, and is not homologous with oleic or linoleic acid, neither of which is found in castor oil. On warming with 1 part of starch and 5 parts of nitric acid (sp. gr. 1·25), castor oil thickens, owing to the formation of *ricinelaidin*. From this *ricinelaidic acid* may be obtained in brilliant crystals. Ricinoleic acid is converted by caustic potassa into caprylic alcohol and sebacic acid, with disengagement of hydrogen; and the same products are obtained by the reaction of potassa with the oil itself. (See *Journ. de Pharm.*, Août, 1885, 113.) Its purgative property is supposed by MM. Bussy and Lecanu to belong essentially to the oil, and not to any distinct principle which it may hold in solution. According to M. O. Popp, castor oil differs from all other fixed oils in turning the plane of polarized light to the right. (*A. J. P.*, Aug. 1871, 354; from *Arch. de Pharm.*, 1871.) Various substances containing coloring principles which they yield to castor oil produce beautiful fluorescence in that fluid when heated with it, such as logwood, turmeric, camwood, etc. (Charles Horner, *P. J. Tr.*, Oct. 1874, p. 282.)

Castor oil which is acrid to the taste may sometimes be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through coarse paper. On exposure to the air it is apt to become rancid, and is then unfit for use.

Medical Properties and Uses. Good castor oil is a mild and speedy cathartic, usually operating with little griping or uneasiness, and evacuating the contents of the bowels without much increasing the alvine secretions. Hence it is particularly applicable to *constipation* from collections of indurated fæces, and to cases in which acrid substances have been swallowed or

* *Cohesion figures as a means of testing liquids.* A mode of testing oily or resinous liquids has been proposed by Mr. Charles Tomlinson, which is applicable to this oil, and may succeed when purely chemical methods fail. When one liquid is dropped on the surface of another, there are often curious figures produced, as the drop spreads out on the surface of the liquid upon which it falls, occasioned by the conflict between the cohesion of the drop and the forces which cause its diffusion. These the author calls *cohesion figures*. As a rule, each liquid has its own characteristic figures, which are modified by the admixture of other liquids, and thus the means are afforded of testing not only the identity of any suspected liquid, but also its purity. To one not acquainted with the characteristic cohesion figures, it would be sufficient to try the experiment with a specimen known to be pure, and then to compare with the figure it forms, those formed by the specimen to be tested. The experiment should always be made under precisely similar circumstances. In reference to castor oil, it should be dropped from the end of a glass rod upon the surface of perfectly clear water, in a glass vessel scrupulously clean, as any imperfection in these respects might interpose a physical impediment to the success of the experiment. (*Chem. News.*, Feb. 13, 1864, p. 79. See, also, *A. J. P.*, July, 1864.)

Effect on light. Another test for castor oil is its influence on polarized light. The fixed oils generally have little or no power. Castor oil deviates the plane of polarization to the right, but loses this property if heated to 270° C. (518° F.). (*Journ. de Pharm.*, Nov. 1861, p. 339.)

† When distilled in vacuo it yields at first about one-third of its volume of nearly pure œnanthol, and after this, with great rise of temperature, a crystallizing body belonging to the oleic acid group and having the formula $C_{11}H_{20}O_2$. (*A. J. P.*, 1878, p. 182.)

‡ Buchheim believes the active principle of castor oil to be *ricinoleic acid*; this has been confirmed by the experiments of Prof. Hans Meyer (*Archiv f. Exper. Path.*, xxviii. 1890), who finds that both pure ricinoleic acid and the ricinoleate of glycerin are active purgatives. Ricinelaidic acid, which Buchheim believes to be inactive, Meyer finds when given in fine emulsion to act as powerfully as does castor oil.

acrid secretions have accumulated in the bowels. From its mildness it is also especially adapted to diseases attended with irritation or inflammation of the bowels, as *colic*, *diarrhœa*, *dysentery*, and *enteritis*. It is habitually resorted to in cases of *pregnant* and *puerperal women*, and is decidedly, as a rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults.

The dose for an adult is half a fluidounce (15 C.c.), for an infant from one to three or four fluidrachms (3·75–11·25–15 C.c.) It is difficult of administration, from its peculiarly disagreeable taste and from its clamminess and adhesiveness to the mouth. In a few cases, the disgust which it excites is utterly unconquerable by any effort of resolution. A common method of disguising the drug is to give it floating in mint or cinnamon water; but that which we have found upon the whole the least offensive is to give it floating on the froth of sarsaparilla syrup mixed with carbonic acid water. Some take it in wine, or spirituous liquors, or the froth of porter; but these are often contra-indicated by their stimulant property. An excellent method is to mix it with an equal amount of glycerin and strongly aromatize with a volatile oil. It separates on standing, but can readily be reincorporated by shaking. When the stomach is unusually delicate, the oil may be made into an emulsion with mucilage or the yolk of an egg, loaf-sugar, and an aromatic water. Tragacanth has been recommended as producing a better emulsion than gum arabic. Laudanum may be added in cases of intestinal irritation. Castor oil may also be beneficially used as an enema, in the quantity of two or three fluidounces (60 or 90 C.c.), mixed with some mucilaginous liquid. It has been recommended as a local application to the breasts of nursing women, to promote the secretion of milk.

Though apt to become rancid by itself, it loses much of its susceptibility when mixed with lard; and some druggists are said to use it as a substitute for olive oil in ointments and cerates.

OLEUM ROSÆ. U. S., Br. Oil of Rose.

(Ō'LḘ-ŬM RŌ'ṢÆ.)

"A volatile oil distilled from the fresh flowers of Rosa damascena, Miller (nat. ord. Rosaceæ). It should be kept in well-stoppered vials, in a cool place, protected from light. When dispensed, it should be completely liquefied by warming, if necessary, and well mixed by agitation." *U. S.* "The oil distilled from the fresh flowers of Rosa damascena, Linn." *Br.*

Oleum Rosarum; Attar, Otto of Rose; Essence de Rose, *Fr.;* **Rosenöl,** *G.*

This is commonly called *attar*, *otto*, or *essence of roses*. It is prepared on a large scale in Turkey in Europe, especially in the Balkan Mountains, in Egypt, Persia, Cashmere, India, and other countries of the East; but European and American commerce is at present supplied chiefly from the region constituting the southern slope of the Balkans. Kizanlik is said to be the district in which the oil is most largely produced, 500,000 metticals (about 3000 avoirdupois pounds) being at present the annual amount obtained. The roses are gathered in May, and are distilled with the green leaves of the calyx. They are put, to the amount of 30 or 60 pounds, into a tinned copper boiler of the capacity of about 150 pounds. The heat is applied over an open fire, and a boiling temperature is continued for two hours, when the first part of the distilled fluid is returned to the boiler, and the process is continued to completion. The oil collects on the top of the water in the receiver, where it is removed from time to time as it accumulates. (*P. J. Tr.*, June, 1872, p. 1051.) In the south of France it is prepared in small quantities by distilling the petals of the rose with water. The oil concretes and floats upon the surface of the water when it cools. The precise species of rose from which the oil is extracted is not in all instances certainly known; but it is said to be obtained from *R. damascena* in Northern India, *R. moschata* in Persia, and *R. centifolia* (*provincialis*) in the north of European Turkey. Dr. Hochstell, of the Vienna University, who travelled in the region of the rose-culture, and from whose paper the facts just mentioned were chiefly derived, states that the most important species cultivated in the valley of Kizanlik are *R. damascena*, *R. sempervirens*, and *R. moschata*. It is furnished in very minute proportion, not more than three drachms having been obtained by Colonel Polier, in Hindostan, from 100 pounds of the petals. It is usually imported in small bottles, and is very costly.* Oil of rose is said to be prepared in Macedonia by crushing the petals in mills, expressing the fluid part, filtering it, and then exposing it to the sun in small glass vessels. The oil gradually collects on the surface of the liquid, and is removed. (*Pharm. Centralbl.*, 1847, p. 783.) Landerer states that at Damascus and in other

* For an account by Dr. R. Bauer, of Constantinople, of oil of rose, its production, properties, adulteration, etc., see *P. J. Tr.*, Dec. 1867, 286; also *A. J. P.*, 1881, 367.

parts of Asia Minor the oil is prepared by dry distillation. The buds, being collected before sunrise, are placed in a glass retort, and the distillation is effected by a salt-water bath, care being taken so to regulate the heat as not to scorch the petals. The water of the fresh roses and their oil come over together, and the latter, floating on the top, is readily separated.*

Oil of rose is nearly colorless, or presents some shade of green, yellow, or red, but, according to Polier, the color is no criterion of its value. It is concrete below 80° F., and becomes liquid between 84° and 86° F. Its odor is very powerful and diffusive. At 90° F. its sp. gr. is 0·832. Alcohol dissolves it, though not freely when cold. It is officially described as "a pale yellowish, transparent liquid, having the strong, fragrant odor of rose, and a mild, slightly sweetish taste. Specific gravity, 0·865 to 0·880 at 20° C. (68° F.). It is but slightly soluble in alcohol, and neutral to litmus paper moistened with alcohol. The congealing and melting points of the Oil are subject to some variation, depending upon the amount of stearopten, but, when slowly cooled to a temperature, usually, between 16° and 21° C. (60·8° and 69·8° F.), it becomes a transparent solid, interspersed with numerous slender, shining, iridescent, scale-like crystals. Upon the application of the heat of the hand, the crystals should float in the upper portion of the liquefied Oil. If to 5 drops of the Oil, contained in a test-tube, 5 drops of concentrated sulphuric acid be added, a reddish-brown, thick mixture will be produced, but no white fumes or tarry odor should be developed, and the fragrant odor of the Oil should not be destroyed. If this mixture be then shaken with 5 C.c. of alcohol, the resulting liquid may be turbid, but should be nearly colorless, and should not at once assume a red or reddish-brown color (absence of *oil of ginger-grass* or *Turkish oil of geranium*, from *Andropogon Schœnanthus* Linné (nat. ord. *Gramineæ*), and of oil of *rose geranium*, from *Pelargonium Radula* (Cavanilles) Aiton, *Pelargonium capitatum* (Linné) Aiton, and *Pelargonium odoratissimum* (Linné) Aiton; nat. ord. *Geraniaceæ*)." *U. S.* "A pale yellow crystalline semi-solid, with the strong fragrant odor of rose and a sweet taste. Specific gravity 0·856 to 0·860 at 86° F. (30° C.). The congealing and melting points vary according to the proportion of crystalline matter, but should lie between 67° and 72° F. (19·4° and 22·2° C.)." *Br.* Oil of rose consists of two portions, one liquid, the other concrete at ordinary temperatures. These may be separated by freezing the oil and compressing it between folds of blotting-paper, which absorbs the liquid oil and leaves the concrete stearopten. The liquid portion is oxygenated, while the solid portion, which is odorless when pure, consists of a mixture of several hydrocarbons, one of which melts at from 35·5° to 36·5° C., and is a paraffin of the formula $C_{20}H_{42}$. A sample of oil of rose distilled in Leipsic in 1884 yielded 28 per cent. of this stearopten, an inferior oil distilled in London gave 68 per cent., and a very good oil from the Balkans gave 9·20 per cent. The odor resides exclusively in the liquid oil, the pure stearopten being scentless. The oxygenated portion consists of the two alcohols, $C_{10}H_{18}O$ and $C_{10}H_{20}O$, the former constituting 75 per cent. of the oil. This alcohol is now recognized as identical with the *geraniol* of palma rosa oil, while the compound $C_{10}H_{20}O$ corresponds to that obtained by the reduction of citronellol, and has been named by Dodge, its discoverer, *citronellol*. The rhodinol of Eckart was a mixture of these two alcohols. (*Schimmel's Report*, April, 1898, 40.)

Oil of santal, other volatile oils, fixed oils, spermaceti, etc., are said to be added almost universally as adulterations. The volatile additions may be detected by their not being concrete; the fixed, by the greasy stain they leave on paper when heated. Guibourt has offered certain tests by which he thinks the purity of the oil may be determined. (See *A. J. P.*, xxi. 318.) A. Ganswindt recommends the following tests. Agitate 1 drop of the oil with 45 Gm. of warm water, and sprinkle the solution in a moderately warm room, which will soon be filled with a rose odor, in which foreign odors may be detected without difficulty. An adulteration with a fixed oil produces a permanent grease-stain upon paper, and spermaceti is left behind on the evaporation of a few drops of the oil from a watch-crystal in a water-bath. On mixing a few drops of pure oil of rose with an equal bulk of sulphuric acid, the rose odor is not changed, but oils used for adulteration change their odor, which becomes apparent in the rose odor. Or 5 drops of the oil are mixed in a dry test-tube with 20 drops of pure concentrated sulphuric acid; when the mixture is cool it is agitated with 20 Gm. of absolute alcohol, when a nearly clear solution should be obtained, which, heated to boiling, remains clear yellowish brown on cooling. In the presence of the oils of rose geranium, palma rosa, etc., the alcoholic

* The experiments of Messrs. Schimmel are said to indicate that the oil of rose can be prepared from German-grown flowers with commercial success. It is affirmed that the product is superior to the Turkish oil in fineness and strength of aroma, and also that it differs in having a higher congealing point,—German oil solidifying at 32° C., Turkish oil at 20° C. For an account of its production, see *P. J. Tr.*, Aug. 1886; also *P. J. Tr.*, 1893, 262.

mixture is turbid, and on standing separates a deposit without becoming clear. (*Seifens. Ztg.*, 1881, p. 32; *A. J. P.*, May, 1881.) The oil of one of the sweet-scented Pelargoniums, perhaps the *rose geranium*, is much employed in Turkey for the purpose of adulteration. According to Mr. Hanbury, who appears to have thoroughly investigated the subject, two substances especially are used in Constantinople for adulterating the oil,—one spermaceti, the other a volatile oil produced by certain grasses in the East Indies belonging to the genus *Andropogon*, large quantities of which are exported from Bombay, partly directly to Europe, partly through the Arabian Gulf, whence it reaches Constantinople. The same oil is imported into London under the name of *Turkish essence of geranium*, or *geranium oil*.* Tedermann (*Zeit. Anal. Chem.*, 1895, 5) reached the conclusion, after much experimenting, that there is no reliable chemical or physical test for the adulteration of oil of rose with geranium oil. The sense of smell, according to Conroy, furnishes the best means of determining the quality; he recommends the dissolving of one drop of oil of rose in twenty drops of alcohol, pouring the solution in one fluidounce of warm water, shaking, and comparing the odor with that of a standard sample treated in the same way. (*P. J. Tr.*, 1896, 474; see also *Chem. and Drug.*, 1897, 53.) O. Helm (*Archiv d. Pharm.*, 1885) states that the test with a mixture of five parts of chloroform and twenty parts of alcohol cannot be relied upon, as no separation of crystalline scales took place in four different rose oils which were doubtless genuine. But Prof. Flückiger (*Archiv*, 185), on the other hand, states that in an experience of many years it has never failed. For other tests for oil of rose, see *N. R.*, 1883; *Drug. Circ.*, 1886. According to Bauer, the best tests of the purity of the oil are found in its congealing, in five minutes, at a temperature of 12·5° C. (54·5° F.), and its crystallizing, as a solid mass, in light, shiny plates, present everywhere throughout the liquid. These crystals are truncated semi-sided prisms, the angles of which are unequal, and which must be classed in the rhombic system. This stearopten, melted and allowed to cool, crystallizes in a manner so complete that the microscope can readily reveal the presence of foreign substances, such as spermaceti, fatty bodies, wax, and other analogous amorphous substances.

Oil of rose may be added, as a grateful perfume, to various spirituous preparations for internal use, and to cerates and ointments.

OLEUM ROSMARINI. U. S., Br. Oil of Rosemary.

(Ō'LĒ-ŬM RŎS-MA-RĪ'NĪ.)

"A volatile oil distilled from the leaves of Rosmarinus officinalis, Linné (nat. ord. Labiatæ)." *U. S.* "The oil distilled from the flowering tops of Rosmarinus officinalis, Linn." *Br.*

Oleum Anthos; Essence de Romarin, *Fr.*; Rosmarinöl, *G.*

The fresh leaves of rosemary yield, according to Baumé, 0·26 per cent. of volatile oil; but the product is rated much higher by others. According to Brande, a pound of the fresh herb yields about a drachm of the oil, which is about 1 per cent.; and Zeller gives very nearly the same product for the dried herb. This oil is colorless, with an odor similar to that of the plant, though less agreeable. Its sp. gr. is said to be 0·911, but reduced to 0·8886 by rectification (0·895 to 0·915, *U. S.*). Buignet gives the sp. gr. of the rectified oil at 0·896, and states that it is moderately dextrogyrate. Its reaction is neutral. It is soluble in all proportions in alcohol of 0·830, but requires for solution at 64° F. forty parts of alcohol of 0·887. (*Berzelius.*) "Soluble in an equal volume of alcohol, the solution being neutral, or very slightly acid, to litmus paper; also soluble in an equal volume of glacial acetic acid." *U. S.* "Specific gravity 0·900 to 0·915. It should dissolve in twice its volume of *alcohol* (90 per cent.), and should not rotate the plane of a polarized ray of light more than 10° to the right in a tube 100 millimetres long (absence of oil of turpentine)." *Br.* Kane gives its sp. gr. at 0·897, its boiling point at 365° F. Kept in bottles imperfectly stopped, it deposits a *stearopten*, sometimes amounting, according to Proust, to one-tenth of the oil. Both Gladstone and Flückiger find that most of the oil consists of a hydrocarbon of the composition $C_{10}H_{16}$, boiling at 165° C. (329° F.), and Schimmel & Co. (*Report*, Oct. 1889) identified this hydrocarbon as *pinene;* but there is a smaller fraction boiling at from 200° to 210° C. (392°–410° F.), which at low temperatures deposits a camphor, $C_{10}H_{18}O$, identified as borneol. Weber examined oil of rosemary in Wallach's laboratory (*Ann. Chem. Pharm.*, 238, 89–108), and found that the fraction boiling between 176° and 182° C. contains *cineol*, $C_{10}H_{18}O$. The oil is therefore recognized at

* *Oil of Rhodium.* This is said to be the oil from the wood of *Convolvulus scoparius* or *Genista canariensis.* It is used to adulterate oil of rose. An oil of rhodium is sold to rat-catchers as a lure for rats, which is made by mixing one part of oil of rose with twenty parts of oil of copaiba.

present as containing dextrogyrate pinene, cineol, borneol, and camphor. According to Flückiger (*A. J. P.*, 1885, 132), from 20,000 to 25,000 kilogrammes of oil of rosemary are produced in Grasse every year. It is said to be sometimes adulterated with oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol: the oil of rosemary is dissolved, and that of turpentine left. This oil is stimulant, but is employed chiefly as an ingredient of rubefacient liniments. The dose is from three to six drops (0·18–0·36 C.c.). For a case of fatal poisoning, see *A. J. P.*, xxiii. 286.

OLEUM SABINÆ. U. S. Oil of Savine.

(Ō′LḘ-ŬM SA-BĪ′NÆ.)

"A volatile oil distilled from Savine." *U. S.*

Essence de Sabine, *Fr.;* Sadebaumöl, *G.*

According to the more recent authorities, the proportion of volatile oil obtained from savine varies as much as from 1 to 2·5 per cent. The oil is nearly colorless or yellow, limpid, strongly odorous, and of a bitterish, extremely acrid taste. "Specific gravity, 0·910 to 0·940 at 15° C. (59° F.). Soluble in an equal volume of alcohol (distinction from *oil of juniper* and *oil of turpentine*), the solution being neutral to litmus paper; also soluble in an equal volume of glacial acetic acid." *U. S.* According to Schimmel & Co. (*Report*, April, 1897), its specific gravity is from 0·91 to 0·925, optical rotation +45° to +60°, and it contains *pinene*, $C_{10}H_{16}$, and *cadinene*, $C_{15}H_{24}$. With iodine it becomes heated, detonates, and gives off yellow and violet-red vapors. (Flaschoff.) The oil of savine is a powerful local irritant, producing, when persistently applied to the skin or the mucous membrane, violent inflammation. It has been much used for the purpose of producing criminal abortion, and in a number of such cases has caused death, the symptoms being violent abdominal pain, bloody vomiting and purging, diminution or suppression of urine, disordered respiration, unconsciousness, convulsions, and fatal collapse. It is a powerful stimulant to the uterine system, and has been given with alleged success in *atonic amenorrhœa* and *menorrhagia*. The dose is from two to five drops (0·12–0·3 C.c.). Externally, Dr. Pincus has used it successfully, in the proportion of from five to thirty drops in an ounce of spirit, for the cure of *alopecia pityroides*. He has it rubbed on the head and also applied by means of compresses.

OLEUM SANTALI. U. S., Br. Oil of Santal.

(Ō′LḘ-ŬM SĂN′TA-LĪ.)

"A volatile oil distilled from the wood of Santalum album, Linné (nat. ord. Santalaceæ)." *U. S.* "The oil distilled from the wood of Santalum album, Linn." *Br.*

Oleum Santali Flavi; Oil of Sandal Wood; Essence de Santal, *Fr.;* Santelöl, *G.*

Under the name of sandal wood various drugs of diverse origin and character find their way into commerce. Of these, the wood of the *Pterocarpus santalinus* is described in this book under its official name of *Santalum rubrum*, or *Red Saunders*. *Sandal wood bark*, which is believed by H. Stieren to be obtained from some species of Myroxylon or Myrospermum, is described as occurring in irregular, more or less smooth or unevenly corrugated pieces, of a light, whitish-cinnamon color, with dark, hard epidermis, and of an agreeable, custard-like smell, and an aromatic, slightly acrid, balsamic, bitterish taste. From it Dr. Stieren obtained over fifteen per cent. of a clear substance resembling Peruvian balsam. This bark is used for burning in churches as a substitute for frankincense, and bears no relation to sandal wood proper. (*P. J. Tr.*, xv. 680.) A sandal wood is yielded by the *Fusanus spicatus* and *F. acuminatus* of Australia, whence it is shipped in large quantities to China. An oil distilled from this wood, now coming into the European market, is said to be less odorous than the official product. Other varieties of sandal wood are collected in the Sandwich Islands from *Santalum freycinetianum*, Gaud., and *S. pyrularium*, A. Gray; in the Feejee Islands from *S. yasi*, Seem.; in New Caledonia from *S. austrocaledonicum*, Vieillb.; and in Queensland from *Eremophila mitchelli*. For an account of the sandal wood oil industry of Western Australia, see *Chem. and Drug.*, 1898, 708. A considerable quantity of oil enters commerce under the name of *West Indian sandal wood oil*, the wood which produces it being known as *Venezuela sandal wood*. This wood is entirely distinct in its botanical relation and in its microscopic character from the true sandal wood. It appears to be obtained from species belonging to the Rutaceæ. For elaborate microscopic descriptions of the sandal woods, method of obtaining the oil, etc., see various papers in the *P. J. Tr.*, vol. xvi.; also *Bull. Pharm.*, 1895, 55.

The *Santalum album*, which yields the official oil, is a small tree twenty to thirty feet high, a native of the mountainous portions of India and of various islands of the Eastern Archipelago, but cultivated in India for the sake of its oil.

Oil of santal is distilled in Germany, England, and India; the English oil being the highest priced and the most esteemed, on account of its general purity. According to the Indian Pharmacopœia the yield of oil is about 2·5 per cent. Oil of santal is habitually adulterated, castor and other fixed oils being largely added, and on the continent of Europe the *volatile oil of cedar*, which is obtained by distilling the chips left in the making of lead-pencils. Chapoteaut (*Bulletin de la Soc. Chim.*, 37, p. 353) found two constituents, one of which he calls *santalol*, $C_{15}H_{26}O$, boiling at 310° C., and the other *santalal*, $C_{15}H_{24}O$, boiling at 300° C. Both of these are decomposed by distilling over phosphoric anhydride, the one yielding $C_{15}H_{24}$, boiling point 260° C., and the other $C_{15}H_{22}$, boiling point 245° C. A specimen of oil of santal from South Australia, examined by Schimmel & Co. (*Report*, Oct. 1891), afforded a white crystalline principle, melting at 104°–105° C., which crystallized out in the oil. The U. S. Pharmacopœia describes the oil of santal as "a pale yellowish or yellow, somewhat thickish liquid, having a peculiar, strongly aromatic odor, and a pungent, spicy taste. Specific gravity, 0·970 to 0·978 at 15° C. (59° F.). It deviates polarized light to the left (distinction from *Australian* (spec. grav. 0·953) and *West Indian* (spec. grav. 0·965) *Sandal Wood Oil*, which deviate polarized light to the right). Readily soluble in alcohol, the solution being slightly acid to litmus paper. If to 1 C.c. of the Oil, at 20° C. (68° F.), there be added 10 C.c. of a mixture of 3 volumes of alcohol and 1 volume of water, a perfectly clear solution should be obtained (test for *cedarwood oil*, *castor oil*, and *other fatty oils*, etc.)." *U. S.* "Somewhat viscid in consistence, pale yellow in color, having a strongly aromatic odor and a pungent and spicy taste. Specific gravity 0·975 to 0·980. It forms a clear solution with six times its volume of *alcohol* (70 per cent.) (absence of cedar wood oil). It rotates the plane of a ray of polarized light to the left, through an angle of not less than 16° and not more than 20°, in a tube 100 millimetres long (absence of other varieties of sandal wood oil)." *Br.*

The Indian Pharmacopœia gives the sp. gr. of the oil at 0·98, the British at 0·96, while in a number of specimens examined by E. M. Holmes (*P. J. Tr.*, xvi. 821) the sp. gr. varied from 0·96 to 0·99. The sp. gr. of the oil of cedar wood, according to Mr. Ince, is 0·948. A large percentage of it may be added to the oil of santal without affecting its density sufficiently to be detected. Holmes states that the presence of more than 10 per cent. of the cedar oil can be recognized through the different solubilities of the oils in alcohol. (See *P. J. Tr.*, xvi. 820.) R. A. Cripps, after a thorough examination of the oils in the London market (see *P. J. Tr.*, 1892, 461), gives this test: "Two drops of the oil added to six drops of nitric acid, sp. gr. 1·5, on a white tile, should give a yellow to bright reddish-brown coloration, without any green, indigo, or violet tint at the edges during five minutes. For complete saponification in alcoholic solution, it requires not more than 1 per cent. of potassium hydrate." (See also *A. J. P.*, 1893, 20; *Schimmel's Report*, Oct. 1893; *P. J. Tr.*, 1895, 118; *West. Drug.*, 1897, 262.) West India oil can be distinguished from the genuine oil by its deviating the plane of polarization to the *right* instead of to the *left*. (*Pharmacographia.*) In two specimens of oil of santal, sp. gr. 0·9649 and 0·9573, F. H. Alcock found strong fluorescence. (*P. J. Tr.*, 1886, 923.)

Medical Properties. The oil of santal is used chiefly as a perfume, but it is also a very valuable remedy in the treatment of *chronic* and *subacute inflammations* of the *mucous membranes*, especially in *bronchitis* and in *gonorrhœa* when the first period of severe acute inflammation has passed. It is in concentrated form a local irritant, and probably is capable of causing more or less systemic excitement, although the effects of large doses of it upon the general organism are not well known. It may be given in doses of from fifteen to twenty minims (0·9 to 1·25 C.c.), in emulsion, or preferably in capsule, three or four times a day. It was first recommended by Dr. Thos. B. Henderson in gonorrhœa, who is, however, stated to have used the oil of *S. myrtifolium.*

OLEUM SASSAFRAS. U. S. Oil of Sassafras.

(Ō'LḘ-ŬM SĂS'SA-FRĂS.)

"A volatile oil distilled from Sassafras." *U. S.*

Essence de Sassafras, *Fr.*; Sassafrasöl, *G.*

The proportion of oil yielded by the root of sassafras is variously stated at from less than 1 to somewhat more than 2 per cent. The bark of the root, directed by the U. S. Pharmacopœia, would afford a larger amount. Very large quantities of the oil are distilled in Mary-

land and sent to Baltimore for sale. The usual yield is said by Mr. Sharp to be one pound from three bushels of the root. From fifteen to twenty thousand pounds were sent annually, before the war, to the Baltimore market. (A. P. Sharp, *A. J. P.*, Jan. 1863, p. 53.) At Richmond, Va., in 1871, it was being manufactured at the rate of forty gallons of pure oil per week. The root, chopped fine by machinery, has steam forced through it in a closed tub, and the oil is then distilled in the ordinary way. 800 pounds of unrectified oil are said to be obtained from 40,000 pounds of the root. (*Med. and Surg. Reporter*, Aug. 26, 1871.) The oil is of a yellow color or colorless, becoming reddish by age. It has the fragrant odor of sassafras, with a warm, pungent, aromatic taste, and a neutral reaction. It is among the heaviest of the volatile oils, having the sp. gr. of 1·094, or 1·087 on the authority of Buignet, who states also that it is very slightly dextrogyrate. It is officially described as "a yellowish or reddish-yellow liquid, having the characteristic odor of sassafras without the odor of camphor, and a warm, aromatic taste. It becomes darker and thicker by age and exposure to the air. Specific gravity, 1·070 to 1·090 at 15° C. (59° F.). Soluble, in all proportions, in alcohol, the solution being neutral to litmus paper; also soluble, in all proportions, in glacial acetic acid, and in carbon disulphide. If to 5 drops of the Oil 5 drops of nitric acid be added, a violent reaction will take place, producing at first a red color, and finally converting the Oil into a red resin. If to a few drops of the Oil a drop of sulphuric acid be added, a deep-red color will be produced at first, which soon becomes blackish." *U. S.* The most complete investigation of sassafras oil is that made by Drs. Power and Kleber in 1896. (*Schimmel's Report*, April, 1896.) They find it to have the following composition: safrol, $C_{10}H_{10}O_2$, about 80 per cent.; pinene and phellandrene, $C_{10}H_{16}$, about 10 per cent.; dextrogyrate camphor, $C_{10}H_{16}O$, about 6·8 per cent.; eugenol, $C_{10}H_{12}O_2$, about 0·5 per cent.; a high-boiling portion consisting of cadinene and residue, 3 per cent. They say that the hydrocarbon constituent of sassafras oil, to which Grimaux and Ruotte gave the name of safrene, is, as just stated, a mixture of pinene and phellandrene. Safrol crystallizes well in hard four- or six-sided prisms, with the odor of sassafras. It liquefies at 85° C. (47° F.), boils at 232° C. (449·6° F.), has a sp. gr. of 1·108, and is destitute of rotatory power. Variation in the sp. gr. of oil of sassafras may often arise through the congelation and separation of safrol, or through stratification. (Lawall and Pursel, *A. J. P.*, 1898, 340.) Prof. Flückiger ascertained that safrol was one of those remarkable bodies which are capable of existing either in a solid or in a fluid condition long after they have passed their freezing or their melting point. Chemically, it has been found to be the *methylene ether of allyl-dioxybenzene*. Safrol appears to be widely distributed in the vegetable kingdom, probably existing in the bark of the *Mespilodaphne sassafras*, also in the *Puchury* or *Sassafras nuts*, both of Brazil, as well as in the barks of *Atherosperma moschatum* and of *Beilschmiedia obtusifolia* of Australia, and in the bark of *Doryphora sassafras* of New Caledonia. It is now commercially extracted from oil of camphor, and it probably could be obtained from the oil of various species of the genus *Cinnamomum*. (See *P. J. Tr.*, June, 1887.)

Oil of sassafras is chiefly used for flavoring purposes, but has physiological properties similar to those of the oil of cloves and other allied volatile oils, and may be used for similar purposes. A teaspoonful of it produced in a young man vomiting, collapse, somewhat dilated pupils, and pronounced stupor. (*Cincinnati Lancet-Clinic*, Dec. 1888.) According to the experiments of A. Heffter (*Atti Dell' xi. Congres. Med. Internaz.*, iii., 1894), safrol is slowly absorbed from the alimentary canal, and escapes through the lungs unaltered and through the kidneys oxidized into *piperonalic acid*. When taken in sufficient dose, it quickly kills by a centric paralysis of respiration, preceded by great depression of the circulation; and when taken in smaller yet toxic amount, it causes death by wide-spread fatty degeneration of the heart, liver, kidneys, etc. Its isomer, *isosafrol*, is in warm-blooded animals much less active as a poison than is safrol, and is chiefly eliminated as *piperonalic acid*.

OLEUM SESAMI. U. S. Oil of Sesamum. [Sesame Oil. Teel Oil. Benne Oil.]

(Ō'LĒ-ŬM SĔS'Ą-MĪ.)

"A fixed oil expressed from the seed of Sesamum indicum, Linné (nat. ord. Pedaliaceæ)." *U. S.*

Benne Oil; Huile de Sésame, Sésame, *Fr.;* Sesam, Sesamöl, *G.;* Sesamo, *It.;* Ajonjoli, *Sp.*

Sesamum indicum, L. *Gen. Pl.* ii. 1058; Willd. *Sp. Plant.* iii. 359; Curtis, *Bot. Mag.* vol. xli. t. 1688; *B. & T.* 198. "Leaves ovate-lanceolate, the inferior three-lobed, the superior undivided. Stem erect."

The benne plant of our Southern States is annual, with a branching stem four or five feet

high, and bearing opposite, petiolate leaves, varying considerably in their shape. Those on the upper part of the plant are ovate-lanceolate, irregularly serrate, and pointed, those near the base three-lobed and sometimes ternate; and lobed leaves are not uncommon at all distances from the ground. The flowers are reddish white, and stand solitarily upon short peduncles in the axils of the leaves. The fruit is an oblong capsule, with small, oval, yellowish seeds.

There are some ten or twelve species referred to the genus Sesamum, the majority of which are natives of Africa. In India one or two species occur wild; one of these, Sesamum Indicum (syn. *S. orientale*), has been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the negroes to the United States, where, as well as in the West Indies, it is now cultivated to a considerable extent. The plant above described will grow vigorously in the gardens as far north as Philadelphia, though it does not usually ripen its seeds in this vicinity. The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which was introduced into the Pharmacopœia at the revision of 1880. M. Berjot obtained 53 per cent. of the oil by means of carbon disulphide.

1. *Benne Leaves.* These abound in a gummy matter, which they readily impart to water, forming a rich, bland mucilage, much used in the Southern States as a drink in various complaints to which demulcents are applicable, as in *cholera infantum*, *diarrhœa*, *dysentery*, *catarrh*, *acute cystitis*, *strangury*, etc. The remedy has attracted attention also in the North, and has been employed with favorable results in Philadelphia. One or two fresh leaves of full size, stirred about in half a pint of cool water, will soon render it sufficiently viscid. With dried leaves hot water is used. The leaves also serve for the preparation of emollient cataplasms.

2. *Benne Oil.* This is inodorous, of a bland, sweetish taste and a neutral reaction, and will keep long without becoming rancid. Flückiger finds that 76 per cent. of the oil consists of *olein*, and that the solid portions yield on saponification *palmitic*, *stearic*, and *myristic acids*. The oil also contains a small quantity of what is probably a resinoid substance, which may be removed by glacial acetic acid or alcohol. It bears some resemblance to olive oil in its properties, and may be used for similar purposes. It is not a drying oil. Villavecchia and Fabris (*Zeit. für Angew. Chem.*, 1893, 505) have recently investigated sesame oil, and find, in addition to the main constituents before mentioned, a higher alcohol of the formula $C_{25}H_{44}O$, fusing at 137° C., a finely crystallizing substance of the formula $C_{11}H_{12}O_3$,* fusing at 123° C., which substance they name *sesamin*, and a thick uncrystallizable oil, non-nitrogenous, which is the cause of the cherry-red coloration which sesame oil shows with hydrochloric acid and sugar. "Specific gravity, 0·919 to 0·923 at 15° C. (59° F.). When cooled to —3° C. (26·6° F.) it becomes thick, and at —5° C. (23° F.) it congeals to a yellowish-white mass. Concentrated sulphuric acid converts it into a brownish-red jelly. If 5 C.c. of the Oil be shaken with an equal volume of concentrated hydrochloric acid, the latter will usually assume a bright emerald-green color, especially if the Oil has been exposed for some time to the action of air and light; and, on the subsequent addition of about 0·5 Gm. of sugar, and again shaking the mixture, a blue color, changing to violet, and finally to deep crimson, will be produced." *U. S.* Soltzien recommends stannous chloride solution for testing benne oil. (*Proc. A. P. A.*, 1897, 195.) According to Schaedler, if one C.c. of pure benne oil is shaken with one C.c. of pure hydrochloric acid, sp. gr. 1·125, and one gramme of cane sugar, a rose-red color is developed in fifteen minutes, changing to violet in twenty-five minutes, and increasing in intensity until, after five hours, the acid has assumed a violet color corresponding in intensity to that of a solution of iodine in carbon disulphide or in chloroform. In the case of all other fixed oils, this color reaction does not begin until after three-quarters of an hour. Olive and almond oils containing as little as one-fourth per cent. of benne oil exhibit the reaction in from twenty to twenty-five minutes. The failure of some experimenters to find the reactions available rests upon the fact that they searched for the color in the oil, and not, as they should have done, in the acid. (*Arch. d. Pharm.*, 1887, p. 185.) Benne oil was known to the ancient Persians and Egyptians, and is esteemed by the modern Arabs and other people of the East both as food and as an external application to promote softness of the skin. It is laxative in large doses.

* Tocher (*Pharm. Journ. Trans.*, 1893, 700), after analyzing *sesamin* and determining its molecular weight by Raoult's method in benzene and glacial acetic acid, maintains that its formula should be $C_{18}H_{18}O_5$. Tocher, as quoted by Lewkowitsch (*Chem. Anal. of Oils, Fats, and Waxes*, 2d ed., 389), also believes that the higher alcohol mentioned is cholesterol.

OLEUM SINAPIS VOLATILE. U. S., Br. Volatile Oil of Mustard.

(Ō'LḘ-ŬM SḬ-NĀ'PĬS VǪ-LĂT'Ḭ-LĒ.)

"A volatile oil obtained from Black Mustard by maceration with water and subsequent distillation." *U. S.* "Distilled from Black Mustard Seeds after maceration with water." *Br.*

Oleum Sinapis, *Br.* 1885, *P. G.;* Oleum Sinapis Ætherеum; Essence de Moutarde, *Fr.;* Aetherisches Senföl, *G.*

The *volatile oil of mustard* is usually obtained from seeds which have been deprived of their fixed oil by pressure. It is a colorless or pale-yellow liquid, rather heavier than water, of an exceedingly pungent odor, and an acrid burning taste; with alkaline solutions it yields sulphocyanates. "Specific gravity, 1·018 to 1·029 at 15° C. (59° F.). Boiling point, 148° to 150° C. (298·4° to 302° F.). Freely soluble in alcohol, ether, or carbon disulphide, the solutions being neutral to litmus paper. If to 3 Gm. of the Oil 6 Gm. of sulphuric acid be gradually added, the liquid being kept cool, the mixture, upon subsequent agitation, will evolve sulphur dioxide, but will remain of a light yellow color, and at first perfectly clear, becoming afterwards thick and occasionally crystalline, while the pungent odor of the Oil will disappear. If a portion of the Oil be heated in a flask connected with a well-cooled condenser, it should distil completely between 148° and 150° C. (298·4° and 302° F.), and both the first and the last portion of the distillate should have the same specific gravity as the original Oil (absence of *alcohol*, *chloroform*, *carbon disulphide*, *petroleum*, or *fatty oils*). If a small portion of the Oil be diluted with 5 times its volume of alcohol, and a drop of ferric chloride test-solution be added, no blue or violet color should be produced (absence of *phenols*). If a mixture of 3 Gm. of the Oil and 3 Gm. of alcohol be shaken, in a small flask, with 6 Gm. of ammonia water, it will become clear after standing for some hours, or rapidly when warmed to 50° C. (122° F.), and usually deposit, without becoming colored, crystals of thiosinamine (allyl-thio-urea, $CS.N_2H_3(C_3H_5)$). To determine the proportion of thiosinamine obtainable from the Oil, decant the mother-water from the crystals, and evaporate it gradually in a tared capsule, on a water-bath, adding fresh portions only after the ammoniacal odor of each preceding portion has disappeared. Then add the crystals from the flask to those in the capsule, rinsing them out of the flask with a little alcohol, and heat the capsule on a water-bath until its weight remains constant. The amount of thiosinamine thus obtained from 3 Gm. of the Oil should be not less than 3·25 Gm., nor more than 3·5 Gm. After cooling, thiosinamine forms a brownish, crystalline mass, fusing at 70° C. (158° F.), and having a leek-like, but no pungent, odor. The mass should be soluble in 2 parts of warm water, forming a solution which should not redden blue litmus paper, and which possesses a somewhat bitter, not persistent taste." *U. S.* "Specific gravity 1·018 to 1·030. It distils between 297° F. (147·2° C.) and 306° F. (152·2° C.), and the first and last portions of the distillate should have the same specific gravity as the original Oil (absence of ethylic alcohol and petroleum)." *Br.* Dr. Will considers it to be *allyl* isosulphocyanate (C_3H_5CNS), the compound radical being the same as that of oil of garlic, which is considered a sulphide of allyl. (*Chem. Gaz.*, Nos. 62 and 64.) It is the principle upon which black mustard seeds depend for their activity. Volatile oil of mustard was first produced artificially by MM. Berthelot and S. de Luca, by treating allyl iodide (C_3H_5I) with an alcoholic solution of potassium sulphocyanate. It is now extensively manufactured artificially by this method. What first forms is allyl sulphocyanate, which is not identical with, but only an isomer of, mustard oil (allyl isosulphocyanate.) But if the sulphocyanate be heated to its boiling point (161° C.) the thermometer sinks rapidly to 150° C., because of the change into the isosulphocyanate, or mustard oil. This change also takes place spontaneously at summer temperature. A small quantity of carbon disulphide seems always to be produced at the same time.* Allyl iodide is procured by treating glycerin with phosphorus iodide, and differs from volatile oil of garlic (allyl sulphide) only in containing iodine instead of sulphur. (*Journ. de Pharm.*, Août, 1855, p. 124.) According to Zeller, the seeds yield from 0·33 to 0·63 per cent. of the oil. Will and Koerner in 1863 explained the occurrence of this allyl isosulphocyanate in mustard oil. It does not occur ready formed in the seeds, but is produced by the decomposition of a compound, *sinigrin* (*potassium myronate*), occurring there. This sinigrin, $C_{10}H_{18}KNS_2O_{10}$, is decomposed under the influence of *myrosin*, an albuminous ferment which is present, and yields as products of decomposition C_3H_5CNS (allyl isosulphocyanate), $HKSO_4$ (acid potassium sul-

* *Allyl Hydrobromate.* *Allyl hydrobromate* was first prepared by Wurtz in 1857 (*Ann. de Chimie*, li. 91) by the reaction of allyl iodide on one and a half times its weight of bromine. It is a colorless liquid, soluble in ether, boiling at 170° C., and having a specific gravity of 2·436. Dr. De Fleury (*Arch. de Pharm.*, Aug. 1886) affirms that in doses of five drops, two to four times a day, in capsules, it is a valuable remedy in *hysteria*, *asthma*, and *convulsions*.

phate), and $C_6H_{12}O_6$ (glucose). "The aqueous solution of myrosin coagulates at 60° C. (140° F.), and then becomes inactive; hence mustard seed which has been heated to 100° C. (212° F.), or has been roasted, yields no volatile oil, nor does it yield any if powdered and introduced at once into boiling water." (*Pharmacographia*, p. 67.) As it is often adulterated with other oils, a test has been proposed consisting of concentrated sulphuric acid, 50 drops of which are to be mixed with 5 drops of the suspected oil in a small glass tube. If the oil be pure, little change of color will be produced; but if any adulterating oil be present, a red or brown color will soon appear. Rectified oil of petroleum is the only exception, as the color of this is not affected by the acid; but it would be recognized by its insolubility in sulphuric acid. (See *A. J. P.*, July, 1865, p. 285.) Ammonia converts the mustard oil into *thiosinamin*, according to the reaction $SCN.C_3H_5 + NH_3 = C_4H_8N_2S$, which separates in colorless rhombic crystals, melting at 70° C., and soluble in water, alcohol, and ether. The reaction is stated by Flückiger (*Pharm. Chem.*, 2d ed., 1888, p. 20) to be quantitative. Adulteration with alcohol is readily detected by its much lower boiling point, which also enables it to be separated by distillation. It has been adulterated with considerable quantities of carbon disulphide, which may be detected by distillation at a temperature not exceeding 80° C. and mixing the distillate with sulphuric acid, when the carbon disulphide rises to the surface. Oil of mustard naturally contains about 0·56 per cent. of carbon disulphide. (*A. J. P.*, 1881, p. 572.) The volatile oil of mustard has been employed as a substitute for the mustard plaster. For this purpose one part may be mixed with sixty parts of alcohol, and the mixture applied sprinkled not too thickly on piline. It acts speedily and efficiently.

White mustard seeds yield different products. When deprived of fatty oil they yield to boiling alcohol colorless crystals of *sinalbin*, an indifferent substance readily soluble in cold water, but sparingly so in cold alcohol. According to Will, it breaks up under the action of myrosin into *acrinyl sulphocyanate*, $C_7H_7O.CNS$, *sinapine sulphate*, $C_{16}H_{25}NSO_9$, and *glucose*, $C_6H_{12}O_6$. This acrinyl sulphocyanate is a nearly colorless, non-volatile oil, and the rubefacient and vesicating principle of white mustard. *Sinapine* has not yet been isolated, but it is an unstable alkaloid.

A practical application of the principles developed in the foregoing paragraphs has been suggested by M. Lebaigue, who proposes applying to one sheet of paper a concentrated solution of *potassium myronate*, and to a second a concentrated solution of *myrosin*, and drying them. When used, the leaves are to be moistened and applied to the surface, one over the other. Volatile oil of mustard is formed by the reaction of the two principles, and a sinapism is obtained. (*Journ. de Pharm.*, Août, 1868, p. 118.) From the foregoing account of the chemical relations of mustard, it is obvious that admixture with alcohol or the acids, or the application of a boiling heat, can only have the effect of impairing its medical virtues, and that the best vehicle, whether for external or internal use, is water at common temperatures.

OLEUM TEREBINTHINÆ. U. S., Br. Oil of Turpentine.

(Ō'LḘ-ŬM TĔR-Ḛ-BĬN'THḭ-NÆ.)

"A volatile oil distilled from Turpentine." *U. S.* "The oil distilled, usually by the aid of steam, from the oleo-resin (turpentine) obtained from Pinus sylvestris, Linn., and other species of Pinus; rectified if necessary." *Br.*

Essence de Térébenthine; Huile volatile de Térébenthine, *Fr.;* Terpentinöl, *G.;* Olio della Trementina, *It.;* Aceite de Trementina, *Sp.*

This oil is commonly called *spirits* (or *spirit*) *of turpentine*. It is prepared by distillation from our common turpentine, though equally afforded by other varieties. It may be distilled either with or without water; but in the latter case a much higher temperature is required, and the product is liable to be empyreumatic. To obtain it quite pure it should be redistilled from a solution of caustic potassa. The turpentine of *Pinus palustris* is said to yield about 17 per cent. of oil, while that from *Pinus maritima* affords 25 per cent., and that from *Pinus sylvestris* 32 per cent. Large quantities are distilled in North Carolina. The exportations from the United States for the year ending June 30, 1896, amounted to 16,619,726 gallons, and for the year ending June 30, 1897, 16,609,056 gallons.

Pure oil of turpentine is perfectly limpid and colorless, of a strong, penetrating, peculiar odor, a hot, pungent, bitterish taste, and a neutral or faintly acid reaction. It is much lighter than water, having the sp. gr. 0·855 to 0·876, *U. S.;* is highly volatile and inflammable; boils at a temperature somewhat higher than 148·8° C. (300° F.); is very slightly soluble in water, less soluble in alcohol than most other volatile oils, and readily soluble in ether. Boiling alco-

hol dissolves it with facility, but deposits most of the oil upon cooling. 100 parts of alcohol sp. gr. 0·840 dissolve 13·5 parts of the oil at 22·2° C. (72° F.). "It boils at 155° to 170° C. (311° to 338° F.). Soluble in 3 times its volume of alcohol, the solution being neutral or slightly acid to litmus paper; also soluble in an equal volume of glacial acetic acid. Bromine or powdered iodine acts violently upon it. When brought in contact with a mixture of nitric and sulphuric acids, it takes fire. If a little of the Oil be evaporated in a small capsule on a water-bath, it should leave not more than a very slight residue (absence of *petroleum*, *paraffin oils*, or *resin*)." *U. S.* "Limpid, colorless, with a strong peculiar odor, which varies in the different kinds of Oil, and a pungent and somewhat bitter taste. It is soluble in its own volume of *glacial acetic acid*. It commences to boil at about 320° F. (160° C.), and almost entirely distils below 356° F. (180° C.), little or no residue remaining." *Br.* As found in commerce, it always contains oxygen; but when perfectly pure it consists exclusively of carbon and hydrogen, and is composed of one or more *terpenes*. (See p. 905.) The English or American oil (prepared from *Pinus australis*) is composed of *dextro-pinene*, while the French oil (prepared from *Pinus maritima*) is composed of *lævo-pinene*. On the other hand, the Russian turpentine contains, in addition to *pinene*, *dipentene* (or *cinene*) and *sylvestrene*, and the Swedish turpentine contains *pinene* and *sylvestrene*. Both the American and the French oil of turpentine boil at about 156° C. (312·8° F.). On heating oil of turpentine to about 300° C. (572° F.) in a sealed tube for several hours it is converted into a polymer called *iso-terebenthene*, $C_{20}H_{32}$, which is so oxidizable that it is converted into a viscid mass on exposure to the air for a few hours. It has, moreover, a marked odor, resembling oil of lemon, and boils at 176° to 177° C. (348·8° to 350·6° F.). On treatment with a small portion of sulphuric acid, oil of turpentine yields an optically inactive liquid, which boils at 160° C. (320° F.). This is a mixture resolvable by repeated fractional distillation into *terebene*, $C_{10}H_{16}$, boiling at 150° C. (302° F.); *cymene*, $C_{10}H_{14}$, boiling at 175° C. (347° F.); a small quantity of a camphor-like body, boiling at 200° C. (392° F.); *colophene*, $C_{20}H_{32}$, boiling at 318° C. (604·4° F.), and a mixture of semi-solid products of higher boiling point. Oil of turpentine absorbs hydrochloric acid gas, forming with it two compounds, one a red dense liquid, the other a white crystalline substance resembling camphor, and hence called *artificial camphor*. Both are *mono-hydrochlorides*, $C_{10}H_{16}.HCl$, but the latter is much more stable, and can be purified by crystallization from alcohol or ether. When turpentine oil is left in contact with concentrated hydrochloric acid a *dihydrochloride* is formed, $C_{10}H_{16}.2HCl$. This forms rhombic plates, insoluble in water, and decomposed by boiling with alcoholic potash, with formation of *terpinol* $(C_{10}H_{16})_2.H_2O$. (Allen, *Com. Org. Analysis*, vol. ii. p. 51.) Nitric acid converts oil of turpentine into resin, and by long boiling into *terebic acid*, $C_7H_{10}O_4$. Mixed with water and chlorinated lime, and then distilled, the oil yields a liquid which M. Chautard found to be identical with chloroform. (*Ibid.*, 3e sér., xxi. 88.) Turpentine oil and other terpenes unite with water to form crystals of *terpinhydrate*, $C_{10}H_{18}(OH)_2 + H_2O$, which sublimes often from turpentine oil which has long stood in contact with water and has then been heated to water-bath temperature. These crystals are sometimes found in nature also. The presence of alcohol with the water and turpentine oil facilitates their formation. Thus, a mixture of 1 part of nitric acid, 1 part of alcohol, and 4 parts of turpentine oil, spread out in flat dishes, will yield within a few days crystals amounting to 20 per cent. of the oil taken. If these crystals be fused at 116° C. they will lose water, and *terpin*, $C_{10}H_{18}(OH)_2$, will remain in crystalline needles, fusing at 104° C., and boiling at 258° C. If either of the hydrates just mentioned be boiled with sulphuric, phosphoric, or glacial acetic acid, *terpineol*, $C_{10}H_{17}OH$, will be formed along with hydrocarbons of the formula $C_{10}H_{16}$, such as *terpinene*, *terpinolene*, and *dipentene*. *Terpineol* is a thick, colorless, optically inactive liquid, with a pleasant hyacinthine odor and a bitter, feebly pungent taste. It is used extensively in perfumery. Baeyer (*Ber. Ch. Gesell.*, 26, p. 826) has also prepared the methyl ether of terpineol. Oil of turpentine may be made to yield cymene identical with that existing in the oil of cumin and with that obtained by dehydrating camphor. (See *Cumin Seed*, in PART II.) Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity, owing to the formation of resin. A small proportion of formic acid is said also to be generated. Hence the Edinburgh College directed the oil to be rectified by distilling it with about four measures of water. But the process is difficult, in consequence of the great inflammability of the vapor, and its rapid formation, which causes the liquid to boil over. In this country it is scarcely necessary, as the recent oil can be obtained at an expense less than that which would be incurred by redistillation on a small scale. Another mode of purifying the oil is to agitate it with one-eighth of

alcohol, which dissolves the resinous portion. About one-fifth of the alcohol is retained by the oil, but is readily separated by agitation with water. (See *Oleum Terebinthinæ Rectificatum.*) For tests, see Prof. Fennel, *Proc. A. P. A.*, 1893, 156.

C. T. Kingzett has shown that the atmospheric oxidation of turpentine is accompanied by the formation of a body having the formula $C_{10}H_{14}O_4$, which he regards as *camphoric peroxide*. This substance, by the action of water, is converted into hydrogen peroxide and camphoric acid. The disinfectant known as "*Sanitas*" is produced by passing air through Russian oil of turpentine in contact with warm water. Berthelot has shown that oil of turpentine has, under certain conditions, the power, while undergoing oxidation itself, of causing the oxidation of other bodies, to which it imparts a portion of the oxygen absorbed from the air. All that is necessary to give this power to the oil is that soon after distillation it should be exposed to the air, as in a bottle half filled. Solar light assists, but is not essential to, the change, which goes on even in the dark. The oil retains indefinitely the property thus acquired, but may be deprived of it by exposure to a boiling heat, or by agitation with certain other substances, as potassium pyrogallate. No other chemical or physical change can be detected in the oil. (*Journ. de Pharm.*, Mai, 1860, 351.)

In this country the oil of turpentine is frequently adulterated with petroleum distillates. The adulteration is best detected by the treatment with sulphuric acid followed by steam distillation of the oil layer remaining above the sludge acid; this treatment with acid and after-distillation to be repeated if necessary. The sulphuric acid will thus completely polymerize and resinify the essential oil, leaving the paraffin hydrocarbons unaffected in the residual oily layer. An instance has been put on record in which a sample of the oil, having a pale green color, was found to contain copper. This was easily separated by shaking the oil with a little saturated solution of potassium ferrocyanide and allowing it to stand for two or three days to settle. (C. Lewis Diehl, *A. J. P.*, 1867, 386.)

The several species of pine indigenous to California and the slopes of the Sierra Nevada appear to yield quite different products. Wenzell (*A. J. P.*, March, 1872) described, under the name of *abietene*, an oil distilled from the exudation of the *Pinus sabiniana* (*Nut-Pine* or *Digger-Pine*). He found it to have a sp. gr. of 0·694, and to boil at 101° C. (213·8° F.). Sadtler (*A. J. P.*, April, 1879, p. 176) examined an oil of turpentine from California said to have been obtained from the *Pinus ponderosa* (*Heavy Pine*), and found it to agree substantially with Wenzell's abietene. It had a sp. gr. at 16·5° C. (62° F.) of 0·6974, boiled at 101° C. (213·8° F.), and was slightly lævogyrate. It gave negative results when treated with hydrochloric acid for the formation of a hydrochloride, did not form a hydrate, and was not acted upon by sulphuric acid or by nitrosyl chloride. These anomalous results were at once explained by the publication of a study of the abietene which had been made by Thorpe, who showed (*A. J. P.*, 1879, p. 293) that this exudation of the California pine is almost pure *heptane*, C_7H_{16}, one of the chief constituents of American petroleum. His results were also confirmed by Schorlemmer, who established the identity of the pine heptane with that from petroleum naphtha.

Medical Properties and Uses. Oil of turpentine is stimulant, diuretic, occasionally diaphoretic, anthelmintic, in large doses cathartic, and externally rubefacient. Swallowed in moderate quantities it produces a sense of warmth in the stomach, accelerates the circulation, and increases the heat of the skin, without especially affecting the functions of the brain. In small doses frequently repeated it stimulates the kidneys, augmenting the secretion of urine, and often producing, especially if long continued, painful irritation of the urinary passages, amounting sometimes to violent strangury. At the same time it imparts the odor of violets to the urine; and this effect is also produced by its external application, or even by breathing the air of an apartment impregnated with its vapors. In large doses it occasions slight vertigo, or a sense of fulness in the head, sometimes amounting to intoxication, attended frequently with nausea, and succeeded generally, though not always, by speedy and brisk catharsis. When this effect is experienced, the oil is carried out of the bowels, and, no time being allowed for its absorption, is less apt to irritate the kidneys and bladder than if given in small and repeated doses. In some constitutions it produces, even when taken internally, an erythematous eruption on the skin. Persons who inhale its vapor are liable to strangury and even bloody urine. Hæmaturia is sometimes caused in seamen on board vessels loaded with turpentine. A woman was found dead after having swallowed a large quantity of the oil, probably about six ounces. (*Am. Journ. Med. Sci.*, Oct. 1858.)

The oil is employed in numerous diseases. As a stimulant it sometimes proves serviceable in

low forms of fever. We have found it extremely useful in the advanced stage of *typhoid* or *enteric fever*, and especially in cases in which the tongue has partially or completely thrown off its fur in flakes, and afterwards become dry, with a surface destitute of its ordinary papillary appearance, and often contracted and fissured. The remedy has in our hands proved almost uniformly successful under these circumstances. With small doses of the oil frequently repeated, the tongue becomes moist and again coated, the tympanitic state of the bowels disappears, and the patient goes on to recover as in a favorable case of fever. Its efficiency, however, in typhoid fever is ascribable not so much to its stimulant properties as to an alterative influence upon the ulcerated surface of the bowels characteristic of that disease; and the remedy is often of great service when during the convalescence from typhoid fever diarrhœa due to slow healing of the ulcers occurs. In *chronic rheumatism*, particularly *sciatica* and *lumbago*, the oil has often been given with great benefit. It has also been much extolled as a remedy in some forms of *puerperal fever*, in *neuralgia*, in *passive hemorrhages*, particularly from the bowels, in *chronic dysentery* and *diarrhœa*, in obstinate *gleets* and *leucorrhœa*, in *retention* and *incontinence of urine* from debility, in *chronic nephritic* and *calculous affections*, and in various conditions of *whooping-cough*. In certain cases of *dysentery*, whether acute or chronic, when the tongue is quite dry, and smooth as if from defect of the papillary structure, no remedy has proved so efficient in our hands as oil of turpentine. We have seen it also very beneficial in *hæmoptysis*. As a vermifuge it is highly esteemed, especially in cases of *tænia*. It appears to destroy or debilitate the worm, which, losing its hold upon the bowels, is then easily discharged. In cases of *worms in the stomach* it is very useful, and in *amenorrhœa* from torpor of the uterine vessels it is occasionally of service. (*A. J. P.*, March, 1869.)

The dose for ordinary purposes is from five to thirty drops (0·3–1·9 C.c.), repeated every hour or two in acute, and three or four times a day in chronic diseases. In rheumatism it is recommended by some in the dose of a fluidrachm (3·75 C.c.) every four hours. As a remedy for tape-worm the dose is from one-half to one fluidounce, followed by castor oil in half an hour. It has also proved successful in tænia in the dose of half a drachm (1·9 C.c.), twice a day, continued for a considerable time. In ordinary cases of worms, the usual dose may be given. It may be administered on sugar, or in emulsion with gum arabic, loaf-sugar, and cinnamon- or mint-water. As to some its taste is very disagreeable, it may be given in capsules.*

In the form of enema, the oil is highly useful in cases of *ascarides*, of *obstinate constipation*, and especially of *tympanites*. From half a fluidounce to two fluidounces (15–60 C.c.) may be administered in some mucilaginous fluid.

Externally applied, oil of turpentine irritates and speedily inflames the skin, and is one of the most efficacious rubefacients: it is used in *rheumatic affections*, and in various internal inflammations. When only a slight impression is desired, it may be diluted with olive oil; but in some constitutions, even in this state, it produces such violent inflammation of the skin, with extensive eruptions, as to render its external use in any shape improper. Applied to recent *burns*, it is thought by some to be highly useful in allaying the burning pain and promoting a disposition to heal. For this purpose, however, it is usually mixed with resin cerate (*basilicon ointment*), so as to form a liniment capable of being spread upon linen rags. (See *Linimentum Terebinthinæ*.)† M. Beullard has found it useful in *eczema*, applied directly to the affected part. It causes immediately severe pain and much swelling, and in a few minutes must be removed, and followed by cooling and demulcent measures. A modification of the disease is thus produced, which renders ordinary applications successful that had been previously useless. (*Ann. de Thérap.*, 1865, p. 138.) It is thought by Profs. Von Erlach and Lucke, of Berne, to be peculiarly efficacious in *parasitic affections* of the scalp, by destroying the parasites and preventing the development of the spores. (*Am. Journ. of Med. Sci.*, July, 1869, p. 248.)

Oil of turpentine has been recommended, in the form of bath, in affections in which its constitutional impression is desired. For this purpose Dr. T. Smith, of Cheltenham, England, employs from five to ten fluidounces of the oil, with half a fluidounce of oil of rosemary, and

* It has been objected to the form of capsule, that, in consequence of the breaking of its coating, the oil may come undiluted in contact with the mucous membrane, and thus produce undue irritation. M. Lacambre gives the following process for making a pill of the oil. Take of oil of turpentine 8 grammes, white wax 20 ditto, powdered sugar 9 ditto, oil of lemon 2 drops. Melt the wax in the oil of turpentine, pour into a mortar, allow to cool, then add the sugar, and form a mass to be divided into pills of 25 centigrammes (3 or 4 grs.) each. Roll them in powdered starch, and keep in a well-stopped bottle. (*Journ. de Pharm.*, Sept. 1873, p. 223.)

† The following is the formula adopted by the Philadelphia College of Pharmacy for the rubefacient liniment known as *British Oil*. ℞ Olei Terebinth. f℥viij, Olei Lini f℥viij, Olei Succini f℥iv, Olei Juniperi f℥iv, Petrolei Barbadensis f℥iij, Petrolei Americani (crude petroleum) f℥j. M.

two pounds of sodium carbonate, in each bath. The breath becomes strongly impregnated with the terebinthinate odor. (*Braithwaite's Retrospect*, xxi. 355.) Applied in vapor, the oil is said to be a very speedy cure for the *itch*. The bed- and night-clothes are sprinkled with thirteen drachms of the oil, and on awaking in the morning the patient finds himself cured. (*Am. Journ. of Med. Sci.*, July, 1857, p. 232.) Baths of the vapor of turpentine are stated to be very beneficial in chronic rheumatism. They are said to be borne well, for twenty-five minutes, at a temperature of from 60° to 71·1° C. (140°–160° F.). (*Arch. Gén.*, 4e sér., xxviii. 80.) Inhalation of the vapor has been recommended by Skoda in gangrene of the lungs.

OLEUM TEREBINTHINÆ RECTIFICATUM. U. S. Rectified Oil of Turpentine.

(Ō'LḘ-ŬM TḚR-Ḛ-BĬN'THI-NÆ RḚC-TI-FI-CĀ'TŬM.)

"Oil of Turpentine, *a convenient quantity;* Lime Water, *a sufficient quantity.* Shake the Oil thoroughly with *six times* its volume of Lime Water, and introduce the mixture into a copper still connected with a well-cooled condenser. Then distil, until about *three-fourths* of the Oil have passed over, and separate the clear Oil from the water. Keep the product in well-stoppered bottles, in a cool place, protected from light. Rectified Oil of Turpentine should always be dispensed when Oil of Turpentine is required for internal use." *U. S.*

When oil of turpentine is distilled in contact with lime water, the distillate comes over purified and freed from the products which give the commercial oil the disagreeable odor and taste which are inseparable by ordinary distillation: hence this rectified oil is much preferable for internal administration. It has in other respects the same properties as Oleum Terebinthinæ. "Specific gravity, 0·855 to 0·865 at 15° C. (59° F.). Boiling point, about 160° C. (320° F.). Its alcoholic solution should be neutral to litmus paper. If 10 C.c. of the Oil be evaporated in a capsule on a water-bath, not more than 0·05 Gm. of residue should be left." *U. S.* For observations on the rectification of oil of turpentine, by Prof. Kremers, see *Pharm. Rev.*, 1897, 7.

OLEUM THEOBROMATIS. U. S., Br. Oil of Theobroma.

(Ō'LḘ-ŬM THḚ-Ọ-BRŌ'MA-TĬS.)

"A fixed oil expressed from the seed of Theobroma Cacao, Linné (nat. ord. Sterculiaceæ)." *U. S.* "A concrete oil obtained by pressing the warm crushed seeds of Theobroma Cacao, Linn." *Br.*

Oleum Theobromæ, *U. S.* 1880; Cacao Butter; Oleum (Butyrum) Cacao, *P. G.;* Beurre de Cacao, *Fr.;* Kakaobutter, *G.*

Theobroma cacao. Linn. *Sp. Plant.* 1100; Hayne, *Darstell. und Beschreib.*, etc., ix. 35; *B. & T.* 38. This is a handsome tree, from twelve to twenty feet in height, growing in Mexico, the West Indies, and South America. It is largely cultivated in all tropical countries, particularly in Guayaquil, Venezuela, Mexico, Trinidad, and the Philippines. The fruit is an oblong-ovate capsule or berry, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the *cacao*, or *chocolate nuts*, of commerce. The cacao-tree is usually cultivated in large estates, where it is grown in the shade of the banana or other large plant, and develops its pods from the stem continually, so that the harvest goes on all the time, although the product is greater in the spring and in the autumn. The pods are cut off, opened, and the beans contained in the glutinous sweet acid pulp are allowed to ferment, during which process the outer integument comes off and falls loose. The beans are finally carefully dried, commonly in the sun, sometimes by means of a steam-drying shed. If the sweating process is carried too far, or the beans during drying are wetted by rain, they blacken and are much lowered in value. These blackened beans are sometimes artificially whitened. Cacao beans have a slightly aromatic, bitterish, oily taste, and, when bruised or heated, an agreeable odor.

The average of a number of analyses of raw nuts gave H. Weigmann (*König's Nahrungs- und Genussmittel*, 3d ed., vol. i. 1019) water, 7·93 per cent.; nitrogenous matter, 14·19 per cent.; theobromine, 1·49 per cent.; fatty matter (cacao butter), 45·57 per cent.; starch and other carbohydrates, 22·92 per cent.; crude fibre, 4·78 per cent.; pure ash, 3·99 per cent.; sand, 0·62 per cent. The coloring matter is probably the result of chemical change, as the fresh seeds are white. Theobromine has been found also in the shells in the proportion of about 1 per cent. (*A. J. P.*, 1862, 509.) The latter impart to boiling

water a taste analogous to that of chocolate, but weaker, and are used for making a table beverage.

Theobromine was discovered by M. Woskresensky, who obtained it by the following method. The kernels are exhausted with water by means of the water-bath; the solution is strained through linen, precipitated by lead acetate, and filtered; the filtered liquor is freed from lead by hydrogen sulphide, and evaporated; the brown residue is treated with boiling alcohol, and the liquor filtered while hot. Upon cooling, the theobromine is deposited in the form of a reddish-white powder, which is rendered colorless by repeated crystallization. Keller obtained it still purer by heating the powder between two watch-glasses, by which a brilliant white sublimate was obtained. According to O. Donker and C. Treumann, theobromine is contained not only in the cotyledons but also in the shells of the cacao seeds. Four kilos of the latter yielded 13·5 Gm. of pure theobromine. (*Archiv der Pharmacie*, July, 1878.) Theobromine is a crystallizable alkaloid, capable of forming salts with the acids, very bitter, volatilizable without change, freely soluble in hot alcohol, sparingly so in hot water, and is very simply related to caffeine, this latter being the methyl derivative of theobromine. Its formula is $C_7H_8N_4O_2$. It has been converted into caffeine by Strecker, and more recently E. Fischer (*Ber. Chem. Ges.*, 1882, p. 453) has obtained it from xanthine, $C_5H_4N_4O_2$, which is easily obtained from the guanine of guano, $C_5H_5N_5O$, by the action of nitrous acid. For Emminger's method of determining theobromine in cacao, see *P. J. Tr.*, 1896, 289.

Chocolate is differently prepared in different countries. In Great Britain and the United States it usually consists, when pure, exclusively of the kernel of the cacao or chocolate nuts, which are first roasted, then deprived of their shell, and lastly reduced, by grinding between heated stones, to a paste, which is moulded into oblong cakes. Not unfrequently rice flour or other farinaceous substance, with butter or lard, is added; but these must be considered as adulterations. On the continent of Europe, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added. Vanilla is a favorite addition in South America, France, and Spain. Cacao, called *cocoa*, is often sold in powder, which is sometimes mingled with other ingredients, such as ground rice, barley-flour, sugar, etc. Chocolate is prepared for use by reducing it to powder and boiling it in milk, water, or a mixture of these fluids. In this state it is much employed as a drink at breakfast and tea, and serves as a substitute for coffee in dyspepsia. It is also a good article of diet for convalescents, and may sometimes be given advantageously as a mild nutritive drink in acute diseases. Hagenbuch examined several commercial brands of chocolate, and found that the amount of fat or cacao butter present varied from 12 to 45·8 per cent. (*A. J. P.*, 1885, p. 276.) From this it would seem that manufacturers do not uniformly extract the fat from commercial chocolate.

Oil of Theobroma. Cacao Butter. This is the fixed oil of the chocolate nut. It is extracted either by expression, decoction, or the action of a solvent. Soubeiran recommends that the seeds, previously ground, be mixed with one-tenth of their weight of water and then pressed between hot plates of tinned iron. It is advisable that the heat should not exceed that of boiling water, and even a lower heat will answer. When the method of decoction is used, the cacao should be slightly roasted before boiling. As a solvent, carbon disulphide has been found to answer well, as recommended in the preparation of the expressed oil of nutmeg. (See *Oleum Myristicæ*.) Upon the whole, the method of expression is perhaps preferable. The presence of water in the ground seeds is said greatly to facilitate the process. The expressed oil, which is now made in Philadelphia, occurs in the shape of oblong cakes, like those of chocolate, weighing about half a pound each. It is "a yellowish-white solid, having a faint, agreeable odor, and a bland, chocolate-like taste. Specific gravity, 0·970 to 0·980 at 15° C. (59° F.). Readily soluble in ether or chloroform; also soluble in 100 parts of cold and in 20 parts of boiling absolute alcohol, all these solutions being neutral to litmus paper. It is brittle at 15° C. (59° F.), and melts at 30° to 33° C. (86° to 91·4° F.) to a clear liquid. If 1 Gm. of Oil of Theobroma be dissolved in 3 C.c. of ether, in a test-tube, at a temperature of 17° C. (63° F.), and the tube subsequently plunged into water at 0° C. (32° F.), the liquid should not become turbid, nor deposit a granular mass in less than three minutes; and if the mixture, after congealing, be exposed to a temperature of 15° C. (59° F.), it should gradually form a perfectly clear liquid (absence of *paraffin*, *wax*, *stearin*, *tallow*, etc.)." *U. S.* "A yellowish-white solid, breaking with a smooth fracture; odor resembling that of cocoa; taste bland and agreeable; free from rancidity. It softens at 80° F. (26·6° C.) and melts at temperatures between 88° and 93° F. (31·1° and 33·9° C.). If 1 gramme be dissolved in 3 cubic centimetres of *ether*, in a test-tube, at 62° or 63° F. (or 17° C.), and the tube be placed in water

at 32° F. (0° C.), the liquid should neither become turbid nor deposit a granular mass in less than three minutes; and if the mixture after congealing be exposed to a temperature of 60° F. (15·5° C.) it should gradually afford a clear solution (absence of other fats)." *Br.* Cacao butter consists chiefly of the glycerides of stearic, palmitic, and lauric acids, and, further, of small quantities of the glycerides of arachidic, linolic, formic, acetic, and butyric acids. The percentage of stearic acid obtainable is from 39·9 to 40·6. Kingzett believes it to contain in addition a peculiar acid which he calls *theobromic*, and to which he gives the formula $C_{64}H_{128}O_2$, but his results have not been confirmed by subsequent investigators. From its large proportion of stearin, it is one of the best fats for the preparation of stearic acid. It is said to be frequently adulterated with animal fats, which, according to Mr. E. Lamhofer, may be detected by attention to the fact that pure cacao butter dissolves entirely in ether or benzin, separating out in minute granular crystals when immersed in water of 0° C. (32° F.), the liquid portion remaining transparent for 30 or 40 minutes, when the whole solidifies. After solidification, if the oil be kept at a temperature of about 14·4° C. (58° F.), it will redissolve without turbidity. (*A. J. P.*, 1877, p. 238.) Mr. G. Ramsperger concludes, as the result of much experimentation, that ether affords the best test of purity. Dissolving the suspected cacao butter in 2 parts of ether, if it become turbid after standing, or form on spontaneous evaporation little crystals or grains not soluble in 2 parts of ether at common temperature, it is impure, and should be rejected.

Butter of cacao is used as an ingredient in cosmetic ointments, and in pharmacy for coating pills and preparing suppositories. For the last purpose it is well adapted by its consistence and blandness, and is now largely consumed. It was, indeed, on this account chiefly that it was introduced into the U. S. Pharmacopœia of 1860.* F. Bringhurst prepared a lip salve by melting together 28 ounces of cacao butter, 4 ounces of yellow wax, and a drachm, each, of balsam of Peru and benzoic acid, straining, adding perfuming oils, as those of rose, bergamot, and bitter almond, in sufficient quantity, and finally, when nearly cool, an ounce of glycerin. (*A. J. P.*, July, 1867, p. 348.)

Owing to its great insolubility, pure theobromine acts very slowly and uncertainly upon the animal organism, but its soluble salts (notably the *salicylate of sodium and theobromine*†) are active diuretics, which have been used to a considerable extent with general commendation in the treatment of various dropsies. They are said not to irritate the kidneys, and have been even highly commended not only in *chronic* but even in *acute Bright's disease.* They seem to act directly upon the renal secreting structure, but their physiological activity has not been sufficiently studied to determine positively their cardiac action: various observers affirm, others deny, that they are heart-stimulants, with the preponderance of evidence in favor of their having very little, if any, effect upon the circulation. Usually their action is very favorable; but headache, irregularity of the pulse, vomiting, and diarrhœa have been noticed in various cases, and, according to W. Schmieden, hæmaturia. Dose, from ten to twenty grains (0·65–1·3 Gm.), from four to six times a day, administered in capsules or in solution.

OLEUM THYMI. U. S. Oil of Thyme.

(Ō'LḘ-ŬM THĪ'MĪ.)

"A volatile oil distilled from the leaves and flowering tops of Thymus vulgaris, Linné (nat. ord. Labiatæ)." *U. S.*

Essence de Thym, *Fr.*; Thymianöl, *G.*

In the south of France thyme grows wild in great abundance, and is largely collected for distillation. The oil is taken from France to England, and thence reaches this country under the name of *oil of origanum*, having, probably from its greater cheapness, been substituted for the genuine oil. For all the purposes for which oil of origanum was used, that of thyme is not less useful, and it is more agreeable.

* *Mafurra Tallow.* This is a fatty matter obtained from the fruit of a tree growing in Mozambique and the islands of Madagascar and Bourbon, and bearing a close resemblance in qualities to cacao butter. The kernel of the fruit is described as of the size of the cacao bean, having the same characteristic odor when bruised, and a bitter taste. The fatty matter is extracted by boiling the kernels in water. It is of a firm, solid consistence, less fusible than tallow, of a yellowish color, and of the odor of cacao butter. It agrees, moreover, with that substance in containing olein and palmitin, and yields palmitic acid largely when saponified. (*A. J. P.*, xxviii. 163.)

† A mixture of a compound of sodium, theobromine, and sodium salicylate has been introduced into medicine under the trade name of *diuretin*. It is a white powder, soluble in less than half its weight of water when warmed. It should contain 49·7 per cent. of theobromine and 38·1 per cent. of salicylic acid.

Thymus vulgaris is a very common plant, indigenous to the south of Europe, and cultivated in our gardens. It possesses a subcampanulate two-lipped calyx, villous in the throat; corolla limb two-lipped, the upper erect and emarginate, the lower spreading, three-cleft. It is a low under-shrub, procumbent at the base, with ovate-linear, revolute leaves, and flowers in a whorled spike. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odor, not lost by drying, and a pungent, aromatic, camphorous taste. Its active constituent is the volatile oil, which is obtained separate by distillation with water.

The oil, as prepared in the south of France, is, after one distillation, of a reddish-brown color, and called the *red oil*, but when again distilled is colorless, and in this condition is distinguished as the *white oil*. It is officially described as "a yellowish or yellowish-red liquid, having a strong odor of thyme, and an aromatic, pungent, afterwards cooling taste. It becomes darker and thicker by age and exposure to the air. Specific gravity, 0·900 to 0·930 at 15° C. (59° F.). It does not fulminate with iodine. The Oil is soluble in half its volume of alcohol, forming a clear solution which is neutral or only very slightly acid to litmus paper. The Oil is also soluble, in all proportions, in carbon disulphide, and in glacial acetic acid. With a drop of ferric chloride test-solution the Oil yields a greenish-brown color, which changes to reddish. If 1 C.c. of the Oil be shaken with 10 C.c. of hot water, and, after cooling, the liquid be passed through a wet filter, the filtrate should not assume, with a drop of ferric chloride test-solution, a bluish or violet color (absence of *carbolic acid*)." *U. S.* According to Zeller, one pound of the fresh herb yields 45·7 grains of the oil, of the dried herb 38 grains. The oil, as found in commerce, is of a reddish-brown color, and of an odor recalling that of thyme, but less agreeable. Its sp. gr. is stated at 0·905, but probably varies, as the oil is a complex body. The more volatile portion, that coming over below 180° C. (356° F.) in distillation, is a mixture of *cymene*, $C_{10}H_{14}$, boiling at 175° C. (347° F.), and *pinene*, $C_{10}H_{16}$, boiling at 161° C. (321·8° F.). The less volatile portion is chiefly *thymol*, $C_{10}H_{14}O$, a white crystalline solid, melting at 44° C. (111·2° F.), and possessing a pungent taste. (See *Thymol.*) *Carvacrol* is also present, at times replacing part or all of the thymol, and in addition *linalool* and *bornyl acetate* have been found in small amount. (See *Proc. A. P. A.*, 1897, 637.) The annual production of oil of thyme at Grasse, according to Flückiger (*A. J. P.*, 1885, 132), amounts to 40,000 kilogrammes. According to Camperdon, in doses of from three to fifteen grains oil of thyme causes mental excitement, and is a valuable diffusible stimulant in *collapse*. It is certainly an antiseptic. (See *Thymol.*)

OLEUM TIGLII. U. S. (Br.) Croton Oil.

(Ō'LḘ-ŬM TĬG'LI-Ī.)

"A fixed oil expressed from the seed of Croton Tiglium, Linné (nat. ord. Euphorbiaceæ)." *U. S.* "The oil expressed from the seeds of Croton Tiglium, Linn." *Br.*

Oleum Crotonis, *Br.;* Huile de Croton, Huile de Graines de Tilly, *Fr.;* Crotonöl, *G.;* Nervalum unnay, *Tamil.*

Croton tiglium. Willd. *Sp. Plant.* iv. 543; *B. & T.* 239. This species of Croton is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a dark-green color on the upper surface, paler beneath, and furnished with two glands at the base. The flowers are in erect terminal racemes, scarcely as long as the leaf,—the lower being female, the upper male, with straw-colored petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, the Moluccas, and other parts of India. It is pervaded by an acrid purgative principle, probably analogous to that found in other plants belonging to the family of Euphorbiaceæ. Rumphius says that the root is employed in Amboyna, in the dose of a few grains, as a drastic purge in dropsy; and, according to the same author, the leaves are so acrid that when chewed and swallowed they excite inflammation in the lips, mouth, and throat, and along the whole course of the alimentary canal. The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the most active part. These have been long used in India as a powerful purgative, and were employed so early as 1630 in Europe, under the names of *grana Molucca* and *grana tiglia*. But in consequence of their violent effects they fell into neglect, and had ceased to be ranked among medicines, when, at a comparatively recent period, attention was again called to them by the writings of some English physicians in India. They are now imported for their oil, which is the only official product of the plant. It is probable that most if not all of the Crotons are purgatives. The oil of the Mexican *Croton morifolius* is said to be mildly purgative in

doses of two or three drops. In India, under the name of *Kowli seeds* (*Kuli seeds*),* are used certain beans, which have been referred by authorities to the *Croton oblongifolium*, Roxb., and also to the *C. persimilis*, Müll.-Arg. (See *Pharm. Rev.*, Oct. 1896.)

These seeds are rather larger than a grain of coffee, oblong, rounded at the extremities, with two faces, the external considerably more convex than the internal, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes, as in the coffee-grain, their internal surface is flat, with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft, yellowish-brown epidermis, beneath which the surface is black and smooth; and, as the epidermis is often partially removed by friction during their carriage, the seeds as they come to us are frequently mottled, and sometimes nearly black. The kernel or nucleus is yellowish brown, and abounds in oil. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable. In the dose of one or two grains (0·065 or 0·13 Gm.) the kernel purges severely.

The oil is obtained by expression from the seeds, previously deprived of the shell. It may also be separated by decoction in water, or by the action of ether, or carbon disulphide, which dissolves the oil, and leaves it behind when evaporated.† Guibourt recommends, after the first expression, to digest the residue with alcohol at a temperature of 48·8° to 60° C. (120° to 140° F.), and then submit it to a new expression. The alcohol is to be separated by distillation from the oil, which is then to be mixed with the first product. According to Dr. Nimmo, the seeds consist of 64 per cent. of kernel and 36 of envelope. From the seeds imported into England, about 22 per cent. of oil is obtained by simple expression. Guibourt, by his process, obtained 52 per cent. from the kernels, equivalent to about 35 per cent. from the seeds. Croton oil consists chiefly of the glycerides of stearic, palmitic, myristic, lauric, and oleic acids. There are also present, in the form of glycerin ethers, the more volatile acids, as formic, acetic, isobutyric, and isovalerianic acids. The volatile part of the acid yielded by croton oil contains, moreover, an acid of the oleic series, named by Geuther and Frölich *tiglic* or *tiglinic acid*, $C_5H_8O_2$. It is isomeric with angelic acid, but the melting points (angelic acid 45° C., tiglic acid 64° C.) and the boiling points (angelic acid 185° C., tiglic acid 198·5° C.) differ. *Crotonic acid*, $C_4H_6O_2$, was thought by Schlippe to be present, but later investigation does not confirm the statement. *Crotonol*, announced by Schlippe as the vesicating principle of the oil, has likewise been found only by the discoverer.

In 1823 Dr. John Nimmo, of Glasgow, found that about 45 per cent. of croton oil is soluble in alcohol, the insoluble 55 per cent. being inert. Recent researches have shown that the percentage of soluble portion varies greatly. (See also below.) According to Senier, confirmed by Binz, Kobert, and others, it increases with the age, freshly expressed oil containing only 20 per cent., oil over four years old 60 per cent. In this soluble portion Buchheim found an acid, *crotonolic acid* or *crotonoleic acid*,‡ which he believed to be the active principle. It is an oily substance, readily decomposable, having the character of a weak acid, and forming various salts. It is freely soluble in alcohol, and is extremely irritant to the skin and the mucous

* Kowli seeds reach a length of two and one-tenth Cm., a breadth of one and two-tenths Cm., a thickness of eight-tenths Cm., ovate, having pointed ends with a marked caruncle. The outer side shows the grayish-brown crusty seed-coat with irregular rough longitudinal stripes; the cross-section shows a large endosperm, in the middle the embryo of considerable size with flat cotyledons. Besides the fatty oil and protoplasm, the cells of the endosperm show longitudinally very large aleurone grains, which contain a considerable number of small globoids and badly formed crystalloids.

† *Extraction by ether.* Having washed and dried the seeds, grind them in a coffee-mill, and form a soft paste with ether. Introduce this into a narrow percolation tube, and gradually pour ether upon it until it is exhausted. Evaporate the ether by means of a water-bath, and filter the remaining oil. (*Journ. de Pharm.*, Août, 1862.)

Extraction with carbon disulphide. The seeds, well bruised, are introduced into a bottle with three times their weight of carbon disulphide, well rectified; the mixture is allowed to stand, with frequent agitation, for 24 hours; the whole is then poured upon a cloth and rapidly expressed. The residue is similarly treated with twice its weight of the disulphide, and expressed, after standing as before. The products of the two macerations are mixed, then filtered in a covered funnel, and finally submitted to distillation, by means of a water-bath, in a glass retort, at the temperature of 71·1° or 76·6° C. (160° or 170° F.). The disulphide should be recovered by condensing its vapor in a refrigerated receiver. The oil is to be poured into a capsule, to show that it contains none of the disulphide, and then introduced into a bottle. (*Journ. de Pharm.*, 3e sér., xxxi. 28.)

‡ *Crotonoleic acid* may be readily prepared by treating the portion of croton oil soluble in alcohol with a hot saturated solution of baryta in a water-bath, washing the stiff white paste that forms with cold distilled water to remove excess of baryta and barium compounds with acetic, butyric, and tiglic acids, repeatedly treating with water, and lastly agitating with ether, which takes up only the barium oleate and crotonoleate. The crotonoleate is separated by dissolving it out in alcohol, decomposed carefully with sulphuric acid, and the solution containing the free acids evaporated. For further details, see *Kobert's Arbeiten*, 1890, p. 30.

membranes. As pointed out in 1889 by Stillmark and Kobert, croton seeds contain one or more toxic albuminoids, which have been especially studied under the name of *crotin* by M. Elfstrand.* Dunstan and Boole (*Proc. Roy. Soc. London*, lxiii., 1895) found that crotonoleic acid prepared by the method of Kobert and Hirscheydt is a mixture of inactive oily acids and a resinous substance, having extraordinary power as a vesicant, for which they have proposed the name of *croton-resin*, assigning to it the empirical formula $C_{13}H_{18}O_4$, and the molecular formula $(C_{13}H_{18}O_4)_2$, or $C_{26}H_{36}O_8$. It is described as a hard, pale yellow resin, nearly insoluble in water and benzene, but readily dissolved by alcohol, ether, and chloroform. It is neither a glyceride, a ketone, nor an aldehyde.

Properties. Croton oil, as found in commerce, varies from a pale yellow to a dark reddish brown. That imported from India is usually pale, that expressed in Europe dark, like the deepest-colored sherry. Its consistence is rather viscid, and is increased by time. Its smell is faint, but peculiar, its taste hot and acrid, leaving in the mouth a disagreeable sensation which continues for many hours. "Specific gravity, 0·940 to 0·960 at 15° C. (59° F.). It reddens blue litmus paper moistened with alcohol. When fresh, it is soluble in about 60 parts of alcohol, the solubility increasing by age. It is freely soluble in ether, chloroform, carbon disulphide, and in fixed or volatile oils. When gently heated with twice its volume of absolute alcohol, it forms a clear solution from which the Oil usually separates on cooling. If to 2 C.c. of the Oil 1 C.c. of fuming nitric acid and 1 C.c of water be added, and the mixture vigorously shaken, it should not solidify, either completely or partially, after standing for one or two days (absence of *other non-drying oils*)." *U. S.* "Specific gravity 0·940 to 0·960. Entirely soluble in *absolute alcohol*. Freely soluble in *ether* and *chloroform*. An alcoholic solution should not redden moistened *blue litmus paper*. If to 2 cubic centimetres 1 cubic centimetre of *fuming nitric acid* and 1 of *water* be added, and the mixture be shaken vigorously, it should not solidify, either completely or partially, but only thicken slightly, after standing for two days (absence of other non-drying oils)." *Br.* The oil is wholly soluble in ether and oil of turpentine. Its relations to pure alcohol differ somewhat with the variety of the oil. That obtained by expression in England was formerly wholly and readily soluble, but, according to Mr. Harold Senier, the croton oil now produced acts towards alcohol as do foreign oils (*P. J. Tr.*, 3d ser., xiv. 704), forming a solution which is permanent at ordinary temperatures, while the India or pale oil forms an opaque mixture, which becomes clear and uniform upon being heated, but separates on standing into two portions, one consisting of alcohol somewhat diminished in bulk, the other of the oil correspondingly increased in bulk by retaining a portion of the alcohol. It is probable that the difference in color, and in their relations to alcohol, between the India and English oils may be owing to a change in the kernels from being kept, and to the age of the oil. It is thought that croton oil is often adulterated with other fixed oils. In the Br. Pharm. of 1864 it was given as a test of the purity of the oil expressed from the imported seeds, that when agitated with an equal volume of alcohol and gently heated it forms a clear solution, from which about three-fourths of the oil separates on cooling; but the statement is asserted to be untrue of the English expressed oil, though correct of the imported. The test was intended to detect the presence of castor oil, which would be dissolved by the alcohol and thus occasion a diminution of the bulk. It has been omitted in the present Pharmacopœia.† For tests for croton oil, including iodine and acid numbers, see *Pharm. Rev.*, 1897, 113.

According to the late Dr. M. Burrough, who was for some time in India, much of the oil there prepared is derived from the seeds of *Jatropha curcas*, or *Curcas purgans*, the so-called *Barbadoes nuts*. This oil, though weaker than the genuine, was said by Dr. Burrough to be an efficient cathartic in the dose of three or four drops (0·18 or 0·24 C.c.). Dr. Hamilton states that croton seeds are afforded by *Croton pavana*, growing in Ava and Bengal; and probably a portion of the croton oil of commerce is obtained from these seeds. These facts may explain some of the discrepancies which have been observed in the effects of alcohol.

Medical Properties and Uses. Croton oil is a powerful drastic purgative, in large doses apt to excite vomiting and severe griping pains, and capable, if immoderately taken, of

* Crotin is described as a yellowish powder, yielding about 21 per cent. of ash, soluble in water, and possessed of such active poisonous properties that the subcutaneous lethal dose for the rabbit is from 0·05 to 0·08 Gm. per kilo. It attacks the blood-corpuscles as well as the centric nervous system, and, indeed, probably affects all protoplasm. (*On Some Toxic Albumins*, Upsala, 1897.)

† Prof. Maisch detects croton oil in any mixture by the following plan. The suspected oil is agitated with an alcoholic solution of soda or potassa, and the solution, having been separated, is saturated with hydrochloric or sulphuric acid. If croton oil be present its acrid principle will rise to the surface in the form of an oil, which when applied to the skin will produce the peculiar eruptive affection excited by croton oil. (*A. J. P.*, 1860, 307.)

producing fatal effects. It acts with great rapidity, frequently evacuating the bowels in less than an hour, and generally exciting a rumbling sensation in half that period. It possesses also great advantage in the minuteness of the dose, on account of which it may frequently be given when we should fail with more bulky medicines, as in *mania*, *coma*, and the cases of children. A drop placed on the tongue of a comatose patient will generally operate. Though long used in India, and known for two centuries to the Dutch physicians, it did not attract general notice till about 1820, when it was introduced into England by Mr. Conwell. It is chiefly employed in cases of *obstinate constipation*, in which it often produces the happiest effects after the failure of other medicines; but it may also be advantageously used in almost all cases in which powerful and speedy purging is demanded, especially where an irritation of the gastric mucous membrane and a derivative action are desired. The seeds are said to have been used with great success in India in *amenorrhœa*. Applied externally, the oil produces inflammation of the skin, attended with pustular eruption, and has been used in this way in *rheumatism*, *gout*, *neuralgia*, *glandular* and other *indolent swellings*, and *laryngeal* and *pulmonary diseases*. It should be diluted with three parts of olive oil, soap liniment, oil of turpentine, or other convenient vehicle, and applied as a liniment twice or oftener in twenty-four hours. Sometimes the insusceptibility of the skin is such as to require its application undiluted. The oil may also be applied externally, in the form of a plaster, made by incorporating one part of it with four parts of lead plaster, melted by a very gentle heat. Sometimes it appears to produce inflammation in parts distant from those to which it was directly applied. It has been said that four drops, used externally by friction around the umbilicus, will produce a purgative effect, but this is denied by Dr. Barlai, of Tuscany, who states that it is only when the oil is applied to the skin divested of the cuticle that it will operate upon the bowels. *Nævus* has been cured by the introduction of croton oil into the little tumor by means of needles.* The dose for an adult is one or two drops (0·06 or 0·12 C.c.), and is most conveniently administered in the form of pill. A safe and convenient plan is to make two drops into four pills with crumb of bread, and to give one every hour till they operate. The oil may also be given in capsules, cachets, emulsion, or in tincture.

Crotonoleic acid has been shown by Kobert to be a very active irritant poison, much more harsh and severe in its influence than croton oil itself. Hirschheydt has found that its salts injected into the blood are extremely powerful depressants to the circulation. It has appeared in commerce, but after trial has been found by Hirschheydt to act badly as a practical remedy. It probably also varies greatly in purity. Ten milligrammes were found by Hirschheydt to be very uncertain in their purgative effect, whilst large doses commonly produced excessive gastro-intestinal irritation. The superiority of croton oil over the acid probably depends upon the fact that the acid exists in it chiefly in combination with glycerin, and that this crotonoleic glyceride acts with comparative kindness because of the slow decomposition and setting free of the acid which occur in the intestines. This being the case, it follows as a corollary that old, acid croton oil must be more irritant than the fresher and nearly neutral oil. Professor Kobert has confirmed this conclusion by actual trial, and asserts that the neutral oil should always be preferred in practice, and that the acid oil, which is official in the German Pharmacopœia, should be rejected.

OPII PULVIS. U. S. Powdered Opium.

(Ō'PI-Ī PŬL'VĬS.)

"Opium, dried at a temperature not exceeding 85° C. (185° F.), and reduced to a very fine (No. 80) powder. Powdered Opium, for pharmaceutical or medicinal purposes, when assayed by the process given under Opium, should yield not less than *thirteen* nor more than *fifteen per cent.* of crystallized morphine. Any Powdered Opium of a higher percentage may be brought within these limits by admixture with Powdered Opium of a lower percentage, in proper proportions." *U. S.*

The strength of powdered opium has not been materially altered in the last revision, the only change being in the maximum limit, 16 per cent. in the U. S. P. 1880 becoming 15 per cent. in the present. It is easy to obtain powdered opium fully meeting these requirements.

* *Croton Oil Crayons.* In order to prevent the spreading of croton oil beyond the limits intended, Limousin prepared crayons by melting 1 part each of cacao butter and white wax in a small glass flask, and then adding 2 parts of croton oil, taking care to close the orifice of the flask at once with a cork. When the mixture begins to get thick, it is poured into cylindrical moulds, where it speedily solidifies. These crayons may be made of a thickness of about 8 or 9 millimetres (⅓ inch), and may be covered with tin foil. (*N. R.*, May, 1877.)

OPIUM. U. S., Br. Opium.

(Ō'PI-ŬM.)

"The concrete, milky exudation obtained by incising the unripe capsules of Papaver somniferum, Linné (nat. ord. Papaveraceæ), and yielding, in its normal, moist condition, not less than *nine per cent.* of crystallized morphine, when assayed by the process given below [see page 997]." *U. S.* "The juice obtained by incision from the unripe capsules of Papaver somniferum, Linn., inspissated by spontaneous evaporation. Any suitable variety of opium may be employed as a source of Tincture of Opium and Extract of Opium of the respective official alkaloidal strengths, provided that when dry it contains not less than 7½ per cent. of anhydrous morphine; but, when otherwise used for officially recognized purposes, opium must be of such a strength that when dried, and powdered, the powder heated to 212° F. (100° C.) until it ceases to lose moisture, and the product tested by the appended method, such dry powder shall yield not less than 9½ per cent., and not more than 10½ per cent., of anhydrous morphine. Opium yielding when dried more than 10 per cent. of anhydrous morphine may be diluted to that percentage with any opium containing when dry between 7½ and 10 per cent. of anhydrous morphine, or with Milk Sugar." *Br.*

Meconium, Succus Thebaicus, Thebaica; Opium, *Fr.;* Opium, Mohnsaft, *G.;* Oppio, *It.;* Opio, *Sp.;* Affioni, *Turk.;* Ufyoon, *Arab.;* Sheerikhaskash, *Pers.;* Ufeem, *Hindost.*

Opium is generally believed to be derived exclusively from *Papaver somniferum;* though every species of poppy is capable of yielding it to a greater or less extent, and some authors assert that *Papaver orientale* is its real source. The United States, British, and French Pharmacopœias recognize only the first-mentioned species.

Papaver somniferum. L. *Sp. Pl.* (1753) 508; Willd. *Sp. Plant.* ii. 1147; *B. & T.* 18. There are several varieties of this species, of which the two most prominent are distinguished by the titles of the white and the black poppy, derived from the color of their seeds. It is the former (var. *Album* D. C.) which is usually described as the proper opium plant. The *white poppy* is annual, with a roundish, smooth, erect, glaucous, often branching stem, usually rising two or three feet in height, but sometimes five or even six feet in favorable situations. The leaves are large, variously lobed and toothed, and alternately disposed on the stem, which they closely embrace. The flowers are terminal, very large, and of a white or silver-gray color. In India they appear in February, in Europe and the United States not earlier than June, July, or August. The calyx is smooth and composed of two leaves, which fall when the petals expand. These are usually four in number; but there is a variety in which the flower is double. The ovary is smooth and globular, supports a radiated stigma, and is surrounded by numerous short and slender filaments, with erect, oblong, compressed anthers. The capsule is smooth and glaucous, rounded, from two to four inches in diameter, somewhat flattened at the top and bottom, and crowned with the persistent stigma, the diverging segments of which are arranged in a circle upon the summit. It contains numerous minute white seeds, which when perfectly ripe escape through small openings beneath the stigma. In the *black poppy*, the flower, though sometimes white, is usually violet-colored or red, the capsule somewhat smaller and more globular, and the seeds of a brown or blackish color.

All parts of the poppy contain a white, opaque, narcotic juice; but the leaves, analyzed by M. Blondeau, yielded none of the active principles by which opium is characterized. (*Journ. de Pharm.*, vii. 214.) It is in the capsule that the juice most abounds and the virtues of the plant chiefly reside. Hence this part is sometimes employed medicinally. (See *Papaver.*) The seeds are destitute of narcotic properties, and are even used as food. The Romans employed them in the preparation of various dainties. They abound with a bland oil, called commercially *poppy-seed oil*, which may be extracted by expression. It is of a straw-yellow color, without odor, and of a pleasant almond taste. It is without narcotic properties, and much resembles olive oil, as a substitute for which and an adulterant of which it is very largely used on the continent of Europe. It has a low congealing point, thickening only at —15° C. (5° F.) and solidifying at —20° C. (—4° F.). The black variety is specially used for the expression of oil, as its culture is easier, and the oil-percentage in both varieties is practically the same, ranging between 50 and 60 per cent. As the oil-cake generally retains about 8 per cent. of the oil, the yield by expression is from 42 to 50 per cent. Poppy oil contains the glycerides of stearic and palmitic acids, together with those of linolic, linolenic, and oleic acids. Of the liquid fatty acids, linolic constitutes 65 per cent., oleic 30 per cent., and linolenic 5 per cent. Myristic and lauric acids seem to be absent. The oil is an article of much importance on the con-

tinent of Europe, particularly in France and Germany, where it is employed for culinary and pharmaceutic purposes, in painting and the manufacture of soap, and in other ways, as a substitute for olive oil. The poppy does not appear to elaborate the milky fluid in which its narcotic properties reside before a certain period of its growth; for we are told that, in Persia, the young plants which are pulled up to prevent too thick a crop are used as potherbs; and the *μήκων* of the Greeks, which is believed to be identical with the *Papaver somniferum*, is said by Hippocrates to have been nutritive.

Though generally believed to be a native of Asia, this species of poppy grows wild in the south of Europe, and even in England,* whither its seeds are supposed to have been brought at a very early period. It was cultivated by the ancient Greeks, and is mentioned by Homer as a garden-plant. It is at present cultivated very extensively in India, Persia, Egypt, and Asiatic Turkey, for opium; and in several parts of Europe, especially in the northern departments of France, and in the south of Germany, mainly for the seeds; though in both countries good opium is at the same time produced. It is said that in some parts of China,† especially in the province of Se-Chuan, notwithstanding that the drug is so abundantly imported from India, great quantities of it are produced for the supply of the masses of the people, the Bengal opium being used only by the rich. (*Neues Repertorium*, xii. 80, 1863.) In this country it was until recently found only in our gardens as an ornamental flower; but of late attempts have been made to cultivate it in the United States.‡ The opinion that a hot climate is not necessary for the production of the narcotic principles has the support of Guibourt (*Journ. de Pharm.*, Sept. 1867, p. 222), and would seem to be established by the facts that the opium of Anatolia is richer in morphine than that of the much hotter regions of Bengal and Upper Egypt, and that, while the best Smyrna opium seldom yields more than 12 per cent. of the alkaloid, that produced in the north of France yields from 20 to 24 per cent. (M. Bussy, *Ibid.*, p. 221.) Australian opium of very good quality is said to come into Melbourne from the Bacchus Marsh district, in the form of balls. (*Austral. Journ. Pharm.*, Nov. 1887.)

The process for procuring opium from the poppy, as practised by the modern inhabitants of India and Persia, according to the reports of Kerr and Kaempfer, is very nearly the same as that described by Dioscorides as employed in his own times, about eighteen hundred years ago; and the accounts of Bélon, Olivier, Texier, and more recently M. Bourlier, as to the mode of collection in Asia Minor, are not materially different. As the capsules abound most in the narcotic juice, it is from these that the opium is procured. According to Texier, a few days after the fall of the flower, men and women proceed to the fields, and make horizontal incisions into the capsule, taking care not to penetrate its cavity. A white juice exudes, and appears in the form of tears upon the edges of the incisions. The field is left in this state for twenty-four hours, after which the juice is scraped off by means of large blunt knives. A portion of the epidermis of the capsule is also removed, and constitutes about one-twelfth of the whole product. Each poppy-head affords opium but once. Thus collected, the opium is in the state of an adhesive and granular jelly. It is placed in smaller vessels, where it is beaten, and at the same time moistened with saliva. Another method of extracting the virtues of the capsules is to select such as have ceased to yield their juice by exudation, to beat them with a small proportion of water, and to inspissate the liquid thus obtained by artificial heat. The ancient Greeks were acquainted with both processes, as appears from the writings of Dioscorides. The term *ὀπίον*, derived from *ὀπός*, *juice*, they applied to the substance procured by incisions, which answers precisely to the modern opium. The inspissated expressed juice they called *μηκώνιον*, from *μήκων*, the name of the plant. Tournefort states that the latter preparation is exported from Turkey as opium, the former being much more valuable, and there-

* Various attempts have been made in England to cultivate the poppy, all of which have resulted in commercial failure. (For particulars, see previous edition U. S. D.; also *Edinb. Phil. Journ.*, i. 258.) The same may be said of the attempts to cultivate opium in France, which have apparently ceased since the death of M. Aubergier, who devoted much time and money to the subject. (For particulars, see 15th ed. U. S. D.; also *P. J. Tr.*, xv. 693.)

† In spite of the prohibitions of the Imperial government, the production of opium is said to be greatly on the increase in China, the cultivation of the poppy paying much better than that of wheat. (*P. J. Tr.*, ix. 1878.)

‡ In 1865, Mr. P. Robertson, of Campbell Co., Virginia, produced opium which yielded to the analysis of Mr. I. J. Grahame 4 per cent. of morphine, besides narcotine. (*A. J. P.*, 1867, p. 50.) Dr. H. Black, of Bolivar, Tennessee, produced an opium from which Mr. E. S. Wayne obtained 10·2 per cent. of morphine. (*Ibid.*, Jan. 1868.) In 1868 considerable interest was aroused by the statements of Mr. W. C. Wilson, which were, however, proved by Prof. Procter to be incorrect. (See 14th and 15th eds. U. S. D.) Very fine opium has been produced by Mr. J. H. Flint, of California (*A. J. P.*, 1874, p. 105); also in Minnesota, by Mr. E. Weschke (*Contributions Dep. Pharm. University of Wisconsin*, 1886); but in the opinion both of Mr. Flint and of Mr. Weschke the high price of labor forbids the profitable production of opium in the United States. For an account of North Carolina opium, see *Proc. A. P. A.*, 1894, 286; also *A. J. P.*, 1896, 435.

fore retained in the country for the use of the great and wealthy,—an error which at one time received wide credence.*

Commercial History. Commerce is supplied with opium chiefly from Hindostan, Persia, Egypt, and Asiatic Turkey.† Immense quantities are produced in the Indian provinces of Bahar and Benares, and in the more interior province of Malwa. The opium of Hindostan is distributed extensively through continental and insular India, where it is habitually employed in the place of spirituous liquors. Great quantities are also sent to China, into which it finds an easy entrance, notwithstanding prohibitory laws.‡ Much was formerly imported by the East India Company into England, through which a small proportion reached our own country. For various reasons India opium no longer enters Western commerce to any extent. It is produced in Hindostan chiefly under government supervision. The drug as first obtained is semi-liquid, owing to the excessive dews, but is allowed to drain and dry by spontaneous evaporation until only 30 per cent. of moisture is left, when it is taken to the government factories. Great care is exercised to prevent adulteration. In the factories it is worked up with the drainings (known as *passēwā*), poppy petals, and ground poppy plant into balls of standard strength. These are called "*cakes*," are about six inches in diameter, and are prevented from adhering by being rolled in the ground poppy plant. *Malwa* opium is a variety not made in Hindostan proper nor under government supervision. Its quality varies greatly. Of the opium produced in Persia, very little is brought to this country; and it is scarcely known in our market as a distinct variety. Much was formerly produced in Upper Egypt, especially in the district of ancient Thebes, which was supposed to yield it in greatest perfection. Hence it was long known by the name of *Opium Thebaicum*, and laudanum is still sometimes directed in prescriptions as *Tinctura Thebaica*. Its cultivation has been again introduced into Egypt, and considerable quantities are exported.

Turkey opium is produced in Anatolia, and shipped chiefly from the port of Smyrna. It is brought to the United States either directly from the Levant or indirectly through different European ports. The amount of opium imported in 1897 was 1,072,914 lbs., valued at $2,184,727; at the same time there were imported 157,061 lbs. of prepared opium for smoking, valued at $1,132,861. Turkey opium usually comes to us in masses of irregular size and shape, generally more or less flattened, covered with leaves or the remains of leaves, and with the reddish capsules of some species of *Rumex*, which are said to be absent in the inferior kinds, and may therefore be considered as affording some indication of the purity of the drug. We may account for this circumstance upon the very probable supposition that these capsules are removed during the operation which the masses undergo in the hands of the merchants after leaving those of the cultivators. We are told by the French writers that extensive frauds are practised at Marseilles in this branch of commerce. The opium taken thither from the Levant is first softened, and then adulterated with various matters which are incorporated in its substance. To use a strong expression of Guibourt, they make the opium over again at Marseilles. Our traders to the Mediterranean would do well to bear this assertion in mind. According to Dr. A. T. Thomson, one-fourth part of Turkey opium generally consists of impurities. Sand, ashes, the seeds of different plants, extracts of the poppy, *Lactuca virosa*, *Glycyrrhiza glabra*, and *Chelidonium glaucum*, gum arabic, tragacanth, salep, aloes, even small stones and minute pieces of lead and iron, are mentioned among the substances employed in the sophistication of the drug. Tschirch (*A. J. P.*, 1898, 488) proposes the use of the Roentgen ray in detecting such adulterations. Mr. Landerer, of Athens, was informed by a person who had been engaged in the extraction of opium, that grapes, freed from their seeds and crushed, were almost universally mixed with

* For an elaborate, recent detailed account of methods of opium production in India, see *P. J. Tr.*, vol. xx. 178.

† For information in regard to the methods of culture in Turkey and Asia Minor, see *Journ. de Pharm.*, 3e sér., xiii. 105; *P. J. Tr.*, March, 1854; *A. J. P.*, 1863, 362; also 14th edition *U. S. D.*

‡ The India-Chinese opium trade, which has given rise to so many wars and controversies, is, according to the English consul at Shanghai, "likely to disappear by a sort of painless extinction," the importation from India into China having fallen from nearly ten millions of pounds annually to less than seven millions. This change is not the result of any lessening in the use of opium as an intoxicant by the Chinese, but to the increase of poppy cultivation throughout the Celestial empire. As much as 1,300,000 pounds of Chinese opium were in 1895 received in the Shanghai market from Western China alone. The cost of the native drug to the consumer is said to be exactly half that of the India opium. The importance of this matter is shown by the fact that in the season of 1894–95, 537,556 acres of land were under poppy cultivation in British India. The comparatively low price of the Chinese opium seems not to depend upon differences in quality. The percentage of morphine does not decide the value of smoking opium, certain opiums being preferred by the Chinese, although they contain a very small percentage of morphine. On examination of the Chinese opium, Mr. Frank Brown found it remarkably free from foreign materials. The percentage of morphine varies from $4\frac{3}{10}$ in the Kwei-chu opium to $11\frac{3}{10}$ in the Szechuen opium. For further details, see *P. J. Tr.*, lv. and lvii.

the poppy juice, and that another adulteration consisted of the epidermis of the capsules and stem of the plant, pounded in a mortar with the white of egg. (*A. J. P.*, xv. 238.) According to Mr. Wilkins, who witnessed the collection of opium, the inspissated juice of the grape, thickened with flour, is often used for the same purpose. (*P. J. Tr.*, xiv. 400.) In England a sophisticated opium was some years since prepared, which, though so nearly resembling good Turkey opium in appearance that by the eye alone it was difficult to detect the fraud, was yet wholly destitute of the active principle of the drug. Portions of it were sent into the markets both of France and of this country. A sample of a similar drug, perhaps the same, was examined by Prof. Aiken, examiner of drugs for the port of Baltimore, and found to contain but 1·10 per cent. of morphine. (See *A. J. P.*, July, 1859, p. 374.) It was probably the genuine drug, deprived of its morphine by some process which did not materially disturb the visible arrangement of its particles.* (*Ibid.*, x. 261.)

* The great importance of opium renders it desirable that all its commercial varieties should be accurately described, and their relative value, so far as possible, ascertained. The varieties of this drug may be discussed according to the countries in which they are produced, an arrangement which we here adopt.

I. TURKEY OPIUM. This title belongs to the opium produced in the Turkish province of Anatolia, and exported from Smyrna and Constantinople. According to some authorities, there is no essential difference between the parcels of the drug brought from these two ports. Others maintain that they are distinct varieties, differing in their interior structure, and probably also in the precise place of their production and the mode of their collection. The truth probably is that most of the opium shipped at Constantinople is produced in the more northern parts of the opium districts of Anatolia, while that from Smyrna is collected in the provinces more convenient to the latter city; and, though it is possible that an identical drug may often be brought from the two ports, yet there are grounds for arranging it under different varieties, as derived from these different sources. There can be little doubt also that a portion of opium which is taken to Constantinople is produced in Macedonia in Europe, which must, therefore, be added to the opium-producing regions. (*Neues Repert.*, xvi. 751, 1867.)

1. *Smyrna Opium.* This is the variety which is, beyond all comparison, most abundant in our markets; and it is from this that the ordinary descriptions of opium are drawn up. It comes to us in masses of various size, usually from half a pound or somewhat less to a pound in weight, sometimes, though rarely, as much as two or even three pounds, originally, perhaps, of a globular form, but variously indented, and rendered quite irregular in shape by the pressure to which they have been subjected, while yet soft, in the cases which contain them. Sometimes they are even pressed out into flat cakes. As brought into market, the lumps are usually hard on the outside, but still soft within. They are covered externally with the remains of leaves, and with the reddish capsules of a species of Rumex, which have no doubt been applied in order to prevent the surfaces from adhering. Notwithstanding, however, this coating, the masses sometimes stick together, and two or more become consolidated into one. In this way the fact may be accounted for, that the seeds of the Rumex are occasionally found in the interior of the masses. In the finer parcels of Smyrna opium the color internally is light brown; in the inferior it is darker. A peculiar character of this variety is that, when a lump of it is cut into and then carefully torn, numerous minute shining tears are observable, particularly under a microscope, bearing some resemblance to small seeds, but readily distinguishable by pressure between the fingers. They are undoubtedly formed from the drops of juice which escape from the incisions in the capsules, and which, according to Bélon, are allowed to concrete before they are removed. From the account of the same author it appears that after the juice has been collected it is not subjected to the process of kneading or beating, as in the case of other varieties of the opium; so that the tears preserve their original shape in the mass. It is probably owing to the peculiar mode of collecting Smyrna opium, that minute pieces of the skin of the poppy capsules are found intermingled in the mass, these being separated in the process of removing the adhering tears. In the best specimens of Smyrna opium, these fragments of the capsules are the only impurities. This variety of the drug is of very different qualities, the finest kinds yielding, according to Merck, as much as 13 per cent. of pure morphine, while from some very bad parcels he could not procure more than 3 or 4 per cent. In these inferior specimens the color is darker, the smell is often musty, and there is very generally more or less mouldiness both upon the surface and in the interior of the masses, indicating perhaps too much moisture in the opium originally, or its subsequent exposure to an injurious degree of dampness. Good Smyrna opium ought to yield 10 or 11 per cent. of morphine. Dr. Christison, however, states that he has not been able to procure more than 9 per cent. from the finest Smyrna opium. According to Landerer, little of the opium is produced in the immediate neighborhood of Smyrna, the greater portion being brought, on the backs of camels, from a distance of from ten to eighteen days' journey. (*Journ. de Pharm.*, 3e sér., xxiii. 33.) The same writer states that the opium is chiefly prepared at Kara-Hissar, near Magnesia. The incisions are generally made before sunrise. The juice is partly caught in mussel-shells, and dried in the sun. This is considered the best. Every evening the juice which has dried upon the capsules is scraped off, with a portion of the epidermis. The poppy is then cut down, and stripped of its leaves, which are boiled in water, and the liquor is evaporated to the consistence of an extract. With this the inspissated juice is incorporated, and the mixture is then formed into cakes, wrapped in poppy leaves, and placed on shelves to dry. (See *A. J. P.*, xxiii. 251.) It is very evident, from the interior structure of the *best Smyrna opium*, that it has not been prepared in the way described by Landerer; though his account is probably true in reference to inferior varieties.

2. *Constantinople Opium.* Most of the Constantinople opium is in lumps from half a pound to two and a half pounds in weight, and scarcely distinguishable in exterior appearance from those of the former variety, being equally irregular in shape, and in like manner covered with the capsules of the Rumex. According to Merck, however, it often differs strikingly from the Smyrna opium in its interior constitution, being wholly destitute of the tears which characterize that variety. This would indicate some difference in the mode of collecting and preparing the juice. In the case of the Constantinople opium it is probably removed from the capsules before concretion. Merck says that he has not discovered in this variety those minute portions of the poppy capsules which are usually present in Smyrna opium. The average quality of the Constantinople opium, as above described, is about equal to that of the drug from Smyrna; but it appears to be occasionally purer, as Merck obtained from one specimen as much as 15 per cent. of pure morphine. Dr. R. Bauer, of Constantinople, who for many years had the opportunity of becoming familiar with the varieties of opium which reach that city, in 1867 denied that any of the varieties produced near Smyrna contain tears, except the single one from Magnesia. (*Neues Repert.*, xvi. 751.)

The adulteration of opium has given rise to much complaint on the part of pharmacists, and various plans of customs legislation have been suggested by which it has been thought that these adulterations could be prevented. It is, however, obviously impossible to pronouncedly

In an account, by M. Bourlier, of the culture of the poppy and collection of opium in Bithynia, a province of Asia Minor, near Constantinople, it is stated that the lumps, when formed out of the concrete juice, are enveloped in poppy leaves; and no mention is made of the use of the Rumex capsules to prevent adhesion. It is the opium here collected which, according to M. Bourlier, is known throughout the Levant and in Europe as Constantinople opium. The same authority states that the yolk of egg is sometimes largely used for adulterating opium,—a fraud which may be detected by the large proportion of fatty matter which the adulterated drug yields to ether, and by the impossibility of drying it so as to fit it for pulverization. (*Annuaire de Thérap.*, 1859, p. 4.)

Guibourt describes another variety of Constantinople opium of much inferior character. "It comes," he observes, "in small, flattened cakes, sufficiently regular and of a lenticular shape, from two to two and a half inches in diameter, and always covered with a poppy leaf, the midrib of which divides the surface into two equal parts. It has an odor similar to that of the preceding variety, but feebler, and it blackens and dries in the air. It is more mucilaginous than Smyrna opium, and contains only half as much morphine." These characters are obviously those of Egyptian opium; and, though the parcels which came under the notice of Guibourt may have been imported directly from Constantinople, it is highly probable that they were originally from Alexandria. Mr. Stettner, of Trieste, though well acquainted with the opium commerce of that port, admits no such Constantinople opium as that described by Guibourt. (*Annal. der Pharm.*, xxiv. 65.) According, however, to Dr. Bauer, the opium collected in the districts nearest Constantinople is mostly in small pieces, often of only two or three ounces, which are always invested with poppy leaves, or more rarely with grape leaves, generally smooth, and without Rumex capsules; and this description corresponds with Guibourt's. (*Neues Repert.*, xvi. 754, 1867.)

A number of varieties of opium produced in European and Asiatic Turkey circulate more or less in Austria and other parts of Germany, which have been described by Dr. C. Finckh in *Buchner's Repertory* (vol. xvi. p. 749), and of which we propose to give a brief account here:

Opium of Géwé or *Géré* is gathered from a poppy with red flowers, and comes in the form of small rounded cakes, weighing 2 or 3 ounces, enveloped in the leaves of the poppy, with a smooth and shining surface, which seems to be divided into two halves by the median nerve of the leaf. The interior is in layers of light- and deep-colored opium; and its yield of morphine is from 12 to 15 per cent.

Opium of Amasia differs from the preceding only in this, that there are two enveloping poppy leaves, placed crosswise, and with their lower surface outward, so as to give a rugose appearance to the cakes. In the interior the mass is homogeneous, but is very analogous to the *Géwé* opium.

Opium of Malatia is in small loaves, round or somewhat oval, from 4 to 5 ounces in weight, made with the greatest care, and enveloped in poppy leaves, with a rugose surface, and the median line corresponding to the middle of the loaves. The borders of these, frequently deprived of the leaf, are very delicate. The substance of the loaf is homogeneous, but generally poor in morphine.

Opium of Magnesia is in irregular cakes or loaves, from 1 to 4 ounces in weight. They are covered first with a layer of Rumex seeds, and afterwards with poppy and vine leaves, and owe their irregular form to the envelopes, for originally they are rounded. The interior is composed of agglutinated tears, and is of excellent quality.

Opium of Salonica, or of *Kutchina*, has a strong analogy in all respects with that of Géwé, for which it is often substituted. (See analysis by Dr. A. R. L. Dohme, *Proc. A. P. A.*, 1893.)

The following represent the varieties in which Smyrna opium appears in the market:

The *Opium of Balukhissar*, which is the chief source of the Smyrna opium, is in cakes of from 4 to 12 ounces, irregular, though originally globular-ovoid. They are covered with Rumex seeds, and present, besides, on their surface poppy leaves irregularly applied. The mass is formed of tears lighter or deeper colored, and is so rich in morphine as to cause this variety to be always sought for in the market. (See recent analysis by Dr. A. R. L. Dohme, *Proc. A. P. A.*, 1893.)

The *Opium of Cataya* is generally in lumps half as large as the preceding, which it approaches closely in its characters and in its yield of the alkaloid.

The *Opium of Taushan* or *Taushanly* is in irregular lumps, twice as long as broad, and weighing from 3 to 5 ounces. The mass consists of tears, and is carelessly enveloped with the poppy leaf and a few Rumex seeds. This variety is rich in morphine.

The *Opium of Angora* or *Engiri* is readily known by its under surface being covered with only one leaf of the poppy. The masses, being almost spherical, appear to have been originally in balls. Their weight is from 6 to 8 ounces, the interior homogeneous, and the quality inferior.

The *Opium of Kara-Hissar* is in balls, flattened beneath, of the weight of 6 or 8 ounces, and covered with poppy leaves and Rumex seed. Though carefully prepared, this variety formerly, from its deficiency in morphine, was of inferior quality; but it has improved of late years. (See recent analysis by Dr. A. R. L. Dohme, *Proc. A. P. A.*, 1893.)

The *Opium of Cigusti* is in irregular loaves, 6 or 8 ounces in weight, enveloped in poppy leaves and Rumex seed. Though rarely falsified, it often contains fragments of the poppy capsules, and forms a mass sometimes of distinct tears, sometimes not. Occasionally rich, it is almost always mixed with the various forms of Smyrna opium.

Dr. Finckh has noticed the following adulterations: opium of Macedonia, with clay; of Angora, with wax; of Amasia, with gum; of Taushan, with liquorice; of Balukhissar, with melted pitch. He has even found an opium evidently made almost entirely of clay and cow-dung. The opiums of Macedonia are most frequently adulterated. (*Journ de Pharm.*, Nov. 1869, 377.)

Bulgarian Opium has been met with in European commerce. (*Chem. and Drug.*, 1893, 733.)

II. EGYPTIAN OPIUM. This is in flat roundish cakes, of various dimensions, sometimes as much as six inches in diameter and a pound in weight, usually, however, much smaller, and sometimes not weighing more than half an ounce. These cakes are either wrapped in a poppy leaf, so placed that the midrib divides the surface into two equal parts, or exhibit vestiges of such a covering. Occasionally the brown color of the opium is seen through the leaf, and the surface appears as if uncovered, while the leaf is still present. This variety of opium is always destitute of the Rumex capsules, and differs from the Smyrna opium also in being brittle instead of tenacious, and as hard in the centre as at the surface of the mass. Its fracture is conchoidal and of a waxy lustre, and small fragments of it are translucent. Its color is usually redder than that of Smyrna opium, though sometimes dark. Some of the pieces, on exposure to the air, become damp and sticky on the surface, indicating the fraudulent addition of a deli-

affect the action of the semi-barbarians who are engaged in the cultivation of opium by any American legislation. Usually the substances which are used to adulterate the drug are inert, and therefore do no harm except by weakening its activity. The U. S. Custom-House requires

quescent substance. The odor is similar to that of Smyrna opium, but weaker. It is an inferior variety, as the best of it, examined by Merck, yielded only 6 or 7 per cent. of morphine, and a specimen of it was found by Mr. J. Evans, of Philadelphia, to contain not more than 3·55 per cent. Egyptian opium, therefore, should never be dispensed by the apothecary, or employed in the preparation of his tinctures, as the prescription of the physician is based upon the strength of good Smyrna opium, which is about twice that of the Egyptian. That the deficiency of morphine in Egyptian opium is not climatic would seem to be proved by the fact that M. Gastinel has produced opium in his garden at Cairo containing 12 per cent. of morphine. (*Journ. de Pharm. et de Chim.*, 4e sér., iv. 415, 1866.)

III. INDIA OPIUM. Little if any of this opium reaches our market. There appear to be two chief varieties of it,—one produced in Bahar and Benares, in the Bengal Presidency, and called *Bengal opium*, the other in the interior provinces, and designated by the name of *Malwa opium*. For minute description of Indian opium, see *P. J. Tr.*, xi., xii., abstracted *A. J. P.*, xxiv. 118; also *Pharmacographia*.

1. *Bengal Opium, Benares Opium, Patna Opium.* It is in round balls, weighing three pounds and a half, invested by a coating half an inch thick, composed of agglutinated leaves and poppy petals. The interior of the mass is of a brownish-black color, of the consistence of a stiff paste, and possessed in a high degree of the characteristic odor and taste of opium. The analyses of India opium vary decidedly in their results: Eatwell, 2·17 to 3·67 per cent. of morphine, 3·85 to 5·70 per cent. of narcotine; Procter (Patna opium), morphine, 5 per cent.; Flückiger and Hanbury (Khandesh opium), morphine, 6·07 per cent., (Patna opium) morphine, 8·6 per cent., narcotine, 4 per cent.; Solly (Khandesh opium), morphine, 7 per cent.; Watson (a number of varieties), 3·5 to 6·1 per cent. of morphine. (*P. J. Tr.*, xi. 362; *A. J. P.*, xxi. 194; *Pharmacographia*, 2d ed., p. 61.) India opium is, therefore, much inferior to the best Smyrna opium in its yield of morphine, while it is richer in narcotine. Its inferior character is possibly, in some degree, owing to the circumstance that the juice, after collection, is kept for some time before it is made up, and consequently undergoes fermentation. (See *P. J. Tr.*, 1895, 208; *Pharm. Central.*, 1895, 589; also *Chem. and Drug.*, 1896, 134.)

Garden Patna Opium is prepared in Bahar with peculiar care, from juice which has not been suffered to undergo fermentation. It is in cakes three or four inches square, and about half an inch thick, which are packed in cases with a layer of mica between them. These cakes are without covering, hard, dry, and brittle, of a uniform shining fracture, and not unlike an extract in appearance. The color is sometimes almost black, and sometimes of a light brown, not unlike that of Egyptian opium. Dr. Christison states that it is much superior to the globular Bengal opium, and that some specimens are little inferior to Turkey opium in the proportion of morphine.

2. *Malwa Opium.* This sometimes occurs in flat, roundish cakes, five or six inches in diameter, and from four to eight ounces in weight. In other instances it is in rectangular masses called bricks, or even in roundish balls. It seems never to be encased in poppy remnants. They are commonly quite hard, dry, and brittle, of a light-brown color, a shining fracture, a compact homogeneous texture, and free from mechanical impurities. The quality is very variable. A specimen of Malwa opium described by Dr. Carson (*A. J. P.*, xxi. 195) broke with a rough fracture, which was of a blackish-brown color, here and there showing irregular oily spots. Prof. Procter obtained from it 9¼ per cent. of morphine.

IV. PERSIAN OPIUM. The cultivation of opium greatly increased in Persia a few years ago, the crop of 1880 having been estimated at about 1,200,000 lbs.; consequently, whilst formerly it was a rare variety, since 1870 it has been sent in increasing quantities into European commerce, and comes to some extent to this country; but, according to the reports of Consul-General Benjamin (*P. J. Tr.*, Nov. 1884), there has been a decline in the production of opium in Persia, owing partly to the large adulterations which have been practised, and partly to the disfavor of the government. It still continues to be, however, one of the principal sources of wealth to the government. (*P. J. Tr.*, 1887, p. 904.) It is in different forms. Sometimes it is in cylindrical pieces, about three and a half inches long and half an inch thick, wrapped in glossy paper, tied with a cotton thread, and each weighing about half an ounce; more frequently it is in short rounded cones weighing from 6 to 10 ounces; it also occurs in flat circular cakes. It is of a uniform consistence, but exhibits, nevertheless, under the microscope, small agglutinated tears, much less than those of Smyrna opium. It has the liver-brown color of Egyptian opium, a virose musty odor, and a very bitter taste, and, like Egyptian opium, softens in a moist atmosphere. The character of the opium has undoubtedly changed of late years, and it is said that the Persians now produce two distinct forms,—one pure, destined for the Western market, and one adulterated and oiled, for the China trade.

In 1860 Persian opium was described by Dr. Reveil as being in three forms in Paris. *One* was in spherical cakes, without envelope or Rumex capsules. In physical characters it closely resembled the cylindrical variety, though softer and more hygrometric. It had a strongly virose odor, and a bitter slightly sweetish taste. The *second* was in irregular masses, liver-colored, of a virose smell and bitter taste, brittle, smooth and shining, compact, and very hygrometric. The *third* was in the form of flat cakes, covered with an unknown leaf with some Rumex capsules, of a reddish-brown color, tasting and smelling like the preceding, compact, and smooth. Of these the first and third contained, each, 31·6 per cent. of glucose; the second, 13·9 per cent. All these varieties were remarkable for the absence of obvious impurities, such as are insoluble in water and alcohol. From 75·2 to 84·2 per cent. was soluble in water, from 71·6 to 81·6 in alcohol at 85°. The *cylindrical* variety yielded 8·15 per cent. of morphine; the *spherical*, 6·4 per cent.; the *irregular*, 7·1 per cent.; and the *flat and coated*, 5·1 per cent. The presence of glucose in such large proportions may be explained by the asserted fact that honey is sometimes mixed with opium at the time of its collection. Though the proportion of morphine is considerable in these varieties, yet, in consequence of their large proportion of soluble matter, they yield comparatively feeble extracts. (*Journ. de Pharm.*, Août, 1860, p. 101.) Subsequently to M. Reveil's investigation, two samples of Persian opium were examined by M. Séput, of Paris, one of which yielded 9·33 and the other 9·37 per cent. of morphine. (*Ibid.*, Mars, 1861, p. 163.)

Analyses made in 1873 showed a great improvement in Persian opium. Consul-General Ross stated that, as prepared for the European market, it averaged 12 per cent. of morphine. (*P. J. Tr.*, May, 1873, p. 883; June, 1880, p. 1002.) Messrs. Rosengarten, the well-known manufacturing chemists, of Philadelphia, inform us that they have used large quantities of the Persian opium, and obtained from it an average of 10 per cent. of morphine. Mr. W. D. Howard examined a sample of fine Persian opium sent to England as "perfectly pure," which yielded to him on analysis, without previous drying—morphine, crystallized from alcohol, 10·40 per cent.; codeine, anhydrous, 0·29 per cent.; narcotine, 2·50 per cent.; thebaine, 0·57 per cent.; cryptopine, 0·09 per cent.; papaverine, a trace. He is

that opium, in order to enter the United States at all, shall conform to the U. S. P. standard and contain not less than 9 per cent. of morphine. It would perhaps be better if this percentage should be raised to 10 per cent., though it is a question whether shutting out the weakened and cheaper grades of opium does not injure the manufacture of morphine in the United States, and probably the present tariff legislation is sufficient.

Opium is regarded as inferior when it has a blackish color, a weak or empyreumatic smell, a sweet or slightly nauseous and bitter taste, a soft, viscid, or greasy consistence, a dull fracture, or an irregular, heterogeneous texture, from the intermixture of foreign substances. It should not impart a deep-brown color to the saliva, nor leave a dark uniform trace when drawn over paper, nor form with water a thick viscid solution.

Properties. Good opium has a peculiar, strong, narcotic odor, and a bitter, somewhat acrid taste. It is officially described as "in irregular or subglobular cakes, with the remnants of poppy leaves and fruits of a species of Rumex adhering to the surface; plastic, or of a harder consistence; chestnut-brown or darker, and somewhat shining; internally showing some tears and fragments of vegetable tissue. It has a sharp, narcotic odor, and a peculiar, bitter taste." *U. S.* When long chewed it excites much irritation in the lips and tongue, and may even blister the mouths of those unaccustomed to its use. Its color is reddish brown or deep fawn; its texture compact; its sp. gr. 1·336. When drawn over paper it usually leaves an interrupted trace of a light-brown color. It is often soft in the interior of the mass, and in this state is tenacious; but when exposed to the air it gradually hardens, and ultimately becomes brittle, breaking with a shining fracture, and affording, when pulverized, a yellowish-brown powder, which becomes adhesive upon a slight elevation of temperature. It readily inflames upon the application of a lighted taper. It yields its virtues to water, alcohol, and diluted acids, but not to ether. To all these menstrua it imparts a deep-brown color. Alcohol dissolves about four-fifths of it. Pelletier states that the proportion taken up by water varies in all specimens. He never found the quantity of extract prepared with cold water to exceed 12 parts out of 16. (*Journ. de Pharm.*, Nov. 1832.)

Chemical Constituents. Much attention has been devoted to the chemical constitution of opium. It was through the researches into the nature of this substance that chemists were led to the discovery of the alkaloids, which are usually the active principles of the plants in which they are found, and have attracted much notice, and been applied so advantageously to the treatment of disease. To Sertürner, an apothecary at Eimbeck, in Germany, belongs the credit of having opened this new and most important field of research. In the year 1803 M.

unable to say whether it contained any narceine. It was of a light brown color, and had been collected without the excessive use of oil. (*P. J. Tr.*, March 11, 1876.) For an account of the opium made at Yezd, see *Amer. Drug*, 1894, 428.

V. MOZAMBIQUE OPIUM. The poppy culture has been introduced into Mozambique for the production of opium for the Chinese market. A specimen of the product is said to have yielded 4 per cent. of morphine, 4·3 per cent. of narcotine, and 40 per cent. of moisture. (*P. J. Tr.*, x. 63.)

VI. CHINESE OPIUM probably never reaches the European market. It is imported to some extent into the United States through San Francisco, but appears not to find its way into the ordinary channels of trade, and is probably used exclusively by resident Chinese for smoking purposes. The U. S. duty upon opium is one dollar a pound, but the custom-house authorities view the Chinese variety as an extract, and levy six dollars a pound; hence, probably, the ever-recurring attempts at its smuggling. It occurs in flat, oval cakes, wrapped first in white tissue, then in thin brown, paper, labelled in Chinese characters with the name of the province and the seller. The color varies from dark brown to black; the fracture is sometimes granular, sometimes smooth; the odor usually strongly narcotic. (*Chem. and Drug.*, 1895, 855.)

"BOSTON OPIUM," so called, was a sophisticated article, skilfully adulterated so as to reduce the percentage of morphine to the lowest point compatible with getting through the United States Custom-House and yet to get the physical appearance of a high-grade opium.

The following exhibits the results obtained by Guibourt in the analysis of various opiums. (*Journ. de Pharm.*, Janv., Fév. et Mars, 1862.)

		Soft.	Hard.	Dried.

Derosne made known the existence of a crystallizable substance which he had discovered in opium, and which he erroneously believed to be the active principle. In the following year, Seguin discovered another crystallizable body, which experience has proved to be the true narcotic principle of opium; but he did not fully investigate its nature, and no immediate practical advantage accrued from his excellent analysis. About the same time, Sertürner was engaged in a similar investigation, the results of which, very analogous to those obtained by Seguin, were published in a German journal, without, however, attracting general attention. In this state the subject remained till 1817, when Sertürner announced the existence of a saline compound in opium, consisting of a peculiar alkaline principle united with a peculiar acid, and clearly demonstrated the precise nature of a substance which, though before discovered both by Seguin and himself, had been hitherto but vaguely known. To the alkaloid, in which he correctly conceived the narcotic powers of opium to reside, he gave the name of *morphium*, which has been since changed to *morphine*, in order to render it conformable with the titles of the other alkaloids. The acid he called *meconic*, a term derived from the Greek name of the poppy. The correctness of the statements of Sertürner was confirmed by Robiquet, who also satisfactorily demonstrated that the substance obtained by Derosne and called by him the *salt of opium* was a principle altogether distinct from morphine, though supposed to possess considerable influence over the system. In the belief in its narcotic powers, Robiquet denominated it *narcotine*, a title which it still retains. A number of other alkaloids have since been discovered in opium, although most of these are in very limited amount, and the existence of some is not quite definitely established. According to the views of its constitution at present accepted, it contains: 1. *Morphine*, $C_{17}H_{19}NO_3$; 2. *Codeine*, $C_{18}H_{21}NO_3$; 3. *Thebaine*, $C_{19}H_{21}NO_3$; 4. *Papaverine*, $C_{20}H_{21}NO_4$; 5. *Meconidine*, $C_{21}H_{23}NO_4$; 6. *Codamine*, $C_{20}H_{25}NO_4$; 7. *Laudanine*, $C_{20}H_{25}NO_4$; 8. *Laudanosine*, $C_{21}H_{27}NO_4$; 9. *Lanthopine*, $C_{23}H_{25}NO_4$; 10. *Protopine*, $C_{20}H_{19}NO_5$; 11. *Cryptopine*, $C_{21}H_{23}NO_5$; 12. *Rhœadine*, $C_{21}H_{21}NO_6$; 13. *Narcotine*, $C_{22}H_{23}NO_7$; 14. *Oxynarcotine*, $C_{22}H_{23}NO_8$; 15. *Narceine*, $C_{23}H_{29}NO_9$; 16. *Pseudomorphine*, $C_{34}H_{36}N_2O_6$; 17. *Gnoscopine*, $C_{22}H_{23}NO_7$; 18. *Xanthaline*, $C_{37}H_{36}N_2O_9$; 19. *Tritopine*, $C_{42}H_{54}N_2O_7$; 20. *Hydrocotarnine*, $C_{12}H_{15}NO_3$. In addition to the above list, *Deuteropine*, *Opionine*, *Papaverosine*, and *Porphyroxine* are possible alkaloids that have been announced, but not sufficiently established as yet. Still others, like *Apomorphine* (see p. 189), can be produced from those existing in the opium. At least two acids occur in opium combined with these bases,—*meconic acid*, $C_7H_4O_7$, and *lactic acid*, $C_3H_6O_3$. This latter, supposed by T. and H. Smith to be a peculiar variety of lactic acid, and named by them *thebolactic acid*, was ascertained by Stenhouse to be the ordinary variety. Sulphuric acid is found in the ash along with the bases calcium, magnesium, and potassium. Opium also contains *mucilage*, *pectic matter*, and a *glucose sugar*. The wax gathered from the refuse of opium yielded Hesse *cerotyl palmitate* and *cerotate*. Three neutral principles have, moreover, been extracted from opium,—*meconin* (*opianyl*), $C_{10}H_{10}O_4$, *meconoiosin*, $C_8H_{10}O_2$, and *opionin*, which, according to Hesse, is contained in small quantities in Smyrna opium. The first of these forms prisms which fuse under water at 77° C., or *per se* at 110° C., and boil at 155° C.; the second melts at 88° C., and the third at 227° C. None of these neutral principles contain nitrogen. All the organic bases of opium polarize to the left. (Bouchardat and Boudet, *Journ de Pharm.*, 3e sér., xxiii. 294.)*

Of the principles above mentioned, *morphine* is by far the most important. It is generally admitted to exist in opium united with meconic acid in the state of meconate, and to a certain extent also as a sulphate, although Dr. A. R. L. Dohme (*A. J. P.*, 1891, p. 168) believes that the results of a dialysis of opium show that the morphine is combined with sulphuric acid alone. Of morphine and its preparations we shall treat under another head. (See *Morphina*.)

Narcotine. *Narcotina*, $C_{22}H_{23}NO_7$. It exists in opium, chiefly, at least, in the free state, and is left behind in considerable quantity when the drug is macerated with water. It is white, tasteless, and inodorous, and crystallizes in silky flexible needles, usually larger than the crystals of morphine, fusible at 176° C. (349° F.), and decomposes at higher temperature with evolution of ammonia. Heated to 220° C., the residue which remains is *hemipinic acid*, $C_{10}H_{10}O_6$, insoluble in cold water, soluble in 400 parts of boiling water, in 100 parts of cold and 24 of boiling alcohol, which deposits it upon cooling, and very soluble in ether. The

* M. Lahens, of Toulouse, found glucose in a tincture of poppy capsules, and in all the commercial varieties of opium, in proportions varying from 3 to 14·5 per cent. Its presence in opium is therefore not a proof of sophistication. (*Journ. de Pharm.*, Oct. 1854, p. 265.)

Proportionate quantity of the more important constituents of Opium. The Messrs. Smith, of Edinburgh, obtained from 100 parts of fine opium 10 parts of morphine, 6 of narcotine, 0·15 of thebaine, 1 of papaverine, 0·3 of codeine, 0·02 of narceine, 0·01 of meconin, 4 of meconic acid, and 1·25 of thebolactic acid. (*P. J. Tr.*, Oct. 1865, p. 183.)

fixed and volatile oils, and the diluted acids, also dissolve it; and it has been found to be soluble in the volatile oil of turpentine, which, aided by heat, will extract it from opium, and yield it in crystals by evaporation. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 156.) As it exerts no alkaline reaction upon vegetable colors, and does not prevent the acids from reddening litmus paper, there would appear to be some reason for denying it the rank of an alkaloid. But it unites with some of the acids, forming definite compounds, which may be procured in a separate state; and Robiquet obtained narcotine sulphate and hydrochlorate well crystallized. (*Journ. de Pharm.*, xvii. 639, and xix. 59.) Hence it is now generally considered as a weak base; and perhaps this view of it is the most convenient. It must be admitted, however, to have a very feeble neutralizing power. With acetic acid it does not appear to form a permanent combination; for, though dissolved by cold acetic acid, it is separated by heating the solution. It is decomposed by long boiling, or by heating with nitric acid, into *cotarnine*, $C_{12}H_{13}NO_3$, and *meconin*, $C_{10}H_{10}O_4$, and by heating with water to 100° in sealed tubes, into *hydrocotarnine*, $C_{12}H_{15}NO_3$, and *opianic acid*, $C_{10}H_{10}O_5$; while, on the other hand, the action of nascent hydrogen (from zinc and hydrochloric acid) converts it into *hydrocotarnine* and *meconin*, and that of oxidizing agents into *cotarnine* and *opianic acid*. It may be distinguished from morphine by its insipidity, by its solubility in ether and insolubility in alkaline solutions, by not affecting vegetable colors, by assuming a yellowish instead of a blood-red color under the action of strong nitric acid, by not decomposing iodic acid, and by not producing a blue color with ferric salts. It is, however, reddened by a mixture of nitric and sulphuric acids. Hence, if to a mixture of it with strong sulphuric acid a small piece of potassium nitrate is added, a deep blood-red color is produced; while morphine, under the same circumstances, yields a brownish or olive-green color. It gives a greasy stain to paper when heated upon it over a candle. When distilled with potassa, or simply by heating to 250° C., it yields *trimethylamine*, $N(CH_3)_3$. Heated with strong hydrochloric acid, it loses two groups, CH_2, and with concentrated hydriodic acid a third, CH_2, so that we have established the existence of three methyl groups (CH_3) in narcotine. Water extracts narcotine partially from opium, in consequence of the acid which the latter contains, either free or combined with the narcotine. It is usually obtained mixed with morphine in the processes for procuring that principle, and may be separated by the action of ether, which dissolves it without affecting the morphine, and yields it upon evaporation. It may also be obtained by digesting opium in ether, and slowly evaporating the ethereal solution, which deposits crystals of narcotine. It is said that the same result may be obtained by using the oil of turpentine as the menstruum, first heating it with opium, and then evaporating the solution. Another mode of procuring it is to treat opium, exhausted by previous maceration in water, with dilute acetic acid, filter the solution, precipitate by an alkali, wash the precipitate with water, and purify it by solution in boiling alcohol, from which it crystallizes as the liquid cools. Should it still be impure, the solution in alcohol and crystallization may be repeated. The proportion of narcotine in opium* varies extremely in the different varieties, and in different specimens of the same variety. Thus, in Smyrna opium it has been found by different observers, in quantities varying from 1·30 to nearly 11 per cent. Though narcotine itself is tasteless, its salts are very bitter, even more so than those of morphine. (*Berzelius.*) Their solution reddens litmus, and yields precipitates with the alkalies and infusion of galls. Robiquet obtained the sulphate and hydrochlorate crystallized.†

Different opinions have been advanced relative to the action of narcotine on the system. Derosne believed it to be the active principle of opium; though upon experimenting with it he obtained effects but little stronger than those produced by an equal dose of opium itself. Others found it possessed in different degrees of narcotic properties; and the results of various experiments which led to the conclusion may be seen in former editions of this work. But a more thorough investigation seems to have proved that it cannot be ranked among narcotic medicines. It has been asserted that narcotine is identical with *aconella*, an alkaloid said to

* For physiological study of the methylamide derivatives of narcotine (*narcotine methylamide*), see *Virchow's Archiv*, 142, 1895.

† ANARCOTINE has been described as an alkaloid especially abundant in the India opium. According to Wm. Roberts (*British Med. Journ.*, ii. 1895), whilst Smyrna opium containing 8 per cent. of morphine has in it 2 per cent. of anarcotine, Bengal opium contains 4 per cent. of morphine with 6 per cent. of anarcotine. Anarcotine appears, however, to be simply pure narcotine. (*Merck's Jahresber.*, 1896, 101.) It is said to be nearly destitute of active physiological properties. In the experiments of Surveyor (*British Med. Journ.*, 1896), one drachm of it given subcutaneously to the anæsthetized dog produced no sensible effect. The continuous use of it in large doses seemed, however, to affect the nutrition of the dog. It was at one time largely used in India as an antiperiodic on account of its being cheaper than quinine, but has fallen into desuetude because of the present low price of the cinchona alkaloids.

have been extracted by the Messrs. Smith, of Edinburgh, from aconite; but Groves failed to find aconella. (See page 79, U. S. D., 14th edition.) Narcotine acts feebly upon the lower animals as a convulsant. No cases of fatal poisoning from it in man are on record, but 120 grains of it are said to have been taken without producing distinct results. On the other hand, observers have seen profound narcotism caused by much smaller quantities, these results, however, being without much doubt due to impurities in the drug. According to Leubuscher (*Deutsch. Med. Wochens.*, 1892), it is a feeble sedative to intestinal peristalsis. Many years ago Dr. O'Shaughnessy, of Calcutta, recommended narcotine as an antiperiodic, in doses of three grains (0·19 Gm.) three times a day, but it has failed to acquire reputation.*

Codeine. *Codeia*, $C_{18}H_{21}NO_3$ (or $C_{17}H_{17}NO(OH).OCH_3$), was discovered in 1832 by Robiquet in morphine hydrochlorate prepared according to the process of Gregory, and was prepared synthetically by Grimaux by the action of methyl iodide and caustic soda upon morphine, thus proving its chemical character as methylmorphine. It exists in opium combined like morphine with meconic acid, and is extracted along with that alkaloid in the preparation of the hydrochlorate. (See *Morphina.*) When the solution of the mixed morphine and codeine hydrochlorates is treated with ammonia, the former alkaloid is precipitated, and the codeine, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them, and yields the codeine in colorless crystals by spontaneous evaporation. This alkaloid is now official. (See *Codeina.*)†

Thebaine (*Paramorphia*). *Paramorphine*, $C_{19}H_{21}NO_3$ (or $C_{17}H_{15}NO(OCH_3)_2$), was discovered by Pelletier in the precipitate thrown down from an infusion of opium treated with milk of lime. The precipitate being washed with water till the liquid came away colorless, and then treated with alcohol, instead of affording morphine to this solvent, as was anticipated, yielded a new alkaloid, which was obtained separate by evaporating the alcohol, acting on the residue with ether, allowing the ethereal solution to evaporate spontaneously, and then purifying the resulting crystalline mass by dissolving it in an acid, precipitating by ammonia, and recrystallizing by means of alcohol or ether. Pelletier named it paramorphine, from its close analogy in composition with morphine, from which, however, it is quite distinct in properties. The name of *thebaine* was proposed for it by M. Couërbe, who was disposed to give the credit of its discovery to M. Thiboumery, the director of Pelletier's laboratory. It is white, crystallizable, of an acrid and styptic rather than bitter taste, fusing at 193·4° C. (379·4° F.), and, according to Hesse, confirmed by D. B. Dott, is not sublimable. Other observers state that it sublimes at 135° C. without fusing, and is deposited in minute crystals resembling caffeine. It is scarcely soluble in water, very soluble in alcohol and ether when cold, and still more so when heated, and capable of combining with the acids, with which it forms salts not crystallizable from their aqueous solution. Alkalies precipitate it from its acid solutions, and, unless in very concentrated solution, do not dissolve it when added in excess. It is not, like morphine, reddened by nitric acid, nor does it become blue with solutions of ferric salts. From codeine it differs in never being in large crystals, in not forming crystallizable salts, in being always precipitated from its acid solutions by ammonia, and in not melting in oily drops. From narcotine, which it most resembles, it may be distinguished by its shorter crystals, which lack the pearly appearance of those of narcotine, by its different taste, by its much greater solubility in cold alcohol, of which 10 parts will dissolve 1 of this principle, while narcotine requires 100 parts, and by the action of nitric acid, which converts it into a resin-like matter before dissolving it, while the same acid instantly dissolves narcotine. Diluted sulphuric or hydrochloric acid in excess changes thebaine, according to Hesse, into two isomeric bases, *thebenine* and *thebaicine*. When heated to 90° C. under pressure with fuming hydrochloric acid, thebaine yields a base having the probable formula $C_{17}H_{15}NO(OH)_2$, and called by its discoverer, W. C. Howard (*Ber. Chem. Ges.*, xvii. 527, xix. 1596), *morphothebaine*, to indicate its origin and relation to morphine. Magendie and many subsequent observers agree that thebaine is a powerful spinal convulsant, resembling in its action strychnine. Leubuscher affirms that it is an intestinal stimulant. Eulenberg found one-four-hundredth of a grain sensibly active in man; and the reported failures of large amounts to produce distinct effects have

* For methods of preparation for the *meconate, acetate, hydrochlorate,* and *sulphate of narcotine* by D. B. Dott, see *A. J. P.*, 1884, p. 152.

† *Codeine hydrobromide*, $C_{36}H_{42}N_2O_6,2HBr,4H_2O$, is described by D. B. Dott in *P. J. Tr.*, 1884, p. 917.

Codeine phosphate crystallizes in slender, four-sided columns; it is colorless and of a bitterish taste, and is soluble in four parts of water. Its action, according to Dr. Fronmüller, is like that of morphine, but milder. It seldom causes local irritation when subcutaneously injected, and is more soluble than the sulphate or hydrochlorate. The dose should be at least double that of morphine. (*Amer. Drug.*, 1884, p. 45.)

probably been due to the alkaloid used being impure. On motor nerves it seems to have a paralyzing influence, though in the mammal death takes place from tetanus.

PAPAVERINE. *Papaverina*, $C_{20}H_{21}NO_4$. The discovery of this alkaloid was announced by Dr. G. Merck. It is crystallizable in needles, fusing at 147° C. (296·6° F.), insoluble in water, very sparingly soluble in cold alcohol or ether, more soluble in these liquids boiling hot, and deposited by them on cooling. With acids it forms salts, most of which are very sparingly dissolved by water. The hydrochlorate crystallizes with extraordinary facility. The alkaloid is readily dissolved by moderately concentrated hydrochloric acid, from which, on the addition of more acid, the hydrochlorate separates, assuming the form of an oily layer at the bottom of the vessel, which is readily converted on standing into a mass of acicular crystals. These crystals are very sparingly soluble in cold water. The hydrochlorate yields with platinic chloride a yellow precipitate which is insoluble in boiling water or alcohol. By the action of concentrated nitric acid there is formed, on heating, the nitrate of nitropapaverine, $C_{20}H_{20}(NO_2)$-$NO_4.HNO_3$, which separates in crystals. The nitro-base can be separated in clear yellow flocks by the addition of ammonia. By the action of tin and hydrochloric acid there is formed a tetrahydropapaverine, $C_{20}H_{25}NO_4$. Cold concentrated sulphuric acid does not color it, but on warming a violet color is obtained; an impure papaverine is colored violet, however, with sulphuric acid even in the cold. Papaverine is prepared by precipitating the aqueous infusion of opium with soda, exhausting the precipitate with alcohol, evaporating the tincture to dryness, treating the residue with a dilute acid, filtering, precipitating by ammonia, dissolving the precipitate in hydrochloric acid, mixing sodium acetate with the solution, and treating the resulting precipitate with boiling ether. The ethereal solution deposits the papaverine on cooling. The results obtained by investigators of the physiological action of papaverine seem hopelessly discordant, and any future studies made should be prefixed by an absolute chemical examination of the alkaloid used. Leubuscher (*Deutsch. Med. Wochensch.*, 1892) asserts that it acts as a sedative to intestinal peristalsis without producing other effects, and is valuable in the *diarrhœa* of children. Dose for a two-year-old child, two-fifths of a grain (0·025 Gm.), repeated three or four times a day.

NARCEINE.* *Narceia*, $C_{23}H_{29}NO_9$,† discovered by Pelletier in 1832, is in white, silky crystals, inodorous, of a bitter taste, the fusing point of which was given at 145·2° C. (291·6° F.) according to Hesse, and at 92° C. according to Pelletier. E. Merck has shown, however (*Chem. Zeit.*, 1889, p. 525) that the ordinary commercial alkaloid of English manufacture melts between 150° and 160° C., and the pure base at 170° to 171° C. Out of water at 60° C. it crystallizes with 2 molecules of water, which it loses at 100° C., and at 140° C. another molecule of water escapes, leaving in the fused residue a mixture of bases. Soluble in 375 parts of cold and 220 of boiling water, soluble also in alcohol, and insoluble in ether. It forms a bluish compound with iodine, the color of which is destroyed by heat and the alkalies. Besides, according to Stein, the blue color is not produced when there is too much of the iodine present, which then causes a brown color with narceine; the blue color appearing, under such circumstances, only when the excess of iodine is saturated by ammonia. (*Journ. de Pharm.*, Janv. 1872, p. 59.) It is rendered blue by the action of mineral acids so far diluted as not to decompose it, but does not, like morphine, become blue by the action of ferric salts, nor red by that of nitric acid. According to Prof. P. C. Plugge, if a trace of narceine be covered in a porcelain capsule with *diluted* sulphuric acid, no change will be observable; but if the capsule be heated on the water-bath, a blue color will be developed as soon as the acid has become sufficiently concentrated; this by prolonged heating will pass to cherry-red. If to this red liquid, after cooling, a trace of nitric acid or of potassium nitrite be added, blue-violet streaks will be produced. (*Archiv d. Pharm.*, 1887, p. 425.) It is dissolved by the acids, but was thought not to neutralize them, and, though at first considered alkaline by Pelletier, was afterwards ranked with indifferent bodies. At present, however, its alkaloidal character is admitted; it unites with sulphuric acid to form a crystallizable sulphate. (*Journ. de Pharm.*, Avril, 1864, p. 367.) Dr. Dragendorff has announced that solution of narceine gives a crystalline precipitate with the double zinc and potassium iodide. This reaction may be employed with iodine as a test of narceine. If a solution of this salt, with a little iodized water, be added to solutions of nar-

**Aponarceine*, $C_{23}H_{27}NO_8$, a patented derivative, is made by heating narceine with a concentrated alkali hydroxide solution, dissolving the alkaline salt produced in alcohol, and treating this solution with an alcoholic solution of an acid.

† Freund and Frankforter believe that this formula of Anderson's should be modified to $C_{23}H_{27}NO_8$. (*Ann. der Chem.*, 1893, 20.)

ceine, and the mixture then agitated with ether to remove the iodine in excess, a solution containing a very small quantity of narceine will distinctly assume a blue color. The other alkaloids of opium are destitute of this property. (*Journ. de Pharm.*, Avril, 1870, p. 346.) Pelletier obtained it in the course of his analysis of opium. Having formed an aqueous extract of opium, he treated it with distilled water, precipitated the morphine by ammonia, concentrated the solution, filtered it, threw down the meconic acid by baryta water, separated the excess of baryta by ammonium carbonate, drove off the excess of the ammoniacal salt by heat, evaporated the liquor to the consistence of syrup, set it aside till a pulpy matter formed containing crystals, separated and expressed this pulpy matter, then treated it with alcohol, and concentrated the alcoholic solution. This, on cooling, deposited crystals of narceine, which were easily purified by repeated solution and crystallization. Meconin, which often crystallizes with it, may be separated by the agency of ether. The discordancy of the statements of physiologists and clinicians concerning the action of narceine can only be explained by the presence of impurities in the specimens used. The pure alkaloid would seem to be very feeble in its influence, Mitchell having taken five grains without any other effect than causing some headache. The narceine of commerce has been used in doses of one-third to three-quarters of a grain (0·02 to 0·05 Gm.) as a mild narcotic, probably acting through contaminating morphine.*

Oxynarcotine. *Oxynarcotia*, $C_{22}H_{23}NO_8$. This alkaloid accompanies narceine, from which it can be separated by treating the mixture with dilute sulphuric acid. On neutralizing the solution with the theoretical amount of soda and heating to boiling, a part dissolves. The undissolved residue is the oxynarcotine. It can also be obtained from the mother-liquors of narcotine. According to Beckett and Wright, it crystallizes out of alcohol in very fine needles, which are difficultly soluble in boiling water and boiling alcohol, insoluble in other neutral solvents. Heated to 140° or 150° C., it is carbonized. It is oxidized by ferric chloride to *hemipinic acid* and *cotarnine*. (See Part II.) It is a monacid base, and forms crystallizable salts.

Hydrocotarnine. *Hydrocotarnia*, $C_{12}H_{15}NO_3$, is obtained from the mother-waters of thebaine, after the removal of cryptopine and protopine with warm benzin, by precipitation with ammonia; laudanosine, which is also precipitated, is removed by treatment of the benzin solution with sodium bicarbonate. The hydrocotarnine is retained in solution by the benzin, from which the laudanosine has been deposited on cooling. Hydrochloric acid gas being made to pass through this solution, hydrocotarnine hydrochlorate crystallizes out. This alkaloid, as the name indicates, can be formed from cotarnine, by the action of zinc and hydrochloric acid. It also seems to result from the decomposition of narcotine. (See *Narcotine*.) If the latter be made to boil some time with baryta water, a portion of it will be decomposed, giving rise to a crystallizable matter, soluble in ether, which appears to be identical with hydrocotarnine. This alkaloid is very soluble in alcohol, acetone, chloroform, benzin, and ether. It melts at 50° C. (122° F.), and loses at 57° C. the half molecule of water with which it crystallizes. Sulphuric acid dissolves it, coloring it yellow in the cold, and crimson-red if heated. Nitric acid colors it yellow; ferric chloride does not affect its color. It has been physiologically studied by Stockman and Dott (*Brit. Med. Journ.*, Jan., 1891), who find that it produces in the lower animals symptoms similar to those caused by narcotine.

Pseudomorphine. *Pseudomorphia*, $C_{34}H_{36}N_2O_6$, was discovered by Pelletier in 1835, and is said by Hesse to be identical with Polstorff's *oxydimorphine;* but, as it exists in small quantities, and was thought to be only an occasional ingredient in opium, little attention has been paid to it. An interesting fact, however, in relation to it, and one of some toxicological importance, is that it possesses two properties considered characteristic of morphine, those, namely, of being reddened by nitric acid and of striking a blue color with ferric salts, and yet it is without any poisonous influence upon the animal economy. (*Journ. de Pharm.*, xxi. 575.) Hesse has investigated the subject, with the following results. He found that it accompanies morphine procured by Gregory's method, and may be separated from that alkaloid by adding ammonia in excess to an alcoholic solution containing both. The morphine is precipitated, and pseudomorphine, remaining in solution, may be obtained by evaporating the mother-liquid. It is tasteless, insoluble in water, alcohol, ether, chloroform, and diluted sulphuric acid, but easily soluble in solution of potassa, soda, and lime, and in alcoholic solution of ammonia, though sparingly in an aqueous solution of the last-mentioned alkaloid. It does not neutralize hydrochloric acid, dissolves in concentrated sulphuric acid with the production of an olive-green

* The remaining alkaloids of opium are not used in practical medicine, and the statements concerning their physiological actions are so contradictory and uncertain that the reader is referred for a detailed discussion of them to H. C. Wood's *Therapeutics*.

color, in concentrated nitric acid with an intense orange-red, and in solution of ferric chloride with a blue color. At 120° C. (248° F.) it loses two molecules of water of crystallization, and at higher temperatures is decomposed without melting. It forms sparingly soluble salts with sulphuric, nitric, oxalic, and tartaric acids, and a crystalline deposit, very slightly soluble in hydrochloric acid, with solution of corrosive sublimate. (*Chem. News*, April 12, 1867, p. 188.) Hesse is of the opinion that pseudomorphine is identical with the oxymorphine prepared by the action of oxidizing agents upon morphine by Schutzenberger.

Protopine.* *Protopia*, $C_{20}H_{19}NO_5$, is an alkaloid which Hesse separated from cryptopine. Both are precipitated as insoluble hydrochlorates by hydrochloric acid in excess; but if the precipitate be dissolved by an excess of oxalic acid, the acid cryptopine oxalate will crystallize, and protopine remain in the mother-waters. The liquid is separated, precipitated by ammonia, and agitated with ether; and the ethereal solution is taken up by hydrochloric acid. Protopine hydrochlorate being dense and granular, while cryptopine hydrochlorate is very light, the two are separated by levigation,—eighty grammes of crude cryptopine furnishing one and a half of protopine. Separated from the hydrochlorate by ammonia, protopine constitutes a crystalline powder, insoluble in water, soluble in alcohol and in hot benzin and acetone, more soluble in chloroform, insoluble in the alkalies generally, but slightly soluble in ammonia. It melts at 202° C. (395·6° F.), undergoing decomposition, and is in anhydrous crystals. Ferric chloride does not color it; nitric acid colors it yellow; sulphuric acid dissolves it, coloring it first yellow, then red, and lastly violet. The alcoholic solution has an alkaline reaction. The salts are neutral and crystallizable.

Laudanine. *Laudania*, $C_{20}H_{25}NO_4$, as first prepared, is mixed with cryptopine, from which it is separated by dissolving it in acetic acid, and adding a slight excess of diluted solution of soda, by which the cryptopine is entirely precipitated. The liquid being filtered, and treated with ammonium chloride, lets fall the laudanine, which soon assumes the crystalline form. The acetate, with the addition of potassium iodide, gives rise to laudanine hydriodate, from which ammonia separates the base perfectly pure. It crystallizes from its solution in boiling alcohol in transparent granules or hexagonal prisms melting at 166° C. It is lævo-rotatory, tasteless, and poisonous, the hydrochloride resembling strychnine in its effects. It is dissolved at 18° C. (64·4° F.) by 647 parts of ether. Sulphuric acid gives with it characteristic reactions. When pure, at common temperatures it assumes a pale rose color, and at 150° C. (302° F.) a reddish violet. When ferric oxide is added, it exhibits the same changes, but with much greater intensity. Laudanine is an energetic base, and with potassa forms a crystallizable compound. Its salts, except the neutral sulphate, oxalate, and tartrate, are crystallizable.

Codamine. *Codamia*, $C_{20}H_{25}NO_4$, is isomeric with laudanine, but is readily distinguished from it by the effect of ferric chloride and nitric acid, both of which color it deep green. It is in anhydrous crystals. It can be purified by taking advantage of the feeble solubility of its iodide. Having decomposed this salt by ammonia, dissolve the precipitate in ether, wash the ethereal solution with solution of sodium bicarbonate, then filter through animal charcoal. By evaporation the liquid deposits the alkaloid in beautiful colorless crystals. Codamine crystallizes also from benzin; but thus obtained it melts at 126° C. (258·8° F.), while that procured through ether melts at about 120° C. (248° F.). The acid iodide, tartrate, and oxalate are crystallizable.

Rhœadine, $C_{21}H_{21}NO_6$, discovered by Hesse in 1865, is crystallizable, but not distinctly alkaline. It fuses at 232° C., and can be sublimed at higher temperatures. It is nearly insoluble in ether, alcohol, benzol, chloroform, water, and ammonia. Its solutions in dilute acids acquire an intense purple color on addition of strong hydrochloric or sulphuric acid, due to the formation of a coloring matter. This is destroyed by alkalies and restored by acids, and is so intense that 1 part of rhœadine will color 10,000 parts of water purple-red, 200,000 deep rose-red, and 800,000 distinctly red, although only a portion of the base is converted into coloring matter. The solution then filtered through bone-black shows the presence of a base, *rhœagenine*, isomeric with rhœadine, but fusing at 223° C. and forming a different series of salts. This alkaloid occurs also in *Papaver rhœas*.

Meconidine, $C_{21}H_{23}NO_4$, was discovered by Hesse in 1870. It is brownish yellow, amorphous, alkaline, melts at 58° C. (136·4° F.), and is not stable, the salts also being easily altered. It is easily soluble in alcohol, ether, benzene, chloroform, and acetone. It is dissolved by sulphuric acid with an olive-green color, and by nitric acid with an orange-red.

* E. Schmidt (*Archiv d. Pharm.*, 231 (1893), 136) states that protopine is identical with the *macleyine* found by Eykman in *Macleya cordata*, and that it is also found in *Sanguinaria canadensis*, *Stylophoron diaphyllum*, and *Escholtzia californica*.

Cryptopine. *Cryptopia*, $C_{21}H_{23}NO_5$. The discovery of this alkaloid was announced by Messrs. T. and H. Smith, of Edinburgh, in *P. J. Tr.*, 1867 (p. 595). The Messrs. Smith obtained it from the weak alcoholic washings of crude morphine after precipitation, by first neutralizing the liquid with diluted sulphuric acid, and then, after recovering the alcohol by distillation, and washing out the still copiously with hot water, by precipitating the mixed liquor of the still and the washings by milk of lime in large excess. The liquid is then filtered off, and the pitch-like precipitate, having been thoroughly washed, is boiled with alcohol in large quantity, the solution filtered, and the alcohol distilled off. The pitchy substance which remains in the retort, and which consists mainly of thebaine, is separated from the supernatant aqueous liquid, and heated to ebullition with enough alcohol to dissolve it. The solution, having been put aside, will be found in a day to have set into a mass of crystals, which consist of crystallized thebaine. This mass is now strongly pressed in a cloth, and the residuary cake powdered and dissolved in diluted hydrochloric acid, care being taken that the acid be not in excess. The filtered liquid is evaporated and crystallized, and the process of evaporation and crystallization repeated, so as to separate all the thebaine hydrochlorate. If now the mother-waters be set aside, the cryptopine hydrochlorate will in the course of some weeks crystallize out of them, but mixed with crystallized thebaine hydrochlorate; and the separation of the two is extremely difficult. But as the crystals of the two alkaloids are very different, those of thebaine being hard and strong, those of cryptopine soft and generally tufted, by careful management, and by repeating the crystallization many times, so as to get rid of most of the thebaine, the cryptopine hydrochlorate may be seen forming on the surface of the harder salt in the solution. The mother-liquors being now poured off, and allowed to evaporate spontaneously, the whole at length sets into a soft mass, which, being pressed in a cloth, is found to consist of almost pure cryptopine hydrochlorate. To obtain the pure alkaloid, it is to be precipitated from the solution of ammonium chloride, then washed, dried, and finally washed with ether or alcohol, which readily dissolves thebaine, but has little effect on cryptopine. It may be obtained in a crystallized state by boiling it with a large quantity of alcohol, which, on cooling, will slowly deposit the alkaloid in crystals. The quantity in opium is extremely small.

Cryptopine is without color or smell; and its salts, though at first bitter to the taste, afterward cause a sense of coolness in the mouth, like that produced by peppermint. It melts at 217° C., and, on cooling, crystallizes in radiated forms at 171° C., and, heated to redness, is decomposed, blackening and giving forth aqueous vapors, but without properly subliming. It is insoluble in water and in ether, very sparingly soluble in alcohol, requiring 1265 parts of that liquid when cold to dissolve it. Chloroform dissolves it almost as freely as narcotine. Oil of turpentine and benzene do not appear to dissolve it. It has very strong alkaline powers, and forms crystallizable salts with the acids, which are distinguishable from all the other salts of the opium alkaloids by a strong tendency to gelatinize. If the hydrochlorate be dissolved in about 30 parts of hot water, and set aside, instead of crystallizing, it forms a jelly closely resembling that of pure gelatin. From all the constituents of opium, except the stronger alkaloids, morphine, codeine, and thebaine, it is distinguished by its strong alkaline properties, as it neutralizes the strongest acids. From morphine it is distinguished by its very sparing solubility in alcohol, and from codeine and thebaine by its total insolubility in ether. It differs also in the effect of strong sulphuric acid, which produces a blue color with the minutest quantity of cryptopine, a blood-red with thebaine, and none with morphine or codeine. The tendency of its salts to gelatinize is another distinguishing property of cryptopine.

Laudanosine. *Laudanosia*, $C_{21}H_{27}NO_4$, exists in the mother-waters of thebaine, with cryptopine and protopine. The thebaine having been precipitated by tartaric acid, the mother-water is neutralized by ammonia, and sodium bicarbonate is added. After eight days' rest, a blackish mass separates. The limpid liquid with an excess of ammonia yields a copious precipitate, which, agitated with heated benzin, gives to that liquid a mixture of several alkaloids. The benzin solution, upon cooling to 40° C. (104° F.), deposits the cryptopine and protopine. On agitation anew with heated sodium bicarbonate and subsequent complete refrigeration, the laudanosine crystallizes. It is entirely purified by ether, which dissolves it abundantly; and its iodohydrate is but slightly soluble in water. It is itself insoluble in water and the alkalies, but it is soluble in alcohol, acetone, and chloroform. It melts at 89° C. (192·2° F.), and is decomposed at 110° C. (230° F.). Ferric chloride does not color it. Sulphuric acid gives it a rose color in the cold, and violet when heated. Nitric acid transforms it into a nitro-base. The crystals are anhydrous. It forms crystallizable salts, which are soluble and bitter.

Color Reactions of the more important Opium Bases (Allen, *Commerc. Org. Anal.*, 2d ed., vol. iii., Part II., p. 302).*

Alkaloid.	Nitric Acid (sp. gr. 1·42).	Concentrated Sulphuric Acid.			Erdmann's Test (sulphuric acid with dilute nitric).	Froehde's Reagent (sulphomolybdic acid).	Ferric Chloride.
		Alone.	On adding $KClO_3$ or HNO_3.	With Sugar.			
Morphine . .	Orange-red, turning yellow on heating.	Cold; no color, or faint pink; on heating, variable (dirty green to black).	Rose-red, or blood-red.	Purple, changing to deep red.	. . . . .	Fine violet, turning blue or dirty green.	Greenish blue.
Apomorphine . . .	Blood-red, or reddish violet.	No color (or violet to brown).	. . . . .	No reaction.	. . . . .	Deep green, turning violet.	Rose-pink, changing to violet and black.
Pseudomorphine .	Orange-red, changing to yellow.	Cold; no color, or olive-green; heated, dingy, green or purple, finally red.	. . . . .	Olive, then dark green, changing to brown.	. . . . .	Violet, changing to blue and green.	Blue.
Codeine . .	Yellow, not changing to red.	No color; dirty brownish green on heating.	Blue on warming.	Cherry-red, changing to violet.	Blue on warming.	Dirty green, changing to blue and pale yellow.	No color.
Thebaine . .	Yellow.	Blood-red, turning orange-yellow; olive-green on heating.	Same as with sulphuric acid alone.	. . . . .	Orange-red.	Blood-red, turning orange-yellow and colorless.	No color.
Papaverine .	Yellow.	Cold; little change; on strongly heating, violet blue, afterwards fading slowly.	No change.	. . . . .	Dull purple.	Green (changing to violet blue), becoming blue and yellow.	No color.
Narcotine . .	Red.	Darkens; changing to orange and brick-red on gently heating.	Carmine-red.	Fine mahogany-brown.	On warming, pink, changing to orange-red, and violet.	Pink, changing to greenish yellow and orange.	No color.
Narceine . .	Yellow, fading rapidly.	Brown, dissolving to yellow solution (changing to dark red). If impure, red or blue color.	No change.	Not characteristic.	Brownish yellow, becoming mahogany-brown on heating.	Brownish green, changing to yellow and reddish (yellow-brown to blue).	. . . . .

* The following table (from Stohmann and Kerl's *Chemie*, 4th ed., 1888) shows the behavior of the more important alkaloids with the chief alkaloidal reagents:

	Morphine.	Codeine.	Narcotine.	Thebaine.	Papaverine.	Narceine.
Phosphomolybdic acid.	Pale-yellow flocky precipitate, soluble in ammonia with blue color.	Brown voluminous precipitate only in concentrated solution.	Brownish-yellow flocky precipitate.	Yellow flocculent precipitate.	No reaction.	Brownish-yellow precipitate, becoming resinous in concentrated solution.
Phosphoantimonic acid.	No reaction.	Dirty-white turbidity.	Pale-yellow flocculent precipitate.	White gelatinous precipitate.	White curdy precipitate.	No reaction.
Potassium iodohydrargyrate.	White gelatinous precipitate.	White curdy precipitates.			Yellowish-white precipitate.	White turbidity, soon turning to resinous lumps.
Potassium iodobismuthate.		Orange precipitates.			Faint turbidity.	
Platinic chloride.	Yellow curdy precipitate, becoming crystalline.	Clear-yellow flocculent precipitates.			White precipitate.	Gradually forming yellow crystalline precipitate.
Mercuric chloride.	No reaction.	Whitish turbidity.	No reaction.	White flocculent precipitate.	Whitish turbidity.	No reaction.
Gold chloride.	Yellowish-brown precipitate, turning resinous.	Flesh-colored precipitate.	Pale-yellow flocculent precipitate.	Flesh-colored precipitate.	Pale-yellow flocculent precipitate.	Yellowish-brown precipitate, turning resinous.
Iodine in potassium iodide.	Reddish-brown precipitates with all.					
Tannic acid.	White turbidity in concentrated salt solutions only.		White flocculent precipitates.		Yellowish precipitate.	White turbidity, in concentrated solutions only.

LANTHOPINE. *Lanthopia*, $C_{23}H_{25}NO_4$, differs from pseudomorphine in not becoming blue with ferric chloride, and in giving, when entirely pure, with sulphuric and nitric acids, colorless solutions. It forms colorless microscopic prisms, which fuse at about 200° C. Its acid oxalate and tartrate are crystallizable. The alkaloid is crystallizable, does not have an alkaline reaction, is sparingly soluble in hot or cold alcohol, ether, or benzol, but readily soluble in chloroform.*

GNOSCOPINE, $C_{22}H_{23}NO_7$, was found by T. and H. Smith in 1878. They first gave to it the formula $C_{34}H_{36}N_2O_{11}$, but in a later communication (*P. J. Tr.*, 1893, 1794) gave it the simpler formula which makes it an isomer of narcotine. It is crystallizable, melts at 233° C. (451·4° F.), with partial decomposition, is soluble in chloroform and carbon disulphide, slightly so in benzene, not in ether. The salts have an acid reaction.

Xanthaline, $C_{37}H_{36}N_2O_9$, is a base obtained by T. and H. Smith (*P. J. Tr.*, 1893, 772) from the acid mother-liquors resulting from the crystallization of morphine or codeine chlorhydrate.

TRITOPINE, $C_{42}H_{54}N_2O_7$, was discovered in 1890 by Klauder (*Arch. Pharm.*, 228, p. 419). It resembles morphine and laudanine in being soluble in soda solution, but is precipitated in the form of an oil by a large excess of the reagent. Tritopine crystallizes in characteristic anhydrous, transparent, needle-like plates, melting at 182° C., easily soluble in chloroform, but only slightly so in ether. With sulphuric acid it behaves like laudanine. It appears to be a diacid base.

PORPHYROXINE, according to K. L. Dey (*Pharm. Journ.* [3], xii. p. 397), is a definite basic substance, always present in Indian opium, but absent from Turkey or Smyrna opium.

MECONIN, $C_{10}H_{10}O_4$, a neutral principle before referred to, the existence of which was announced in 1832 by M. Couërbe, is identical with a substance discovered several years previously by M. Dublanc, Jr., but of which no account was published. It is perfectly white, in the form of acicular crystals, soluble in about 265 parts of cold and 18 of boiling water, very soluble in alcohol, chloroform, and the essential oils, but only sparingly in ether; fusible under water at 77° C., *per se* at 110° C., sublimable on careful heating, and possessed of a degree of acrimony which favors the supposition that it may not be without action upon the system. It is neither acid nor alkaline, and contains no nitrogen. Meconin is obtained by precipitating the aqueous infusion of opium with ammonia, washing the precipitate with water until the latter nearly ceases to acquire color, mixing the aqueous fluids, evaporating them to the consistence of molasses, setting them aside for two or three weeks, during which a mass of granular crystals is formed, then decanting the liquid, expressing the mass, and drying it with a gentle heat. The meconin may be separated from the mass by treating it with boiling alcohol of 36° Baumé, evaporating so as to obtain crystals, dissolving these in boiling water with animal charcoal, filtering the liquid while hot, and subjecting the crystals formed upon the cooling of the solution to the action of ether, which dissolves the meconin, and yields it in a state of purity by spontaneous evaporation.

* O. Hesse obtained most of the alkaloids announced by him from the black mother-liquors left behind in the process for procuring morphine hydrochlorate, first employed by Dr. Gregory, and adopted by the British Pharmacopœia. This liquor, diluted with an equal volume of water, was precipitated by an excess of ammonia; the clear liquid was exhausted with ether, and this treated as described in *Ann. Chem. Pharm.*, clxxx. 47. (*P. J. Tr.*, Jan. 1872, p. 549.) The method in which these alkaloids were first separated from opium by Hesse was as follows. An aqueous infusion is prepared, and precipitated by caustic soda or lime water in excess. In the liquid, a substance is retained, which may be extracted by ether, and one of the characteristics of which is that it yields with sulphuric acid a purple color. This appears to be the porphyroxine of Merck. This Hesse found to be a mixture of several alkaloids, which he separated in the following manner. The liquid above referred to as containing the coloring matter is well shaken with ether; this, being separated, is acidulated with acetic acid, and the impure acetates are obtained by evaporating off the ether. The residue is mixed gradually with a diluted alkaline solution, and agitated so as to cause the resin which separates to form a mass. After twenty-four hours, the precipitate is separated; the liquid containing the alkaloids is mixed with hydrochloric acid in slight excess, and the alkaloids are then precipitated with ammonia. The whole is now shaken with chloroform, acetic acid is added in slight excess, the chloroform is evaporated, and the residue is neutralized with ammonia. The precipitate produced is reddish-colored, and, though at first resinoid, soon crystallizes. This, which consists of impure lanthopine, is separated by filtration, and the filtered liquid, after twenty-four hours, is mixed with caustic soda, in quantity but very little more than necessary to decompose the ammonia salts in solution. It is then shaken repeatedly with ether to separate codeine, which renders it turbid. This alkaloid is separated more readily by ether than the other alkaloids present, meconidine, codamine, laudanine, and another which the author designated by the letter *x*. Ether does not extract the last-mentioned bases from the solution containing fixed alkali until after ammonium chloride has been mixed with it. When the ethereal solution is allowed to evaporate very slowly, *laudanine* first crystallizes, the other three bases remaining as an almost amorphous mass when the ether has all escaped. But if, before the ether has entirely evaporated, the liquid be mixed with solution of sodium bicarbonate, crystals of *codamine* will be deposited as the ether further evaporates. If the mother-liquor, from which the two alkaloids have been separated, is now treated with acetic acid and sodium chloride, *meconidine hydrochlorate* is precipitated, the base *x* remaining in solution. The latter is quite separated from meconidine by repeatedly dissolving the hydrochlorate in water, shaking it with sodium bicarbonate and ether, and then evaporating off the ether. (*P. J. Tr.*, Sept. 1870, p. 205.)

Meconoiosin, $C_8H_{10}O_2$. This principle was discovered by T. and H. Smith, in 1878, who obtained it from the oil-like liquid containing meconin, which, upon being left to itself for some days, sets into a mass of crystals. These crystals, upon being drained and cautiously washed with cold weak spirit, are to be boiled in a large quantity of water. The filtered liquid gives a crystallization of meconin, and the mother-liquor, when concentrated, and upon being set aside for a time, yields beautiful leaf-like crystalline masses of meconoiosin, fusing at 88° C. (190·4° F.). This principle is neutral, and it may be distinguished from meconin by the following test of T. and H. Smith. "When heated with slightly diluted sulphuric acid, and when the evaporation has reached a certain point, meconin produces a beautiful green color. With meconoiosin, under the same circumstances, the coloration is deep red, becoming purple." This substance has been found by Stockman and Dott (*Brit. Med. Journ.*, Jan. 1891) to be a tetanizant.

Opionin, as before stated, was found by Hesse in small quantities in Smyrna opium. It forms white needles, which melt at 227° C. These are insoluble in water, but dissolve in alkalies, alcohol, and ether.

Meconic Acid, $C_7H_4O_7 + 3H_2O$, is in white crystalline scales, of a sour taste followed by bitterness, fusible and volatilizable by heat, soluble in four parts of boiling water, soluble also in cold water and alcohol, with the property of reddening vegetable blues and forming salts. Its compounds with the earths and heavy metallic oxides are generally insoluble in water. Its characteristic properties are that it produces a blood-red color with ferric salts, a green precipitate with a weak solution of ammoniated copper sulphate, and white precipitates, soluble in nitric acid, with lead acetate, silver nitrate, and barium chloride. It is obtained by macerating opium in water, filtering the infusion, and adding a solution of calcium chloride. Calcium meconate and sulphate are precipitated. The precipitate, having been washed with hot water and with alcohol, is treated with diluted hydrochloric acid at 82·2° C. (180° F.). The calcium meconate is taken up, and, upon the cooling of the liquid, calcium bimeconate is deposited. This is dissolved in warm concentrated hydrochloric acid, which deposits pure meconic acid when it cools. It may be freed from coloring matter by neutralizing it with potassa, decomposing the crystallized meconate thus obtained by hydrochloric acid, and again crystallizing. When heated, it loses first its water of crystallization, and then at 120° C. a molecule of CO_2, and yields *comenic acid*, $C_6H_4O_5$; this at 260° C. or over loses another molecule of CO_2, and yields *pyromeconic acid*, $C_5H_4O_3$. By the action of nascent hydrogen (from sodium amalgam) it yields *hydromeconic acid*, $C_7H_{10}O_7$. Meconic acid has little or no action on the system, and is not used separately in medicine; but its natural relation to morphine requires that it should be understood. The three related compounds, meconic acid, comenic acid, and pyrocomenic acid, are now considered to be derivatives of the fundamental compound *pyrone*, $CO<\begin{matrix}CH=CH\\CH=CH\end{matrix}>O$. Thus, from pyrone, $C_5H_4O_2$, we get *oxypyrone* (pyromeconic acid), $C_5H_3O_2(OH)$, and *oxypyrone-carboxylic* (comenic) *acid*, $C_5H_2O_2(OH)COOH$, and *oxypyrone dicarboxylic* (meconic) *acid*, $C_5HO_2(OH)(COOH)_2$. Pyrone itself is formed when comenic and chelidonic acids are heated to 250° C. Most of the pyrone derivatives are converted by the action of ammonia into pyridone and pyridine compounds.

Meconic acid was formerly recognized by the British Pharmacopœia, but was dropped at the late revision. It appears to be nearly free from active physiological properties. Sertürner took 4·5 grains of sodium meconate, and Grape and Loewer 12 grains of the pure acid, without the production of any symptoms, whilst, according to Mulder, Pereira, Lange, and others, 20 grains of the acid cause no sensible effect in the dog.

Thebolactic Acid, which was discovered by the Messrs. T. and H. Smith, of Edinburgh, appears to be a constant ingredient in opium. These chemists were led to search for it by the consideration that the quantity of meconic acid present is insufficient to saturate the whole of the morphine and other bases, which must, therefore, be neutralized by some other acid. They obtained it from the impure mother-liquid of morphine, after all the alkaloids had been thrown down by the addition of an alkali, by concentrating the liquors to a thick consistence, adding alcohol largely, filtering, precipitating all basic matter by sulphuric acid, filtering again, carefully neutralizing by milk of lime, distilling to recover the alcohol, and finally evaporating the residuary contents of the still to a syrupy consistence. After standing for about a week, the syrupy liquid will be seen to have set into a crystalline mass of calcium thebolactate. This, being purified by repeated solution and crystallization, and by animal charcoal, is decomposed by adding the equivalent quantity of sulphuric acid, and separating the liberated thebo-

lactic acid by means of alcohol. Stenhouse showed that the new acid had the composition of lactic acid and was identical with the common variety, and his results were confirmed by J. Y. Buchanan. (*Ber. Chem. Ges.*, 1870, p. 182.) The ready crystallization of its salts with lime is a characteristic property.

Incompatibles. The substances which produce precipitates with opium do not all necessarily affect its medical virtues; but the *alkalies*, and all vegetable infusions containing *tannic* and *gallic acids*, are incompatible, the former separating and precipitating the active principles, the latter forming with it an insoluble compound.

Morphiometric Assays of Opium. The proportion of morphine which any particular specimen of opium will furnish may be considered as the best test of its value, except that of actual trial upon the system. Good opium should yield not less than 9 per cent. of crystallized morphine when assayed by the official process. The U. S. Pharmacopœia directs that opium, dried at a heat not exceeding 85° C. (185° F.), should contain not less than 13 nor more than 15 per cent. of crystallized morphine when assayed by the official process, which is as follows:

"ASSAY OF OPIUM. *U. S.*

"Opium, in any condition to be valued, *ten grammes;* Ammonia Water, *three and five-tenths cubic centimeters;* Alcohol, Ether, Water, each, *a sufficient quantity.* Introduce the Opium (which, if fresh, should be in very small pieces, and if dry, in very fine powder) into a bottle having a capacity of about 300 C.c., add 100 C.c. of water, cork it well, and agitate frequently during twelve hours. Then pour the whole as evenly as possible upon a wetted filter having a diameter of 12 Cm., and, when the liquid has drained off, wash the residue with water, carefully dropped upon the edges of the filter and the contents, until 150 C.c. of filtrate are obtained. Then carefully transfer the moist Opium back to the bottle by means of a spatula, add 50 C.c. of water, agitate thoroughly and repeatedly during fifteen minutes, and return the whole to the filter. When the liquid has drained off, wash the residue, as before, until the second filtrate measures 150 C.c., and finally collect about 20 C.c. more of a third filtrate. Evaporate in a tared capsule, first, the second filtrate to a small volume, then add the first filtrate, rinsing the vessel with the third filtrate, and continue the evaporation until the residue weighs 14 Gm. Rotate the concentrated solution about in the capsule until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 C.c., and rinse the capsule with a few drops of water at a time, until the entire solution weighs 20 Gm. Then add 10 Gm. (or 12·2 C.c.) of alcohol, shake well, add 25 C.c. of ether, and shake again. Now add the ammonia water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during ten minutes, and then set it aside, in a moderately cool place, for at least six hours, or over night. Remove the stopper carefully, and, should any crystals adhere to it, brush them into the flask. Place in a small funnel two rapidly-acting filters, of a diameter of 7 Cm. plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ethereal solution as completely as possible upon the inner filter. Add 10 C.c. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 10 C.c. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when this has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 C.c. in all. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother-water, and afterwards wash them, drop by drop, from a pipette, with alcohol previously saturated with powdered morphine. When this has passed through, displace the remaining alcohol by ether, using about 10 C.c., or more if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.), until its weight remains constant, then carefully transfer the crystals to a tared watch-glass and weigh them. The weight found, multiplied by 10, represents the percentage of crystallized morphine obtained from the Opium." *U. S.*

The British Pharmacopœia directs that "Any suitable variety of opium may be employed as a source of Tincture of Opium and Extract of Opium of the respective official alkaloidal strengths, provided that when dry it contains not less than 7½ per cent. of anhydrous morphine; but, when otherwise used for officially recognized purposes, opium must be of such a strength that when dried and powdered, the powder heated to 212° F. (100° C.) until it ceases

to lose moisture, and the product tested by the appended method, such dry powder shall yield not less than 9½ per cent., and not more than 10½ per cent. of anhydrous morphine. Opium yielding when dried more than 10 per cent. of anhydrous morphine may be diluted to that percentage with any opium containing when dry between 7½ and 10 per cent. of anhydrous morphine, or with Milk Sugar."

"ASSAY OF OPIUM. *Br.*

"Opium, dried at 212° F. (100° C.) and in No. 50 powder, 14 *grammes;* Calcium Hydroxide, freshly prepared, 6 *grammes;* Ammonium Chloride, 4 *grammes;* Alcohol (90 per cent.), Ether, Distilled Water, of each *a sufficient quantity*. Triturate together the Opium, *calcium hydroxide*, and 40 cubic centimetres of *water* in a mortar until a uniform mixture results; add 100 cubic centimetres of *water* and stir occasionally during half an hour. Filter the mixture through a plaited filter, about 10 centimetres in diameter, into a wide-mouthed bottle having a capacity of about 300 cubic centimetres, and marked at exactly 104 cubic centimetres. until the filtrate reaches this mark. To the filtered liquid (representing 10 grammes of opium) add 10 cubic centimetres of *alcohol* (90 per cent.) and 50 cubic centimetres of *ether;* shake the mixture; add the *ammonium chloride*, shake well and frequently during half an hour; set aside for 12 hours for the morphine to separate.* Counterbalance two small filters; place one within the other in a small funnel in such a way that the triple fold of the inner filter shall be superposed upon the single fold of the outer filter; wet them with *ether;* remove the ethereal layer of the liquid in the bottle as completely as possible by means of a small pipette, transferring the liquid to the filter; rinse the bottle with 20 cubic centimetres of *ether*, again transferring the ethereal layer. by means of the pipette, to the filter; wash the filter with a total of 10 cubic centimetres of *ether*, added slowly and in portions. Let the filter dry in the air, and pour upon it the contents of the bottle in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the bottle with *morphinated water*,† until the whole has been removed. Wash the crystals with *morphinated water* until the washings are free from color; allow the filter to drain, and dry it, first by pressing between sheets of bibulous paper, afterwards at a temperature between 131° and 140° F. (55° and 60° C.), finally at 230° F. (110° C.) for 2 hours. Weigh the crystals in the inner filter, counterbalancing by the outer filter. Take 0·5 gramme of the crystals and titrate with *decinormal volumetric solution of sulphuric acid* until the liquid, after boiling, slightly reddens *blue litmus paper*. 1 cubic centimetre of this *volumetric solution* represents 0·0283 gramme of pure anhydrous morphine. The weight of pure anhydrous morphine indicated by the titration, plus 0·104 gramme (representing the average loss of morphine during the process), should amount in total to 1 gramme, that is to say, to a total of not less than 0·95 gramme and not more than 1·05 grammes, corresponding to about 10 per cent. of anhydrous morphine in the dry powdered opium." *Br.*

The U. S. 1880 and Br. methods of assay are practically identical in principle, belonging to the class of assays known as "lime processes." Experience has proved that the "lime processes" have objectionable features, depending as they do upon the principle that opium in the presence of lime is treated with a definite quantity of water until the latter has extracted as much as possible of the soluble portions, after which a certain portion of the solution, which is *assumed to represent* a corresponding fraction of the weight of the opium, is weighed or measured off, the morphine determined in it, and the percentage calculated from the quantity found in this fraction. The "lime processes," in the hands of ordinary operators, "register too low," the assay being applied to a proportion of the opium which may or may not be an aliquot part of the whole, but is generally less than it is assumed to be, because no allowance is made for the increase in volume due to the solution of the solid constituents of the opium. That a slight excess of lime was directed in the U. S. P. 1880 assay is conceded: this excess caused loss in the amount of the precipitated morphine by making it soluble in the mother-liquor; the excess of ammonium chloride had the same effect, and the precipitation being directed from a too dilute solution occasioned greater loss than was necessary. These objections, while trifling for many operations, become serious for delicate assays.‡ The U. S. P.

* Braithwaite and Farr state that, after careful experimenting, they find that two hours' maceration is just as effective as twelve hours'. (*P. J. Tr.*, 1886, 398.)

† *Morphinated Water.* "Prepared by digesting pure morphine in chloroform water for seven days at a temperature of 60° F. (15·5° C.), with occasional agitation, so as to obtain a saturated solution of the alkaloid, and filtering from the undissolved morphine." *Br.* 1898.

‡ For a method of eliminating these errors, see a paper by Dr. Charles Rice, *Amer. Druggist*, 1892, 100.

assay of 1890 is based on the method of Dr. E. R. Squibb, which requires the complete exhaustion of the sample of opium of its soluble matter, the concentration of this solution, and the determination of the morphine in it. The morphine is separated in a crystalline form from its combination with its natural acids in the opium solution by the addition of the ammonia water; the alcohol present serves to hold up the coloring matter, whilst the ether facilitates the complete precipitation of the alkaloidal morphine, pure morphine requiring 4000 parts of ether for its solution. Want of space prevents our giving a critical review of the other methods of assay in use: we append, however, Squibb's revised process for assaying opium (1893); it is based upon Flückiger's, and, although it has the reputation of "registering high," this is probably due to the care and attention to detail, whereby unnecessary loss is avoided.* Teschemacher and Smith (*Chem. News*, 1888, pp. 93, 103) criticise severely sev-

* *Squibb's Method of Assaying Opium* (revised 1893).—*Sampling.* Every fifth lump of a case of opium—except the very small lumps, and every tenth lump of these—is separated for sampling. A cone-shaped piece is cut from each of these lumps, the apex of the cone to come from near the centre of the lump. As these are cut out, a small narrow strip is cut from the side of the cone, taking about an equal proportion from its whole length, so as to get a proper relation of quantity from the dry exterior to the moist centre. These strips as taken are collected together in a mass, so as to lose but little moisture by drying, and the cones are returned to the lumps. After a little practice the mass of strips from each case of opium will not much exceed 25 to 30 grammes. It is rolled out into a long cylinder, the two ends doubled in to the centre, and rolled out again, this rolling out and folding in being repeated six times. If the opium be very moist and sticky, a gramme of powdered starch is weighed off and used to cover the surfaces of the hands and table used in the rolling, and this starch is afterwards to be taken account of in weighing off the samples. Two portions, each representing 10 grammes of the opium, are then weighed off from the mass. One of these is flattened out into a thin cake, placed on a tared watch-glass, and dried until it ceases to lose weight at 100° C. (212° F.), for the determination of moisture. The other is taken for the assay. When powdered opium is to be assayed, two portions of ten grammes each are to be weighed off, one for drying and the subsequent check assay and the other for the first assay. Powdered opium should not lose over 4 per cent. in drying at 100° C. (212° F.).

Maceration. The 10 grammes of mass are pulled out and broken into thin pieces, and dropped into a flask of 200 C.c. capacity, 100 C.c. of water added, the whole occasionally well shaken and allowed to stand over-night, then again well shaken. When powdered opium is to be assayed, the 10 grammes of powder are well shaken with 100 C.c. of water, and then an hour or two of maceration is sufficient.

Exhaustion. The well-shaken opium mixture is carefully poured in the centre of a well-wetted, tared filter of strong paper, of 12 Cm., or 4·8 inches, diameter, so folded that the lower part of the cone hangs free in the funnel,—that is, folded for a rather more open angle than that of the funnel used. The filtrate is received in a beaker marked at 150 C.c., and the flask and residue are well washed with water until the filtrate reaches the 150 C.c. mark. By means of a spatula the residue is returned to the flask without breaking the filter, 50 C.c. of water are added, the whole is actively shaken for five minutes and is then returned to the filter, being carefully poured into the centre, so that in draining the residue may be of equal thickness on all sides. This second filtrate is received in a second beaker marked at 150 C.c., and the residue is percolated and washed until the filtrate reaches the mark. In both percolations a large part of the water is dropped from a pipette, held at a height of 5 or 6 inches, upon the edges of the filter and the surface of the residue. When finally drained, the filter and residue are pressed between folds of bibulous paper, dried until they cease to lose weight at 100° C. (212° F.), and weighed, the weight to be stated by percentage for insoluble residue.

Evaporation of the solution. The weaker solution is evaporated first in a tared capsule of 250 C.c. capacity, on a water-bath, to about 10 C.c. The stronger solution is then added to this, and the evaporation continued until the whole is reduced to 14 grammes. This is rinsed round the capsule by a rotary motion until all the rings of extract formed during the evaporation are dissolved, and it is then poured into a tared flask of 100 C.c. capacity. The capsule is then rinsed into the flask with three rinsings of about 2 C.c. of water each time, and finally with enough water in addition to make the entire solution in the flask weigh 20 grammes.

Precipitation. To the 20 grammes of concentrated solution is then added half its weight, or 10 grammes, of alcohol of not less than 91 per cent. (sp. gr. 0·815), and the mixture is well shaken. Then 25 C.c. or 17·5 grammes of ether of not less than 93 per cent. (sp. gr. 0·725) is added, and the mixture again well shaken. To this 3·5 grammes or 3·5 C.c. of water of ammonia of 10 per cent. strength (sp. gr. 0·960) are added, and the mixture is vigorously shaken for ten minutes. Usually within two minutes from the commencement of this shaking out of the morphine, and often within one minute, a sudden change in the sound of the shaken mixture occurs. From a soft, rather oily sound the change is to a sharp rattle, and coincidently with this change a very large proportion of the morphine crystallizes out in crystals as large as particles of fine sand. At the end of the ten minutes' shaking the flask is set aside over-night, or for not less than six hours.

Separation and washing. The ether layer is poured off as closely as possible, and 20 C.c. of fresh ether are added to the contents of the flask and rinsed round without shaking. This is poured off as closely as possible, and 20 C.c. more of fresh ether added, rinsed round, and poured off as before, and this is repeated with a third portion of 20 C.c. of fresh ether. A pair of counterbalanced filters 9 Cm., or 3·6 inches, in diameter, folded at an angle slightly wider than the funnel, and well wetted with ether, then receive the contents of the flask, the upper ether layer being slowly poured in first, so that it may pass through before the paper becomes wetted with the watery solution. When the liquid has nearly drained through from the crystals on the filters, those from the flask are washed out on to the filters by repeated portions of water, about 3 C.c. at a time, until all the crystals are upon the filters. Then water is applied, drop by drop, from a pipette held 3 or 4 inches above the funnel, to the edges of the filters and the surface of the crystals until they are fairly clean and the mother-liquor and washings together do not exceed 50 C.c. Then 5 C.c. of a saturated solution of morphine in 91-per-cent. alcohol is dropped from a pipette, first upon the crystals on the point of the filter, and then upon the edges of the filters, so as to displace all the watery solution and leave them saturated with the alcoholic liquid. Then, before this has time to dry, it is displaced by dropping on, in the same way, 5 C.c. or more of ether. When this has drained through, the filters are closed together upon the crystals in the original folds and pressed between folds of bibulous paper, under weights, for half an hour. The filters are

eral well-known methods of assay, and recommend their own, which does not vary greatly from others in use: indeed, it is difficult to resist the conclusion that the differences in the results arrived at by various operators are largely chargeable to personal error and unfamiliarity with other processes than their own. The present U. S. P. 1890 assay method is unquestionably the most practical and accurate that has yet been devised. (See *Ephemeris*, June, 1888, 1113; *A. J. P.*, 1887, 74; *Prescott's Organic Analysis*, 1887, 375; *Lyons's Handbook on Assaying Drugs*, 1899, 201.)

For other methods of assay, and comments, see *U. S. Dispensatory*, 14th edition, 675, and 15th edition, 1072; *A. J. P.*, 1876, 358; 1878, 184; 1879, 369; 1894, 445; 1897, 244; *N. R.*, Feb. 1880, Dec. 1880, 1881, 174; *West. Drug.*, 1885, 231, also 1886, 442; *Amer. Drug.*, 1885, 221, also 1886, 203; Dieterich's method modified by Schlickum, *Pharm. Era*, 1887, 325, also 1888, 9; assay adopted by U. S. Laboratory in New York, *Pharm. Era*, 1887, 151; *Brit. and Col. Druggist*, 1894, 372; *P. J. Tr.*, 1897, 542. Gordin and Prescott propose a volumetric assay based on the estimation of morphine as periodide, after separation by treatment with benzole, acetone, and lime water. (*Merck's Report*, 1898, 526.)

Tests of Opium. It is sometimes highly important to be able to ascertain the presence or absence of opium in any suspected mixture. As meconic acid and morphine have been found only in the products of the poppy, if either or both of them be shown to exist in any substance, very strong evidence will be afforded of the presence of opium. The test should, therefore, be applied in reference to the detection of these two principles. If an aqueous infusion of the substances examined yields a red color with the tincture of ferric chloride, there is presumptive evidence of the presence of meconic acid. Greater certainty may be obtained by the following process. Add in excess to the filtered liquor a solution of lead acetate. If opium be present, there will be a precipitate of lead meconate, and the morphine and lead acetates will remain in solution. The precipitate is then to be suspended in water, and decomposed, either by adding a little diluted sulphuric acid, which forms lead sulphate and leaves the meconic acid in solution, or by passing through it a stream of hydrogen sulphide, removing by filtration the precipitated lead sulphide, and heating the clear liquor, so as to drive off the hydrogen sulphide. With the clear liquor thus obtained, if it contain meconic acid, the tincture of ferric chloride will produce a striking red color, ammoniated copper sulphate a green precipitate, and lead acetate, silver nitrate, and barium chloride white precipitates soluble in nitric acid. Potassium sulphocyanate, which, according to Dr. Wright, is an invariable constituent of saliva (*Simon's Chemistry*, ii. 6), produces a red color with ferric salts, resembling that produced by meconic acid; but, according to Mr. Everitt, this color is entirely and at once destroyed by a solution of corrosive sublimate, which has no effect on the red color

then opened, and when the morphine is spread out upon the inner one they are dried at 60° C. (140° F.) until they cease to lose weight. This is the crude morphine, and if a small portion of it is found to be entirely and quickly soluble in one hundred times (or more) its weight of lime water, the weight of the morphine multiplied by 10 is accepted as the percentage of morphine yielded by the opium.

Correction or control of results. When the preliminary testing of a small quantity of the precipitate shows that it is not all entirely soluble in lime water, 0·5 gramme is weighed off, put into a graduated cylinder, and 50 C.c. of lime water added by pouring down the side of the inclined cylinder. The contents of the cylinder are then tilted backward and forward without shaking, so as to avoid the formation of froth on the surface, until all that is soluble is dissolved. Whenever there is doubt as to when the solvent action is complete, the agitation is continued until the undissolved particles cease to diminish in size or number. The solution is then filtered through a pair of counterbalanced filters about 7 Cm., or 2·8 inches, in diameter, and the filters and residue are well washed, first with 5 C.c. of lime water and then with 5 C.c. of water, and when drained they are closed up, pressed between folds of bibulous paper, dried until they cease to lose weight at 100° C., and weighed. Then as 0·5 gramme of the crude morphine is to the weight of this residue, so is the weight of all the crude morphine to the total amount of insoluble residue it would have yielded if the whole had been subjected to the action of 100 times its weight of lime water. The weight thus obtained, subtracted from the total weight of crude morphine, gives the net weight of pure morphine; and this multiplied by 10 gives the corrected percentage.

The lime water solution of 0·5 gramme of morphine and washings are tinted with 10 drops of solution of phenolphthalein, and oxalic acid decinormal solution is dropped in from a burette until the color is discharged. The amount of oxalic acid required indicates the amount of lime water present in the proportion of 40 C.c. of decinormal oxalic acid to 100 C.c. of lime water. The burette is then refilled to the 0 mark for the saturation of the morphine present, and the oxalic acid is dropped in until neutral litmus paper is just slightly reddened. The quantity of the decinormal oxalic acid required should not be less than 16·4 C.c., which indicates, according to the molecular weight of 305·25 for morphine, a degree of purity equal to 100 per cent., or, according to a molecular weight of 303, of 99·4 per cent. These figures and results will, of course, apply only to those assays wherein there are no residues insoluble in lime water. Whenever a correction has to be made, of course the titration applies not to 0·5 gramme of morphine, but to 0·5 gramme less the correction, and then the decinormal solution required will be proportionately less. In general practice, perhaps nineteen times out of twenty the lime water testing will show an insignificant amount of insoluble residue, and then the assay process may well end there, so far as concerns its general practical value and the correction and control of results; and the titration is merely held in reserve for exceptional cases and unusual varieties of opium. (*Ephemeris*, vol. iii. p. 1152.)

of the iron meconate. (*A. J. P.*, xii. 88.) On the contrary, gold chloride reddens a solution of sulphocyanic acid or a sulphocyanate, but not of meconic acid. Pereira says the acetates also redden ferric salts, but do not afford the results just mentioned with lead acetate and barium chloride. To test the presence of morphine, the liquid from which the lead meconate has been precipitated, and which may be supposed to contain the morphine and lead acetates, must be freed from the lead by a stream of hydrogen sulphide, and then from the hydrogen sulphide by heat; after which the following reagents may be applied,—viz., 1, nitric acid, which colors the morphine red; 2, iodic acid, which is decomposed by the morphine with the extrication of iodine, which colors the liquid reddish brown, and, if starch is present, unites with it to form a blue compound; 3, solution of ammonia, which, if carefully added, so as not to be in excess, throws down a precipitate of morphine soluble in a great excess of that alkali or of potassa; and, 4, tannic acid, which precipitates morphine tannate. If the precipitate thrown down by ammonia afford a deep-red color becoming yellow with nitric acid, and a blue color with ferric chloride, the proofs may be considered complete.*

Though opium is little injured by time if well kept, yet it does undergo spontaneous change, and M. Guibourt found less morphine in a specimen which had been in his possession nearly twenty years than it had yielded in its recent state. There was also more coloring matter. (*Ann. de Thérap.*, 1863, p. 5.)

Among the adulterations of opium, starch has been detected in a specimen examined by Mr. J. T. King. The drug was unduly brittle, and evidences of starch were afforded both by the microscope and by iodine. From the size and form of the granules, Mr. King inferred that the starch was that of the bean. (*A. J. P.*, Jan. 1869, p. 1.) The probability is that powdered beans were the substance used.

Medical Properties and Uses. Opium is a stimulant narcotic. Taken by a healthy person in a moderate dose, it increases the force, fulness, and frequency of the pulse, augments the temperature of the skin, invigorates the muscular system, quickens the senses, animates the spirits, and gives new energy to the intellectual faculties. Its operation, while thus extending to all parts of the system, is directed with peculiar force to the brain, the functions of which it excites sometimes even to intoxication or delirium. In a short time this excitation subsides; a calmness of the corporeal actions, and a delightful placidity of mind, succeed, and the individual, insensible to painful impressions, forgetting all sources of care and anxiety, submits himself to a current of undefined and unconnected but pleasing fancies, and is conscious of no other feeling than that of a quiet and vague enjoyment. At the end of half an hour or an hour from the administration of the narcotic, all consciousness is lost in sleep. The soporific effect, after having continued for eight or ten hours, goes off, and is often succeeded by more or less nausea, headache, tremors, and other symptoms of diminished or irregular nervous action, which soon yield to the recuperative energies of the system; and, unless the dose be frequently repeated, and the powers of nature worn out by over-excitement, no injurious consequences will ultimately result. Such is the obvious operation of opium when moderately taken; but other effects, very important from a remedial point of view, are also experienced. All the secretions, with the exception of that from the skin, are in general either suspended or diminished; the peristaltic motion of the bowels is lessened; pain and inordinate muscular contraction, if present, are allayed; and general nervous irritation is composed.

In doses insufficient to produce the full soporific effect, the stimulant influence upon the mental functions continues longer, and the subsequent calming effect is sustained for hours, sleep being not unfrequently prevented, or rendered so light and dreamy that, upon awaking, the patient will scarcely admit that he has slept at all. From large doses the period of excitement and exhilaration is shorter, the soporific and anodyne effects are more intense and of longer duration, and the succeeding symptoms of debility are more obvious and alarming.

By quantities sufficient to destroy life, after a brief excitement, the pulse is reduced in frequency, though not in force, muscular strength is diminished, and feelings of languor and drowsiness supervene, which soon eventuate in a deep apoplectic sleep. A stertorous respira-

* Merck has proposed a test of opium, founded on the property, which characterizes porphyroxine, of assuming a red color when heated in diluted hydrochloric acid. The suspected liquid is first to be carefully evaporated, a few drops of solution of potassa are to be added, and the mixture agitated with ether. The ethereal solution being filtered off, a slip of unsized paper is to be dipped into it and dried; and the moistening and drying should be repeated several times. The paper thus prepared is to be moistened with diluted hydrochloric acid, and then exposed to the vapor of boiling water. If it become reddened, opium may be inferred to exist in the liquid tested. Heusler states that this test is not applicable to the aqueous solution or extract of opium, because porphyroxine is insoluble in water; but Mr. Robertson, of Rotterdam, has found it to succeed with the aqueous extract, and infers that the porphyroxine is so combined in opium as to render it in some measure soluble. (*Journ. de Pharm.*, 3e sér., xxii.)

tion, a dark suffusion of the countenance, a full, slow, and laboring pulse, an almost total insensibility to external impressions, and, when a moment of consciousness is obtained by violent agitation or irritating applications, a confused state of intellect, and an irresistible disposition to sink back into comatose sleep, are symptoms which, for the first few hours, attend the operation of the poison. The pulse is slow, but is full and strong. In the space of a few hours, varying according to the quantity of the narcotic taken and the powers of the patient's constitution, a condition of debility ensues; and this condition will be hastened in point of time, though it will be more under the control of remedies, if the opium be evacuated from the stomach. Called to an individual laboring under the influence of a fatal dose of opium, at a period from six to twelve hours after it has been swallowed, the practitioner will generally find him with a cool, clammy skin, cold extremities, a pallid countenance, a feeble, thread-like, scarcely perceptible pulse, a slow, interrupted, almost gasping respiration, and a torpor little short of absolute, death-like insensibility. Death soon follows, unless relief be afforded.

After death from opium there are no characteristic lesions discoverable. The active principles of opium are undoubtedly absorbed, and act directly upon the nerve-centres, affecting in man chiefly the cerebrum, but in some of the lower animals the spinal system more profoundly than the brain. The slow, full pulse seen early in the poison is due to an excitement of the pneumogastric centres in the medulla, whilst the rapidity of the pulse late in the poisoning is probably, in part at least, the result of a paralysis of these centres. The great feebleness of the pulse seems to be partially produced by vaso-motor paralysis, partially by exhaustion of the intra-cardiac ganglia. The contraction of the pupil is caused by stimulation of the oculo-motor centres, whilst the sudden dilatation which immediately precedes dissolution seems to have its origin in a giving out of these centres. The immediate cause of death is failure of respiration, which is due to a direct action of the poison upon the respiratory centre in the medulla oblongata.

On some individuals opium produces peculiar effects, totally differing from the ordinary results of its operation. In very small quantities it occasionally gives rise to excessive sickness and vomiting, and even spasm of the stomach; in other cases it produces restlessness, headache, and delirium; and we have known it, even in large doses, to occasion obstinate wakefulness. The headache, want of appetite, tremors, etc., which usually follow, in a slight degree, its narcotic operation, are uniformly experienced by some individuals to such an extent as to render the use of the medicine very inconvenient. It is possible that some of these disagreeable effects may arise not from the meconate of morphine contained in the opium, but from some other of its ingredients; and those which do result from the meconate may not be produced by other salts of morphine. It is very commonly believed that narcotine is the most depressant of all the active principles. As water does not dissolve it, aqueous preparations of opium are least apt to cause unpleasant after-effects.

An occasional effect of opium, which has not yet been mentioned, is a disagreeable itching or sense of pricking in the skin, sometimes attended with a species of miliary eruption. We have found the effect to result equally from all the official preparations of this narcotic.

The local effects of opium are similar in character to those which follow its general operation. An increased action of the part is first observable; then a diminution of its sensibility and contractility; and the latter effect is more speedy, more intense, and of longer continuance, the larger the quantity applied.

In all parts of the world, opium is habitually employed by many with a view to its exhilarating and anodyne influence. This is particularly the case among the Mohammedans and Hindoos, who find in this narcotic the most pleasing substitute for alcoholic drinks, which are interdicted by their religion. In India, Persia, and Turkey it is consumed in immense quantities; and many nations of the East smoke opium as those of the West smoke tobacco. This is not the place to speak of the fearful effects of such a practice upon both the intellectual and the bodily faculties.

The use of opium as a medicine can be clearly traced back to Diagoras, who was nearly contemporary with Hippocrates; and it was probably employed before his time. Its extensive applicability to the cure of disease will be rendered evident by a view of the indications which it is calculated to fulfil. 1. It is excitant in its primary action. In *low or typhoid complaints*, requiring a supporting treatment, it exalts the action of the arterial and nervous systems, and, in moderate doses frequently repeated, may be employed with advantage in conjunction with other stimulants. 2. It is still true that as a general analgesic opium is the most effectual drug known, although in some forms of *neuralgia*, in *migraine* and other *nervous headaches*, as well as in the fulgurant *pains* and *crises* of spinal scleroses, antipyrin, phenacetin,

and other coal-tar products, especially in combination with caffeine, are often preferable to it. When the pain is severe the opium should be given in the form of a morphine salt, hypodermically injected. 3. Opium is an important somnifacient, and when the sleeplessness is produced by pain is the most useful drug of the class. In ordinary insomnia, trional, sulphonal, chloral, or other of the modern hypnotics are usually to be preferred. Very frequently, as in *delirium tremens*, the combination of opium with these narcotics is especially effective. 4. Opium acts as an antispasmodic, probably by benumbing the sensitiveness of the peripheral or centric nerve system, and hence is useful in *tetanus*, *colic*, *gouty spasm of the stomach*, *cholera*, *nephritic* and *hepatic colic*, and in various convulsive affections. 5. It is useful in allaying various irritations, such as produce excessive *cough*, *nausea*, *tenesmus*, *strangury*, etc. In this way it is valuable in various *internal hemorrhages* in combination with more directly acting remedies. 6. It is often very serviceable in checking morbid discharges, as in serous or other forms of *diarrhœa* with very large liquid stools, also in *diabetes*. 7. Combined with ipecacuanha, it is often useful as a diaphoretic (see *Pulvis Ipecacuanhæ et Opii*) in *forming colds*, *subacute rheumatism*, *grippe*, etc.

From this great diversity of properties, and the frequent occurrence of those morbid conditions in which opium affords relief, it is often prescribed in the same disease to meet several indications. Thus, in idiopathic fevers we frequently meet with morbid vigilance and great nervous irritation, combined with a low condition of the system. In *typhoid pneumonia* there is the same depression of the vital powers, combined often with severe neuralgic pains and much nervous irritation. In *diarrhœa*, besides the indications presented by the spasmodic pain and increased discharge, there may be a strong call for the diaphoretic operation of the opium. It is unnecessary to multiply instances.

But a medicine possessed of such extensive powers may do much injury if improperly directed; and conditions of the system frequently occur in which, though some one of the symptoms calls for its use, others, on the contrary, are incompatible with it. It is contra-indicated by inflammation of the brain or strong determination of blood to the head, by deficient secretion from inflamed mucous membranes, as in the early stages of *bronchitis*, and generally by *constipation*. When, however, the constipation depends upon intestinal spasm, as in *colic*, it is sometimes relieved by the antispasmodic action of the opium; and the drying effects of the medicine upon mucous membranes may be counteracted by expectorants or laxatives.

Opium may be administered in substance or in tincture. In the former state it is given in the shape of a pill, which, as a rule, should be formed out of powdered opium, as it is thus more readily dissolved in the liquors of the stomach, and therefore operates more speedily and effectually, than when made, as it sometimes is, immediately from the plastic mass. There is no medicine of which the dose is more variable, according to the habits of the patient, the nature of the complaint, or the purpose to be effected. While in *catarrh* and *diarrhœa* we often prescribe not more than one-fourth or one-third of a grain (0·016 or 0·02 Gm.), in tetanus and some other acute diseases enormous doses are well borne. In acute peritonitis we have seen the equivalent of seventy-five grains (5 Gm.) given during the twenty-four hours with advantage. In using heroic doses it is essential that a liquid preparation be administered in divided doses at short intervals, so as to secure prompt absorption, that the patient be closely watched, and that the remedy be suspended as soon as narcosis begins. In chronic cases, when the system becomes habituated to the remedy, indefinite doses are sometimes borne. The ordinary medium dose of dried or powdered opium may be set down as one grain (0·065 Gm.).

Opium may often be administered with great advantage by the rectum. In this way it operates most advantageously in *obstinate vomiting*, *painful nephritic* and *uterine affections*, *strangury* from blisters, and *dysenteric tenesmus*. It may be employed as a suppository, or in the form of enema made with laudanum and a small quantity of viscid liquid, as flaxseed tea, mucilage of gum arabic, or starch prepared with hot water. Absorption takes place more slowly from the rectum than from the stomach, and a one-half larger dose may be given. In an individual long accustomed to take opium internally, and whose stomach will receive large doses with impunity, it is possible that the rectum may not have lost in a proportionate degree its absorbing power or susceptibility, and that serious consequences might result by adhering, in such a case, to the rule as to the relative quantity to be given in the way of enema or suppository.

In some one of its liquid preparations, opium is often used locally as an addition to collyria in *ophthalmia*, to injections in *gonorrhœa*, and to lotions and cataplasms in various *complaints of the skin*, and external pains, as those of *gout* and *rheumatism*. It is also employed in substance, in the form of a plaster or cataplasm made from the powder. But its external use re-

quires some caution, especially when the skin is deprived of the cuticle. Death is said to have resulted from laudanum applied to the epigastrium. (*Ann. de Thérap.*, 1843, 5.)

Treatment of Opium Poisoning. The value of potassium permanganate as a chemical antidote to opium seems to be thoroughly established. It acts by oxidizing and so destroying the alkaloid. It is evident that to exert this influence it must be brought in contact with the alkaloid, and all our physiological knowledge goes to show that potassium permanganate is not absorbed as such in the blood, but always undergoes decomposition by the organic fluids or even tissues with which it is brought in contact. Further, the allegation that potassium permanganate given hypodermically is an efficient antidote in opium poisoning does not seem to be sustained by the clinical records. It is in fact a chemical antidote to be administered by the mouth. Recent researches have, however, shown that poisonous alkaloids after their absorption are eliminated by the stomach and upper intestines, to be reabsorbed; so that it is important in a case of opium poisoning not to be satisfied with the primary administration of the permanganate, but to continue giving it in small doses until marked abatement of the symptoms is obtained. The stomach should be emptied either by the stomach-pump or, when this is not attainable, by the more active mechanical emetics, such as mustard flour, zinc sulphate, or copper sulphate, conjoined with ipecacuanha. Emetics are uncertain in their action, but preferable to the stomach-pump when opium has been swallowed in substance; as the lumen of the tube may be insufficient to permit the passage of the masses in which the poison is sometimes taken. The operation of the emetic should be promoted by a very free use of warm drinks, by irritating the fauces with a feather, by keeping the patient in motion, and, if the insusceptibility to the action of the remedy is very great, by dashing cold water upon the head and shoulders. Very frequently, before the practitioner has reached the patient the narcotism will have progressed so far that it is impossible to cause vomiting at once. Owing to the great disturbance of respiration, two poisons are circulating in the blood, namely, opium and accumulated carbonic acid gas. By arousing the patient, and forcing him to supplement the disabled involuntary breathing by voluntary efforts, or, in extreme cases, by artificial respiration, the blood may be so far purified that the nervous centres recover sufficiently their sensitiveness to enable the emetic to act. The great cause of death is failure of respiration; and the keeping the patient awake, and the procedures already spoken of, are for the purpose of preventing this failure. Peremptory orders to breathe should be continually shouted in the ear of the patient. Shaking, forcing to walk, and the galvanic brush, or even flagellations, should be made use of to get the rousing effects of action and pain. Atropine, strychnine, and cocaine should always be used by hypodermic injection as respiratory stimulants. The dose of the alkaloids depends upon the amount of the poison swallowed. It is best to commence with from $\frac{1}{20}$ to $\frac{1}{70}$ of a grain of atropine, and repeat as often as necessary. As an adjuvant to the atropine, strychnine (gr. $\frac{1}{30}$) and cocaine (gr. $\frac{1}{6}$) may be given hypodermically with great advantage repeated *pro re nata*. The chief guide is the action upon the respiration, though the influence upon the pupil and circulation should always be considered. The desired effect is the maintenance of the respiration at or near the normal rate. When cardiac debility comes on, ammonia in some form may be employed; also alcohol, but not in too large quantities, for fear of deepening the narcosis; whilst tincture of digitalis should be administered hypodermically. Coffee has been found to be of service in producing wakefulness. It should be given *ad libitum*, and as strong as it can be made, or the alkaloid caffeine may be used in five-grain doses repeated *pro re nata*. In some rare cases, bleeding, in the early stages of opium poisoning, when evidences of brain congestion have been very pronounced, has been of distinct advantage. When other measures fail, artificial respiration, and especially forced artificial respiration, should always be resorted to. It is to be kept up until the heart-beats have certainly ceased.

OPIUM DEODORATUM. U. S. Deodorized Opium.

(Ō'PĮ-ŭM DĒ-Ō-DŌ-RĀ'TŬM.)

Opium Denarcotisatum, *U. S.* 1880; Denarcotized Opium.

"Powdered Opium, containing 13 to 15 per cent. of morphine, *one hundred grammes* [or 3 ounces av., 231 grains]; Ether, *fourteen hundred cubic centimeters* [or 47 fluidounces, 163 minims]; Sugar of Milk, recently dried and in fine powder, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 231 grains]. Macerate the Powdered Opium with *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of Ether, in a well-closed flask, during twenty-four hours, agitating from time to time. Pour off the clear, ethereal solution as far as possible, and repeat the maceration with two further portions of Ether, each of *three hundred and fifty*

cubic centimeters [or 11 fluidounces, 400 minims], first for twelve hours, and the last time for two hours. Collect the residue in a weighed dish, dry it, first by a gentle heat, and finally at a temperature not exceeding 85° C. (185° F.), and mix it thoroughly, by trituration, with enough Sugar of Milk to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]." *U. S.*

This preparation represents the medicinal properties of opium without the presence of the narcotic and odorous principles, which are believed by many physicians to play an important part in the nausea and depression produced in some people by opium. As the original weight of the opium is restored at the end of the process by the addition of sugar of milk, the dose is the same as that of the powdered opium.

OXYMEL. Br. Oxymel.

(ŏX'Y-MĔL.)

Oxymel Simplex, *P. G.;* Mel Acetatum, Oxymellite simple, Acétomel, *Fr.;* Sauerhonig, *G.*

"Clarified Honey, liquefied, 40 *ounces* (Imperial) or 800 grammes; Acetic Acid, 5 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Distilled Water, *a sufficient quantity.* Mix the Clarified Honey with the Acetic Acid and about *five fluid ounces* (Imp. meas.) or one hundred cubic centimetres of Distilled Water, or sufficient to produce Oxymel having the specific gravity 1·320." *Br.*

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines and to impart flavor to drinks in febrile complaints. Dose, from one to two fluidrachms (3·9–7·5 C.c.).

OXYMEL SCILLÆ. Br. Oxymel of Squill.

(ŏX'Y-MĔL SQĬL'LÆ—sĭl'lē.)

"Squill, bruised, 2½ *ounces* (Imperial) or 75 grammes; Acetic Acid, 2½ *fl. ounces* (Imp. meas.) or 75 cubic centimetres; Distilled Water, 8 *fl. ounces* (Imp. meas.) or 240 cubic centimetres; Clarified Honey, liquefied, *a sufficient quantity.* Digest the Squill for seven days in a mixture of the Acetic Acid and Distilled Water. Press strongly; filter. Mix the product, which should measure approximately *ten fluid ounces* (Imp. meas.) or three hundred cubic centimetres, with about *twenty-seven fluid ounces* (Imp. meas.) or eight hundred and ten cubic centimetres of the Clarified Honey, or sufficient to produce Oxymel of Squill having the specific gravity 1·320." *Br.*

After a long vogue, this preparation fell into such neglect that it was abandoned by the Pharmacopœias. Its reintroduction, however, into the Br. Pharmacopœia indicates that it is still prescribed. It has the virtues of squill, but is in no respect superior to the syrup. It is chiefly used as an expectorant in *chronic catarrh, humoral asthma, whooping-cough,* and generally in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucus of difficult expectoration. The dose is from one to two fluidrachms (3·9–7·5 C.c.). In large doses it is emetic, and as such is sometimes used in *infantile croup.*

PANCREATINUM. U. S. Pancreatin.

(PĂN-CRĒ-Ą-TĪ'NŬM.)

"A mixture of the enzymes naturally existing in the pancreas of warm-blooded animals, usually obtained from the fresh pancreas of the hog (Sus scrofa, Linné; class, Mammalia; order, Pachydermata)." *U. S.*

The term "pancreatin" has been variously used for many different preparations from the pancreatic gland, and has long been popularly employed for the purpose of distinguishing preparations more or less of the nature of extracts made from the gland. The *pancreatic juice* is an albuminous, transparent liquid, odorless, alkaline, and containing about eight per cent. of organic matter. It is now generally recognized that there are present in it three or, perhaps, four different ferments: *trypsin,* whose function it is, when in alkaline solution, to convert albuminous bodies into peptones; *amylopsin,* a diastatic ferment, closely allied to, if it be not identical with, the ptyalin of the saliva, and possessed of the power to convert raw or boiled starch into sugar (chiefly maltose); *steapsin,* which has the power of splitting up fats into glycerin and fatty acids; and a *peculiar substance,* not very well known, which acts as a coagulant of milk. Besides its digestive properties the pancreatic juice has the power of emulsifying fats. This emulsifying property is possessed by an alkaline aqueous infusion of the gland, and is therefore present in properly prepared pancreatic extracts. It is independent of any of the ferments, and is probably dependent on the presence of a peculiar form of casein or albumin. Rachford's

experiments appear to prove that pancreatic juice in the presence of an equal quantity of bile and 0·25 per cent. of hydrochloric acid developed its highest efficiency. (*Journ. Chem. Soc.*, 1891, 948.)

The pancreatin of the U. S. Pharmacopœia is composed of all these ferments, with more or less extraneous matter. It is officially described as "a yellowish, yellowish-white, or grayish, amorphous powder, odorless, or having a faint, peculiar, not unpleasant odor, and a somewhat meat-like taste. Slowly and almost completely soluble in water, insoluble in alcohol. Pancreatin digests albuminoids, and converts starch into sugar; prolonged contact with mineral acids renders it inert. If there be added to 100 C.c. of tepid water contained in a flask, 0·28 Gm. of Pancreatin and 1·5 Gm. of sodium bicarbonate, and afterwards 400 C.c. of fresh cow's milk previously heated to 38° C. (100·4° F.), and if this mixture be maintained at the same temperature for thirty minutes, the milk should be so completely peptonized, that, if a small portion of it be transferred to a test-tube and mixed with some nitric acid, no coagulation should occur. Peptonized milk, prepared in the manner just described, or even when the process is allowed to go on to the development of a very distinct, bitter flavor, should not have an odor suggestive of rancidity." *U. S.* R. H. Jones found commercial pancreatin unable to withstand the U. S. P. tests, which he states are too stringent; he suggests the addition of a starch digestion test. (*P. J. Tr.*, 1896, 194.)

Pancreatin extracts are prepared by different processes by several manufacturers. The process described by R. V. Mattison, based on the method of Scheffer for obtaining pepsin, is as follows. Macerate the cut-up pancreas in water acidulated with hydrochloric acid for forty-eight hours; filter till clear. Add a saturated solution of sodium chloride, and allow to stand until pancreatin rises to the top; skim this, drain on a muslin filter, wash with a less concentrated solution of salt, and press until nearly dry; then rub up with sugar of milk, dry thoroughly, without heat, and dilute with sugar of milk until ten grains just emulsify two drachms of cod-liver oil. The mixed pancreatic enzymes may be extracted from the gland by means of glycerin, and such an extract may be preserved indefinitely. A useful and permanent extract may also be obtained by exhausting the finely divided pancreas with water containing about 2 per cent. of boric acid and 1 per cent. of borax. (Allen, *Com. Org. Anal.*, 2d ed., vol. iv. 354.) As the power of pancreatin cannot be judged of accurately by its physical appearance, it is very important to have some test which will rigidly decide as to its value. If pancreatin be added to fresh milk without an alkali, in the course of a few minutes the liquid acquires the property of curdling abundantly upon boiling; and Dr. Wm. Roberts (*Digestive Ferments*, London, 1881) estimates the value of a pancreatin by the number of cubic centimetres of milk which are transformed by one cubic centimetre of the sample at a temperature of 40° C. to the curdling point in five minutes. (See *Liquor Pancreatis*, p. 813.)

Medical Properties and Uses. Pancreatin was first used in medicine on account of its emulsifying properties. Dr. Horace Dobell, noticing that consumptives are very apt to have a dislike for fat, conceived the idea that this was due to lack of pancreatic digestion, and administered an emulsion made with the fat of beef stirred in milk with the pancreatic juice of the pig. A little later, pancreatic preparations of cod-liver oil were prepared, and still have much vogue. Besides this employment, pancreatin has two distinct uses: first, as a ferment to be administered in dyspepsia; second, as a valuable means for the pre-digestion of food. As pancreatin acts in an alkaline solution and pepsin in an acid one, it would seem *a priori* not probable that pancreatin given by the stomach would be of avail in cases of feeble digestion. At present, however, we have not the knowledge to enable us to reach any definite conclusion in this regard.* In the pre-digestion of food by pancreatin, five grains of commercial pancreatin of good quality, with twenty grains of sodium bicarbonate, in an ounce of warm water, may be added to a pint of milk and kept at the temperature of 110° F. for an hour. As the thoroughly peptonized or pre-digested food is very bitter, when the milk is to be given by the mouth it is better to arrest the peptonizing process by boiling the milk after digestion has continued for twenty to thirty minutes, unless the milk can be used at once. For receipts for preparing various peptonized foods, see H. C. Wood's *Therapeutics*. Nutritive enema should be thoroughly pancreatized.

* In this respect the research of Mr. J. Schweitzer (*P. J. Tr.*, 1887) is interesting: he states that: 1. Pancreatin and pepsin both act with perfect ease in the presence of each other. 2. When digested together they do not destroy each other, nor do they lessen each other's digestive activity in whatever proportion they may be digested. 3. Long-continued exposure to heat and moisture injures their original activity. 4. Digested in alkaline or acid solutions, the injury is increased. 5. Pancreatin when digested for some hours in acid solution becomes permanently injured or destroyed. 6. Pepsin when digested in an alkaline solution for some hours is also permanently destroyed. (See, also, M. Gross, *Apoth. Ztg.*, 1887.)

PAPAVERIS CAPSULÆ. Br. Poppy Capsules.

(PA-PĀ'VE-RĬS CĂP'SŬ-LÆ.)

"The nearly ripe dried fruits of Papaver Somniferum, Linn." *Br.*

Papaver, *U. S.*, 1870; Fructus s. Capita Papaveris, *P. G.;* Capsules (Têtes) de Pavots, *Fr.;* Kapseln des Weissen Mohns, Mohnkapseln, Mohnköpfe, *G.;* Capidel Papavero, *It.;* Cabezas de Amapola, *Sp.*

In England the poppy is cultivated chiefly for its capsules, which are gathered as they ripen, and taken to market enclosed in bags. The Br. Pharmacopœia directs them to be collected before they are quite ripe, as they then contain more of the active milky juice; but, cut at this period, they are apt to lose their juice through the wounded surface, unless carefully kept inverted upon their crown while drying; and, even when thus treated, they are, according to the observations of Buchner, less active than the capsules collected after perfect maturity, while they contain more of useless saccharine and mucilaginous matter. (*Buchner's Repert.*, 3 R., viii. 289 and 326.) M. Meurein states, as the result of his experiments, that the richest are those collected just before the maturity of the seeds, when the capsules have passed from their glaucous green to a yellowish-green color. (*Journ. de Pharm.*, 3e sér., xxiii. 341.) They are occasionally imported; but, as no effect is produced by them which cannot be as well obtained from opium, they are little employed.

Dried *poppy capsules* vary in size from the dimensions of a small egg to those of the fist. They differ also in shape according to the variety of the poppy from which they are procured. On the Continent two sub-varieties of the white poppy are recognized, the *long*, and the *round* or *depressed*. Of these, according to Aubergier, the long are richest in morphine, and his conclusions are confirmed by Meurein, who also found the largest capsules most efficient. Those commonly found in commerce are spheroidal, flattened below, and surmounted by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above its upper surface and appear to be prolongations of partial septa, or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. In the recent state, the seeds, which are very numerous, adhere to these septa; but in the dried capsule they are loose in its cavity. The capsules of the black poppy are smaller and more globular than those of the white, and contain dark instead of light-colored seeds. There appears to be no essential difference in their properties. Both kinds, when fresh, are glaucous, but when dried are of a dirty-white or purplish-brown color, of a consistence somewhat like that of paper, inodorous, and with little taste, unless long chewed, when they are decidedly bitter. They contain principles, in very small quantities, similar to those of opium, which they yield to water by decoction, and have been employed in France for obtaining morphine.

On the continent of Europe, the poppy is cultivated largely for its seeds, which yield about fifty per cent. of an excellent fixed oil on expression. *Poppy-seed oil* is of a pale golden color, liquid at 5·5° C. (42° F.), easily dried, inodorous, and of a pleasant flavor. It is bleached by exposure in thin layers to the sun. (*P. J. Tr.*, March, 1874, p. 731.) For chemical composition, see *Opium*, page 986.

Medical Properties and Uses. Dried poppy-heads, though analogous to opium in medicinal properties, are exceedingly feeble. They are nevertheless asserted to have proved fatal, in the form of decoction, to a child. The case, reported by Dr. F. L. Winckler, was that of a babe, in the stomach of which he found a little morphine, but no meconic acid. (*Neues Repert.*, 1867, xvi. 38.) They are sometimes employed in decoction, as an external emollient and anodyne application, and, in emulsion, syrup, or extract, are often used internally, in Europe, to calm irritation, promote rest, and produce generally the narcotic effects of opium.

PARAFFINUM DURUM. Br. Hard Paraffin. [Paraffin. Paraffin Wax. Solid Paraffin.]

(PĂR-ĄF-FĪ'NŬM DŪ'RŬM.)

"A mixture of several of the harder members of the paraffin series of hydrocarbons; usually obtained by distillation from shale, separation of the liquid oils by refrigeration, and purification of the solid product." *Br.*

The name paraffin, often spelled *paraffine*, was originally bestowed by Baron von Reichenbach upon a waxy substance obtained through the destructive distillation of wood. He derived it from *parum affinis*, and thus intended to indicate its very neutral character. The name is now popularly applied to a solid white diaphanous substance, resembling white wax, which is procured from petroleum or bituminous shales by distillation, or from ozokerite by purification. (See *Ozokerite*, *Ceresin*, in PART II.) In the manufacture from petroleum, as carried out in

the United States, the residuum from the distillation of crude petroleum for illuminating oil is taken. This is redistilled from what are called "tar-stills," in which the distillation is pushed until only coke remains. The paraffin oil distillate is treated with from 4 to 5 per cent. of sulphuric acid, washed, and treated with caustic soda, the mixture being kept liquid by the aid of steam coils. After settling, the paraffin oil goes to the "chill-rooms," where, by the aid of the ammonia refrigerating machines and the circulation of cooled brine, the whole mass is brought to a semi-solid condition. This is subjected to powerful pressure, and the refined heavy oil which drains off is collected as lubricating oil. Its specific gravity should be about 32° B. The press-cake may be broken up, melted, and allowed to solidify, and then submitted to still greater pressure at a higher temperature (70° F.) than before, when the product is known as "refined wax." To convert it into block paraffin it must be washed with benzin, pressed, melted, and filtered through bone-black or other medium, when it solidifies in a hard, translucent, colorless block.

Properties. Paraffin, in its pure condition, is a white, waxy, inodorous, tasteless substance, harder than tallow, softer than wax, with a specific gravity of 0·877. Its melting point is variable, depending somewhat upon its origin. It ranges between 43° and 65° C. (109° and 151° F.). An ultimate analysis yields, on the average, carbon 85 per cent. and hydrogen 15 per cent. It is insoluble in water, is indifferent to the most powerful acids, alkalies, and chlorine, and can be distilled unchanged with strong oil of vitriol. Warm alcohol, ether, oil of turpentine, olive oil, benzene, chloroform, and carbon disulphide dissolve it readily. It can be mixed in all proportions with wax, stearin, palmitin, and resin. As stearin is less soluble in benzene than paraffin, Vogel proposes this reaction as a method for detecting the adulteration of paraffin with stearin. (Joy.) The Br. Pharm. describes it as "colorless, semi-transparent, crystalline, inodorous and tasteless, slightly greasy to the touch. Specific gravity 0·82 to 0·94. Insoluble in water, slightly soluble in absolute alcohol, almost entirely soluble in ether. An alcoholic solution should not redden litmus. It melts at 130° to 135° F. (54·4° to 57·2° C.), and burns with a bright flame, leaving no residue." The fact that solid paraffin wax is essentially made up of a mixture of hydrocarbons of the series C_nH_{2n+2} was established by Gill and Mensel, who studied the action of bromine upon it. The fact that when paraffin wax is oxidized by concentrated nitric acid or by chromic acid mixture we obtain *paraffinic acid*, $C_{24}H_{48}O_2$, and *cerotic acid*, $C_{27}H_{54}O_2$, shows that it is essentially made up of hydrocarbons between $C_{24}H_{50}$ and $C_{27}H_{56}$. For *Soft Paraffin*, or *Paraffinum Molle*, see *Petrolatum*, p. 1016.

It would be beyond the scope of this work to give all the uses of this very valuable substance. The largest quantity is consumed in candles. It is said that meat may be preserved by immersing it in melted paraffin. Lemons may also be kept in this way. It is used to coat paper to make it impervious to moisture, as a lubricator, for adulterating chocolate and candies, in large quantities as a basis for chewing gum, to coat pills, etc. (*A. J. P.*, 1895, 422.)

PARALDEHYDUM. U. S., Br. Paraldehyde.

$C_6H_{12}O_3$; 131·7. (PA-RĂL-DĒ-HĪ'DŬM.)

"A polymeric form of Ethylic Aldehyde [$C_2H_4O = 43·9$]. Paraldehyde should be kept in well-stoppered, dark amber-colored bottles, in a cool place." *U. S.* "Paraldehyde, $C_6H_{12}O_3$, is a product of the polymerization of aldehyde by various acids and salts." *Br.* Small quantities of acids like hydrochloric and sulphuric, and of certain salts like zinc chloride, $ZnCl_2$, convert aldehyde at ordinary temperatures into its polymer paraldehyde. Its properties are thus described officially: "A colorless, transparent liquid, having a strong, characteristic, but not unpleasant or pungent odor, and a burning and cooling taste. Soluble in 8·5 parts of water at 15° C. (59° F.), and in 16·5 parts of boiling water; miscible, in all proportions, with alcohol, ether, and fixed or volatile oils. When cooled to near 0° C. (32° F.), Paraldehyde solidifies to a crystalline mass, which becomes liquid again at 10·5° C. (51° F.). It boils at 123°–125° C. (253·4°–257° F.), giving off inflammable vapors. Paraldehyde is neutral, or slightly acid, to litmus paper. When distilled with a small portion of sulphuric acid, Paraldehyde is converted into ordinary aldehyde, boiling at about 21° C. (70° F.). On warming some silver ammonium nitrate test-solution saturated with Paraldehyde, in a test-tube, a silver mirror will form on standing. On heating some Paraldehyde on a water-bath, it should completely volatilize, without leaving any disagreeable odor (absence of *aldehyde derived from fusel oil*). One C.c. of Paraldehyde should form, with 10 C.c. of water, a clear solution, free from oily drops (absence of *amylic alcohol*, etc.), and this solution, when acidulated with nitric

acid, should not be affected by silver nitrate test-solution (absence of *hydrochloric acid*), or barium chloride test-solution (absence of *sulphuric acid*). A mixture of 8 C.c. of Paraldehyde and 8 C.c. of alcohol with 1 drop of phenolphtalein test-solution should acquire a pink color upon the addition of 0·5 C.c. of normal potassium hydrate test-solution (limit of *free acid*)." *U. S.*

The British Pharmacopœia gives the following properties and tests: "Soluble in 10 parts of *water* at 60° F. (15·5° C.); less soluble in hot *water*. Miscible, in all proportions, with *alcohol* (90 per cent.) and with *ether*. An aqueous solution should not affect *solution of litmus*. Specific gravity 0·998. Boiling point 255·2° F. (124° C.). It may be congealed to a clear crystalline mass which melts at about 50° F. (10° C.). It affords no coloration on standing for two hours mixed with *solution of potassium hydroxide* (absence of aldehyde), and should yield no characteristic reaction with the tests for sulphates or for chlorides."

Medical Properties and Uses. Paraldehyde produces in the frog and also in mammals sleep, with complete muscular relaxation and loss of sensibility. The heart is not affected until late in the poisoning, and death results from paralysis of the respiratory centre. Not only the brain but also the whole lower nervous system is influenced by the toxic dose of paraldehyde, which decreases the functional activity of the spinal cord, of the motor and sensory nerve-trunks, and even of the muscles. It is eliminated by the urine, to which it imparts its odor, and according to Gordon it increases the excretion of urea. Quinquaud affirms that under its toxic action methæmoglobin appears in the blood. In practical medicine it has been found a safe but somewhat uncertain hypnotic, whose use is greatly limited by its having no influence over pain, by its nauseous taste, and by its tendency to disturb the stomach. Dr. J. G. Kiernan has found the prolonged use of paraldehyde to be followed by the same intractable nasal ulcers, skin eruptions, and other evidences of disturbance of nutrition that are seen after the similar employment of chloral. It must always be given well diluted, in doses of from half a fluidrachm to a fluidrachm and a half (1·8 to 5·5 C.c.).

PAREIRA. U. S. (Br.) Pareira. [Pareira Brava.]

(PA-REI'RA—pę-rā'rą.)

"The root of Chondodendron tomentosum, Ruiz et Pavon (nat. ord. Menispermaceæ.)" *U. S.* "The dried root of Chondrodendron tomentosum." *Br.**

Pareiræ Radix, *Br.;* Pareira Root; Pareira Brava, *Fr., G.*

Under the name of Pareira Brava there are three distinct drugs met with in our market. Of these the rarest is the product of the *Cissampelos pareira*. Messrs. Allen and Hanburys obtained from Jamaica a considerable quantity of this drug, the bulk of it composed of stems, which are described as being cylindrical, varying from the thickness of a quill to that of the forefinger, with a light-brown bark. The roots which we have met in American commerce are rarely more than three-fourths of an inch in diameter, are much contorted, and irregularly cylindrical, with a dark-brown exterior, which is longitudinally much wrinkled or furrowed. On section they are seen to be composed of a thick corky bark enclosing a woody cylinder consisting of a number (10 to 20) of convergent vascular bundles, separated by wedge-shaped, very porous, medullary rays. There are no concentric layers of wood. (See cut.) The color is a light yellowish fawn tint, the taste a pure bitter. This is the Pareira Brava of the Br. Pharmacopœia of 1870, the present Br. Pharmacopœia agreeing with the U. S. Pharmacopœia in recognizing the root of *Chondodendron tomentosum*.

Cissampelos pareira, transverse section. (Slightly magnified.)

The ordinary pareira brava of our markets is that which was exhibited at Philadelphia in the Centennial Exhibition of 1876 by the Brazilian government as the product of *Cissampelos*

* A *West African False Pareira brava* which has appeared in the London markets is of a chocolate-brown color externally, and of a yellow and brownish-yellow internally. Its woody zones are numerous, and in the larger pieces are arranged eccentrically. The root-portions have a star of small size in the centre with a variable number of straight rays. The woody wedges are narrow, and their vessels, seen by the microscope, small in diameter. For an elaborate description of the finer microscopical characters of this root as contrasted with that of the Chondodendron, see *P. J. Tr.*, 17, 218.

pareira, but which is now recognized as being obtained from *Chondodendron tomentosum*. It consists of great pieces of roots, some of them four inches in diameter and three feet long. They are irregularly cylindrical, often somewhat four-sided, with a thin, brownish, closely adherent bark, often grayish in color, and not so closely wrinkled as in the true pareira brava. On section the root is seen to consist of from three to nine concentric or eccentric rings of growth of a breadth of from one-eighth to one-third of an inch. There is not a distinct continuous series of medullary rays, but each zone is composed of wedge-shaped masses, formed of divergent lines of dense woody tissue arched exteriorly over the porous parenchyma. The stems have a similar structure, but with an obvious pith. (See cut.) This is the Pareira Brava of the present U. S. Pharm., which describes it as follows. "In subcylindrical, somewhat tortuous pieces, about 10 to 15 Cm. long, varying in thickness from 2 to 10 Cm.; externally dark brownish-gray, with transverse ridges and fissures and longitudinal furrows; internally pale brown, and, when freshly cut, having a waxy lustre; bark thin; wood porous, in two or more somewhat irregularly concentric circles, with rather large medullary rays, and no distinct central pith; inodorous; taste bitter. Pieces having a bright yellow color, or the woody portion of which is grayish, hard, and nearly tasteless, should be rejected." *U. S.*

Chondodendron tomentosum, transverse section. (Natural size.)

Under the name of *Common False Pareira*, Flückiger and Hanbury describe a drug which they state to be a common drug of the Brazilian and English markets. "It consists of a ponderous, woody, tortuous stem and root, occurring in pieces from a few inches to a foot or more in length, and from 1 to 4 inches in thickness, coated with a thin, hard, dark-brown bark. The pieces are cylindrical, four-sided, or more or less flattened,—sometimes even to the extent of becoming ribbon-like. The stem differs from the root externally in being less tortuously and more sparingly marked with transverse ridges and constrictions or cracks, also in the longitudinal furrows being more regular. In transverse section of the stem a well-defined pith will be found to occupy the centre of the first-formed wood, which is a column about ¼ of an inch in diameter. This is succeeded by 10 to 15 or more concentric or oftener eccentric zones, $\frac{1}{10}$ to $\frac{2}{10}$ of an inch wide, each separated from its neighbor by a layer of parenchyme, the outermost being coated with a true bark. In pieces of *true root*, the pith is reduced to a mere point." (*Pharmacographia*, p. 29.) This false pareira is not often seen in America. It is stated that in it Wiggers discovered pelosine in 1839. Its botanical source is unknown, but is believed to be a Menispermum.*

Chondodendron tomentosum. Ruiz and Pavon.—*Cocculus chondodendron*. De C.—*Botryopsis platyphylla*. Miers. This is a climbing, woody vine, which attains often a considerable height, and is remarkable for the size of its leaves. These are about a foot long, broadly ovate or rounded, slightly cordate, with a smooth upper surface, and on the under surface, between the

* *White Pareira Brava*, the stems and root of *Abuta rufescens*, is described by Flückiger and Hanbury as consisting "of short pieces of a root half an inch to three inches thick, covered with a rough blackish bark, and also of bits of stem having a pale, striated, corky bark cut transversely. The root displays a series of concentric zones of white amylaceous cellular tissue, each marked with narrow wedge-shaped medullary rays of dark porous tissue."

Yellow Pareira Brava is described as consisting "of portions of a hard, woody stem, from one to six inches in diameter, covered with a whitish bark. Internally it is marked by numerous regular concentric zones, is of a bright-yellow color and a bitter taste." It contains beberine.

The root of *Cocculus Cæba*, G. P. et Rich., a native of Northern India, Afghanistan, and Arabia, according to Heckel and Schlagdenhauffen, resembles in appearance and medical properties Pareira brava, and contains about 2 per cent. of pelosine with 3 per cent. of a new alkaloid, *sangoline*. This melts at 188° F., and in alcoholic or chloroformic solution rotates the plane of polarized light to the right. It is thrown down by water from its alcoholic solution, and does not give the color-reaction that is obtainable from pelosine with sulphuric acid and an oxidizing agent. The root also contains columbin, and is used in India as a substitute for hops in brewing.

veins, covered with a fine close wool of an ashy hue. The racemose fruits are of the size of large grapes, oval and black. This plant inhabits both Brazil and Peru.

Cissampelos pareira. Willd. *Sp. Plant.* iv. 861 ; Woodv. *Med. Bot.* 3d ed., p. 167, t. 65. This is a climbing plant, with numerous slender, shrubby stems, and roundish, entire leaves, indented at the top, covered with soft hair upon their under surface, and supported upon downy footstalks, inserted into the back of the leaf. The flowers are very small, and disposed in racemes, of which those in the female plant are longer than the leaves. The plant is a native of the West Indies and South America. According to Auguste St.-Hilaire, true pareira is obtained from another species of the same genus, growing in Brazil, *C. glaberrima.**

Properties. The root imparts its virtues readily to water. M. Feneulle found in it a soft resin, a yellow bitter principle, a brown substance, a nitrogenous substance, fecula, acid calcium malate, potassium nitrate, and various other salts. He considers the yellow bitter substance as the active principle. It is soluble in water and alcohol, and precipitated from its solution by tincture of galls. Wiggers announced in 1838 the existence in pareira brava of an alkaloid, for which he proposed the name of *pelosine* or *cissampeline*. He procured it by boiling the root with water acidulated with sulphuric acid, precipitating by potassium carbonate, dissolving the precipitate again in water acidulated with sulphuric acid, treating the solution with animal charcoal, precipitating anew with potassium carbonate, drying and pulverizing the precipitate, treating it repeatedly with ether, and evaporating the ethereal solution. The alkaloid thus obtained may be rendered entirely pure by dissolving it in diluted acetic acid, precipitating with potassium carbonate, and washing and drying the precipitate. (*Annal. der Pharm.*, xxvii. 29.) It is probably the chief ingredient of the bitter substance obtained by Feneulle. Peretti of Rome, and Pelletier afterwards, separated from the root an alkaloid characterized by assuming a beautiful purple color upon contact with strong nitric acid. (*Journ. de Pharm.*, xxvi. 162.) In Christison's Dispensatory it is stated to be uncrystallizable, insoluble in water, soluble in ether, alcohol, and the acids, and of an intensely bitter and sweetish taste. Flückiger (*P. J. Tr.*, 1870, p. 192) has found an alkaloid in the root, and, having thoroughly determined its origin, investigated its properties, and fixed its composition at $C_{18}H_{21}NO_3$, shows its identity with the *beberine* of nectandra and the *buxine* of *Buxus sempervirens* obtained by Walz. Ringer and Brooke (*A. J. P.*, 1892, 255) proved that the true chondodendron root contained a larger quantity of chemical and extractive principles than do the substitutes. (See also A. R. L. Dohme's paper, *Drug. Circ.*, 1896, 296.)

Medical Properties and Uses. Pareira brava is said to be tonic, aperient, and diuretic. It was introduced into European practice so long ago as 1688, and at one time enjoyed considerable reputation as a lithontriptic. It has been recommended in *calculous affections*, *chronic inflammation* and *ulceration of the kidneys and bladder*, *leucorrhœa*, *dropsy*, *rheumatism*, and *jaundice*. It is at present chiefly employed for the relief of *chronic inflammations of the urinary passages*, in which it was originally found by Sir Benjamin Brodie to be very useful. Advantage may often be derived from combining it with belladonna or hyoscyamus. In Brazil it is used in the cure of the *bites of poisonous serpents*,—a vinous infusion of the root being taken internally, while the bruised leaves of the plant are applied to the wound. The dose of pareira brava in substance is from thirty grains to a drachm (1·95–3·9 Gm.). The infusion, however, is more convenient. (See *Infusum Pareiræ.*) A tincture, made by macerating one part of the root in five parts of alcohol, has been given in the dose of a fluidrachm (3·7 C.c.). The aqueous extract may be given in the dose of from ten to thirty grains (0·65–1·95 Gm.). There is now an official fluid extract, of which the dose is from half a fluidrachm to a fluidrachm (1·9–3·7 C.c.).

PEPO. U. S. Pumpkin Seed.

(PĒ'PŌ.)

"The seed of Cucurbita Pepo, Linné (nat. ord. Cucurbitaceæ)." *U. S.*

Semences de Potirons, *Fr.;* Kürbissamen, *G.*

The *Cucurbita pepo*, or *common pumpkin*, is a plant too well known to need description. The seeds are the part used. These are oval, extended into a blunt point at one end, flattish but somewhat swollen in the middle, with a distinct groove on both sides near the edge from one

* *Pareira Bark.* Though the root is the official part, the bark is probably possessed of similar virtues. A specimen at the International Exhibition at London in 1862 was in flat pieces, from two to four inches broad, about a line thick, extremely fibrous, so tough that it could be bent without breaking, of a very light dirty-yellowish color, and covered with a light-colored epidermis.

end to the other, when of full size about 9 lines long by 5 or 6 in breadth where broadest, of a light brownish-white color, and a slightly sweetish, somewhat aromatic smell and taste. They consist of a firm brittle coating and a white oily kernel, composed of a short, conical radicle and two flat cotyledons, and contain a fixed oil, consisting of the glycerides of palmitic, myristic, and oleic acids, with some free fatty acids, an aromatic principle, chlorophyll, sugar, starch, and, according to Dorner and Wolkowich, an alkaloid, *cucurbitine*. Deprived of their coating, and exhausted by ether, they yield 30 per cent. of fixed oil. (*Annuaire de Thérap.*, 1862, p. 176.) The researches of Dorner and Wolkowich have not received confirmation, and their alkaloid probably has no existence. Pumpkin seed oil has a sp. gr. at 15° C. of 9·23, and solidifies at —15° C. The cold drawn oil is used for culinary purposes and the lower qualities for burning. The oil dries very slowly. (Lewkowitsch, *Chem. Analysis of Oils*. etc., 2d ed., 1898, 372.) Sieker obtained 30 per cent. of the oil from the seeds; it was reddish yellow in color, soluble in ether, benzol, and carbon disulphide, but insoluble in alcohol. (*Proc. A. P. A.*, 1897, 545.) Mr. J. C. Lyons used an ounce of it with success in a case of tapeworm (*A. J. P.*, 1865, 253), but Dr. Wolff has found it inert when pure and free from resin.* Heckel was the first to assert that the active principle is a resin, and in this he has been corroborated by Dr. L. Wolff (pamphlet, Phila., 1882), who has found the resin to be efficient in doses of fifteen grains (1 Gm.), given in pill, followed in two or three hours by castor oil, and who recommends an alcoholic fluid extract as the best preparation of the drug after the resin.† W. E. Miller (*A. J. P.*, 1891, 585) analyzed both the shells and the kernels of pumpkin seed. He also found a resin soluble in alcohol, and a dark reddish fixed oil.

Medical Properties. It is said that in Italy the seeds of the *Cucurbita maxima*, and in the West Indies those of *C. occidentalis*, have been long used in doses of an ounce and a half as tænifuges. In the *Dictionary of Materia Medica* by Mérat and De Lens (ii. 493) it is stated that Dr. Hoarau had reported that in the Isle of France the seeds of a small variety of pumpkin were used against the *tape-worm*, and with never-failing success. In the year 1820, M. Mongeney, a physician of Cuba, published the results of his experience with the flesh of the pumpkin in the same disease. He had discovered the remedy by accident, and found it uniformly successful. He gave to the patient, in the morning, fasting, about three ounces of the fresh pumpkin in the form of a paste, and followed it at the end of an hour by about two ounces of honey, which latter was twice repeated at intervals of an hour. So far as we know, attention was first directed to it in this country by Mr. Richard Soule. (*Bost. Med. and Surg. Journ.*, Oct. 1851.) Since this time the drug has steadily grown in favor, and, properly used, is one of our most efficient and harmless tænifuges. The patient should be allowed only a light supper of bread and milk, in the morning early should take an ounce and a half of the seeds, a cup of tea or coffee an hour later, but no food, at 10 A.M. a brisk cathartic, and two hours later a substantial meal. We have obtained excellent results from the exhibition of the beaten seeds in the form of an electuary strongly flavored with oil of cinnamon or of gaultheria.

PEPSINUM. U. S. (Br.) Pepsin.

(PĔP-SĪ'NUM.)

"A proteolytic ferment or enzyme obtained from the glandular layer of fresh stomachs from healthy pigs, and capable of digesting not less than 3000 times its own weight of freshly coagulated and disintegrated egg albumen, when tested by the process given below. If it be desired to use a diluent for reducing Pepsin of a higher digestive power to that required by the Pharmacopœia, Sugar of Milk should be employed for this purpose." *U. S.* "An enzyme obtained from the mucous lining of the fresh and healthy stomach of the pig, sheep, or calf. Tested as described in the following paragraph [see p. 1014], it should dissolve 2500 times its weight of hard-boiled white of eggs." *Br.*

Pepsin, *Br.;* Pepsinum Saccharatum, *U. S.* 1880; Saccharated Pepsin; Pepsine, *Fr.;* Pepsin, *G.*

The U. S. P. 1890 recognizes two pepsins, one under the name "Pepsinum." the other "Pepsinum Saccharatum:" the first, or strong pepsin, should digest at least 3000 times its

* The following plan of Mr. Charles Hand has given great satisfaction in Camden, N.J. Take of the seed sixteen troyounces, alcohol of the sp. gr. 0·835 a sufficiency. Bruise the seed with an equal bulk of washed sand until thoroughly comminuted, transfer to a conical percolator, pour on the alcohol till three pints have passed; reserve the first twelve ounces of the percolate, reduce the remainder to four fluidounces by distillation; and, lastly, mix with the reserved liquor, and filter. (*A. J. P.*, 1869, p. 195.)

† He prepares it by extracting the oil from the powdered seeds by means of petroleum benzin, then treating the remaining powder with ether, chloroform, and alcohol, which yields on evaporation a soft greenish-brown resinous liquid resembling the oleoresin of male fern.

own weight of freshly coagulated albumen; the other is the first product diluted with enough sugar of milk to make it contain 10 per cent. of the strong pepsin.

The British Pharm. 1885 gave the following process for pepsin: it is that proposed by Prof. Beale, of London. "The stomach of one of these animals [pig, sheep, or calf] recently killed having been cut open and laid on a board with the inner surface upwards, any adhering portions of food, dirt, or other impurity are to be removed and the exposed surface slightly and rapidly washed with a little cold water; the cleansed mucous membrane is then to be scraped with a blunt knife or other suitable instrument, with some pressure, and the viscid pulp thus obtained is to be immediately spread over the surface of glass or glazed earthenware and quickly dried at a temperature not exceeding 100° F. (37°·8 C.). The dried residue is to be reduced to powder and preserved in a stoppered bottle." *Br.*

It is now clearly recognized that pepsin owes its digestive action to the presence of a ferment or enzyme, and, although many researches have been made to obtain the pure principle, the nearest approaches have resulted only in producing pepsins of increased digestive power. Pepsins having much greater digestive capacity than that chosen for the U. S. official standard have been manufactured, and the limit has not at this time (1899) been reached; but for all practical purposes the U. S. P. 1890 pepsin is sufficiently concentrated, and indeed it is usually diluted for internal administration.

Various attempts have been made to concentrate and bring to a convenient form for administration the peptic principle of the gastric juice. It must not be supposed that the substances prepared with this object and sold under the name of pepsin have any claim to be considered as the pure principle. The one which for a long time was the best in the market was prepared by M. Boudault* by a process which was afterwards essentially adopted in the French Codex.

The pepsin of the British Pharmacopœia is "A light yellowish-brown or white powder, or pale yellow translucent grains or scales, having a faint odor and a slightly saline taste free from any trace of putrescence, and liable to absorb moisture from the air. Moderately soluble in *water*, and soluble in about 100 parts of *alcohol* (90 per cent.)."

The U. S. Pharmacopœia recognized pepsin for the first time in the revision of 1880, but it had then been for some years largely used by the American profession. Much of the pepsin thus employed was obtained from Europe, and was of very various quality, most of it being heavily loaded with starch, and some of it containing little or no pepsin. Several American brands have, however, been put upon the market which are superior to Boudault's pepsin. Various processes also have been recommended for obtaining pepsin. The most elaborate and valuable investigation of the subject as yet made is that of Prof. E. Scheffer (*A. J. P.*, 1872). He found that various salts, such as sodium and magnesium sulphates and sodium chloride, precipitate pepsin, and, acting upon this discovery, he devised the following processes. Mucous membrane of the pig's stomach, dissected off and finely chopped, is macerated in water acidulated with hydrochloric acid for several days, with frequent stirring. The strained liquid, if not clear, is clarified by allowing it to stand for 24 hours and decanting. Sodium chloride is then thoroughly mixed with it. After several hours the floating pepsin is skimmed from the surface and put on a cotton cloth to drain, and finally submitted to strong pressure to get rid of saline solution. This pepsin, when air-dried, is very tough, parchment-like or leathery, varying in color from a dim straw-yellow to a brownish yellow. To make his *saccharated pepsin*, Prof. Scheffer adds sugar of milk until a powder is obtained of which 10 grains will dissolve 120 grains of coagulated albumen. Since his original process, he has increased the strength of saccharated pepsin. *Purified pepsin* he makes by redissolving the pepsin in acidulated water and precipitating as before, immersing the product when perfectly dry in pure water for a short time. A half-grain of this dissolved 1500 grains of albumen. (*Ibid.*, p. 784.) The chemical relations of pepsin are so delicate and wide-spread that it ought to be given by itself, or in combination only with an insoluble substance, or suspended in inert liquids.

Since Prof. Scheffer's researches were made known, pepsin has been manufactured in the United States in immense quantities,† the tendency having been towards strengthening and

* For the process for *Boudault's pepsin*, see *U. S. D.*, 17th ed., 1014.

† *Jensen's Pepsin.* This pepsin has had a large sale, and the following process is given by C. L. Jensen, which produces what he calls "crystal pepsin," and which he has patented. Mucous membranes, or the whole stomach, after being finely cut are introduced into a capacious stone jar or vessel and mixed with about one-fifth of water acidulated enough to possess the sourness of vinegar. The mixture is then heated gently from 100° to 130° Fahrenheit, and under constant agitation the stomachs are converted into a peptone of a syrupy consistence, which, after

purifying the product. Many other substances than sugar of milk have been used to mix with pepsin, as egg and blood albumen, fibrin, and substances which are easily converted into peptones. The process for making most commercial pepsins may be briefly stated as follows. The inner membranous linings of hogs' stomachs are washed, passed through a mincing machine, and the resulting mass digested with diluted hydrochloric acid; the solution is strained or filtered and evaporated *in vacuo* or placed on shallow trays so that a syrupy liquid which has not been subjected to a higher temperature than 112° F. is produced; this is spread upon glass plates to dry, and the scales which are formed scraped off. The thickness of the scales may be varied by using more or less concentrated solutions, and the proportion of peptone is increased by extending the length of time in the digestion process and raising the temperature to the utmost safe limit. Numerous pepsins of value are upon the market, and they are so readily tested that the practitioner need not be at a loss. (See *Proc. A. P. A.*, 1884, 1886, and 1890; *Pharm. Record*, 1893, 104; *West. Drug.*, 1887, 69; *Amer. Drug.*, 1885, 103; see also *Pancreatin* and *Pepsin* in National Formulary and PART II.)

Properties. Pepsin is "a fine, white, or yellowish-white, amorphous powder, or thin, pale yellow or yellowish, transparent or translucent grains or scales, free from any offensive odor, and having a mildly acidulous or slightly saline taste, usually followed by a suggestion of bitterness. It slowly attracts moisture when exposed to the air. Soluble, or for the most part soluble, in about 100 parts of water, with more or less opalescence; more soluble in water acidulated with hydrochloric acid; insoluble in alcohol, ether, or chloroform. On heating a solution of Pepsin in acidulated water to 100° C. (212° F.) it becomes milky, or yields a light, flocculent precipitate, and loses all proteolytic power. In a dry state it can bear this temperature without injury. Pepsin usually has a slightly acid reaction. It may be neutral, but should never be alkaline." *U. S.*

"**Valuation of Pepsin.**—Prepare, first, the following three solutions: *A*. To 294 C.c. of water add 6 C.c. of diluted hydrochloric acid. *B*. In 100 C.c. of solution *A* dissolve 0·067 Gm. of the Pepsin to be tested. *C*. To 95 C.c. of solution *A*, brought to a temperature of 40° C. (104° F.), add 5 C.c. of solution *B*. The resulting 100 C.c. of liquid will contain 2 C.c. of diluted hydrochloric acid, 0·00335 Gm. of the Pepsin to be tested, and 98 C.c. of water. Immerse and keep a fresh hen's-egg during fifteen minutes in boiling water; then remove it and place it into cold water. When it is cold, separate the white, coagulated albumen, and rub it through a clean sieve having 30 meshes to the linear inch. Reject the first portion passing through the sieve. Weigh off 10 Gm. of the second, cleaner portion, place it in a flask of the capacity of about 200 C.c., then add one-half of solution *C*, and shake well, so as to distribute the coherent albumen evenly throughout the liquid. Then add the second half of solution *C*, and shake again, guarding against loss. Place the flask in a water-bath, or thermostat, kept at a temperature of 38° to 40° C. (100·4° to 104° F.), for six hours, and shake it gently every fifteen minutes. At the expiration of this time the albumen should have disappeared, leaving at most only a few, thin, insoluble flakes. (Trustworthy results, particularly in comparative trials, will be obtained only if the temperature be strictly maintained between the prescribed limits, and if the contents of the flasks be agitated uniformly, and in equal intervals of time.) The relative proteolytic power of Pepsin stronger or weaker than that described above may be determined by ascertaining, through repeated trials, how much of solution *B* made up to 100 C.c. with solution *A* will be required exactly to dissolve 10 Gm. of coagulated and disintegrated albumen under the conditions given above." *U. S.* "If 12·5 grammes of coagulated and firm white of fresh eggs, 125 cubic centimetres of acidulated *water* containing about 0·2 per cent. of hydrogen chloride (HCl), and 0·005 gramme of Pepsin, be digested together at 105° F. (40·5° C.) for six hours, and shaken frequently, the coagulated white of eggs dissolves, leaving only a few small flakes, in an almost clear solution. The 'white of eggs' should be prepared by boiling quite fresh eggs in water for fifteen minutes, then immersing them in cold water, and, as soon as sufficiently cool for handling, separating the whites, washing off any fragments of yolk or membrane with water, removing the water with a clean towel, then at once rubbing the whites through a sieve having twelve meshes to a centimetre, and using the product before it has lost moisture. For the 'acidulated *water*' mix the official Hydrochloric Acid with *water* in the proportion of 1 gramme to 156 cubic

clarifying and purifying by any of the well-known methods, is spread on glass plates for drying in a room heated up to about 115° Fahrenheit. It is then scraped off, and the dry and brittle transparent flakes or scales are sifted through a sieve having about twenty linear threads to the inch, after which the product appears like minute scales. (*Pharm. Record*, 1883, 424.) This pepsin, as frequently found in the market, has an offensive odor.

centimetres; this will give a solution containing about 0·2 per cent. of hydrogen chloride (HCl)." *Br.*

In estimating the proteolytic power of pepsin by any method it is very important to adhere strictly to each requirement, otherwise great variations may be expected. (*Proc. A. P. A.*, 1893, 411, 722; 1894, 221; 1895, 244, 338; 1896, 260, 263; 1897, 745; *Amer. Drug.*, 1894, 212; 1895, 101; *Drug. Circ.*, 1896, 52.)

Three distinct types of pepsin are found in commerce: 1, pepsins insoluble in water without the addition of traces of acids; 2, pepsins soluble in water forming transparent solutions; 3, pepsins not entirely soluble in water or in diluted hydrochloric acid. The objection to the insoluble pepsins is, of course, the inconvenience resulting from their insolubility in water, but, on the other hand, they are more permanent, do not deteriorate so rapidly, and are active in contact with the gastric juice. The objection to the soluble pepsins is that they are hygroscopic; but they are, when good, well suited for making solutions, wines, etc.

Pepsin should always be administered in its original form. The wines and elixirs which flood the market are mostly worthless preparations, although it has been proved that an effective wine of pepsin can be made, and *small quantities of alcohol* are not incompatible.* It is well to combine it with hydrochloric acid, and the powder is often advantageously exhibited in *infantile diarrhœa* along with bismuth subnitrate. With these exceptions, it is usually preferable to give it by itself.†

Medical Properties and Uses. Pepsin is said to have been first suggested as a remedy by Dr. Corvisart, of Paris (*Journ. de Pharm.*, xxx. 169), and has been very largely used in cases of various character in which the digestive powers of the stomach have failed, for the purpose of supplying the place of the natural digestive ferment. Any influence for good which it possesses is dependent upon its solvent power, which is a measure of its value. The usual dose of pepsin is from ten to fifteen grains, and it is plain that the solvent power of less than such an amount is too trifling to be of value in sustaining the digestion of an adult. Further, a large portion of the pepsin which has been exhibited has been inert, either originally or from the method of its administration; and in the great majority of cases the good result that has been ascribed to the pepsin has been due, not to it, but to the regulation of the diet and habits of the patient and to the drugs which have been exhibited along with the animal ferment. We believe that its value has been overestimated, that it has been given to adults in ridiculously small doses, and that a drachm (3·9 Gm.) of the ordinary commercial article or of saccharated pepsin is a moderate dose. It has been found much more certain in its effects in the feeble digestion of infants than of adults, due probably to its being administered in proportionately much larger doses. To a babe six months old, suffering from *indigestion* and consequent *diarrhœa*, one grain of pepsin or ten grains of saccharated pepsin may be given after each feeding with a rational expectation of benefit. The dose of best quality pepsin may be set down as from ten to fifteen grains (0·648–0·972 Gm.).

* *Liquor Pepsini.* U. S. 1880. *Solution of Pepsin.* [*Liquid Pepsin.*] (*Pepsine liquide*, Fr.; *Pepsin-Lösung*, G.) "Saccharated Pepsin, *forty parts* [or four hundred grains]; Hydrochloric Acid, *twelve parts* [or one hundred and ten minims]; Glycerin, *four hundred parts* [or seven fluidounces]; Water, *five hundred and forty-eight parts* [or twelve fluidounces], To make *one thousand parts* [or about twenty fluidounces]. Dissolve the Saccharated Pepsin in the Water, previously mixed with the Hydrochloric Acid, add the Glycerin, let the mixture stand twenty-four hours, and filter. This preparation originated with Prof. Emil Scheffer, who suggested a process (see *A. J. P.*, 1870, p. 98), in which six pounds of the mucous membrane of hogs' stomachs were macerated with four pounds of glycerin and four pints of water containing six ounces of hydrochloric acid for thirty-six hours. The mass was then strained, and macerated with fresh water and again strained, and the operation repeated until ten pints were obtained. This process was simplified after the publication of his formula for Saccharated Pepsin, was official in 1880, and is based upon this later process. The solution contains 4 per cent. of Saccharated Pepsin, whilst Scheffer's original formula (*A. J. P.*, 1871, p. 5) was weaker, containing but 1·6 per cent. This liquid is transparent, either colorless, or having a yellowish color, and a sweetish, agreeable taste, which is slightly acidulous. 'It should not become mouldy, nor acquire a disagreeable, fetid odor, when kept for some time.' *U. S.* It should be freshly made, as it gradually loses its powers of digestion when long kept. This preparation, if in good condition, undoubtedly has all the remedial virtues of pepsin, and should be used to the exclusion of all the elixirs. The dose is one-half to two fluidounces (15 to 60 C.c.)." *U. S. D.*, 16th ed.

† Gastric juice was many years ago employed by Dr. P. S. Physick, the celebrated surgeon of Philadelphia, with considerable success, as a local application to cancers and sloughing ulcers, with the view of removing the dead bone and flesh, correcting the offensive odor, and yielding a healthful stimulus to the diseased surface. It has also been used with success, by Dr. Ellsworth, of Hartford, Connecticut, for dissolving a portion of tough animal food which had become impacted in the œsophagus of a lad affected with stricture of that passage. The gastric juice of a pig was used. (*Bost. Med. and Surg. Journ.*, April 17, 1856.) The inner coat of the gizzard of the South American ostrich is said, in the state of powder, to be used in Buenos Ayres as a remedy in dyspepsia (E. S. Wayne, *A. J. P.*, March, 1868, p. 123), and the dried crops and gizzards of chickens and turkeys have long been used in some portions of this country as a domestic remedy. For an account of *Rennet*, see PART II.

PEPSINUM SACCHARATUM. U. S. Saccharated Pepsin.

(PĔP-SĪ'NŬM SĂC-ȻHĄ-RĀ'TŬM.)

"Pepsin, *ten grammes* [or 154 grains]; Sugar of Milk, recently dried, and in No. 30 powder, *ninety grammes* [or 3 ounces av., 76 grains], To make *one hundred grammes* [or 3 ounces av., 230 grains]. Triturate the Pepsin with the Sugar of Milk to a fine, uniform powder. Keep the product in well-stoppered bottles." *U. S.*

As stated in the article "Pepsinum," this powder is made by diluting strong pepsin with powdered sugar of milk. It is about six times stronger than the saccharated pepsin of the U. S. P. 1880. (See preceding article.) "Saccharated Pepsin, when tested by the process given under Pepsin (see *Pepsinum*), with the modification that 0·67 Gm. of it are to be taken in preparing solution *B*, should digest 300 times its own weight of freshly coagulated and disintegrated egg albumen." *U. S.*

PETROLATUM LIQUIDUM. U. S. (Br.) Liquid Petrolatum.

(PĔT-RŌ-LĀ'TŬM LĬQ'UĮ-DŬM.)

"A mixture of hydrocarbons, chiefly of the marsh-gas series, obtained by distilling off the lighter and more volatile portions from petroleum, and purifying the residue when it has the desired consistence." *U. S.* "A clear oily liquid, obtained from petroleum, after the more volatile portions have been removed by distillation." *Br.*

Paraffinum Liquidum, *Br.,* Liquid Paraffin.

PETROLATUM MOLLE. U. S. (Br.) Soft Petrolatum. [Soft Petroleum Ointment.]

(PĔT-RŌ-LĀ'TŬM MŎL'LĒ.)

"A mixture of hydrocarbons, chiefly of the marsh-gas series, obtained by distilling off the lighter and more volatile portions from petroleum, and purifying the residue when it has the desired melting point. When Petrolatum is prescribed or ordered without further specification, Soft Petrolatum (*Petrolatum Molle*) is to be dispensed." *U. S.* "A semi-solid mixture containing soft members of the paraffin series of hydrocarbons; usually obtained by purifying the less volatile portions of petroleum." *Br.*

Paraffinum Molle, *Br.;* Petrolatum, *U. S.* 1880; Soft Paraffin; Pétroléine; Unguentum Paraffinum.

PETROLATUM SPISSUM. U. S. Hard Petrolatum.

(PĔT-RŌ-LĀ'TŬM SPĬS'SŬM.)

"A mixture of hydrocarbons, chiefly of the marsh-gas series, obtained by distilling off the lighter and more volatile portions from petroleum, and purifying the residue when it has the desired melting-point." *U. S.*

Petrolatum, *U. S.* 1880; Hard Petroleum Ointment.

Petrolatum in its various forms has of late years acquired considerable importance, under various trade names, as a bland neutral body well fitted to take the place of lard as a base for ointments and for other purposes. It is prepared from the residuum left in the stills after a distillation of petroleum *in vacuo*, or from the residue or sediment deposited in tanks containing crude petroleum, of which large quantities have collected in the storing-tanks in the oil-districts of Western Pennsylvania. The substances known commercially as *cosmoline* (*Unguentum Petrolei*) and *vaseline* are now made on a large scale from residuums, but more largely from what are termed "reduced oils," that is, crude oils from which the lighter fractions (those included under the heads of benzin, naphtha, illuminating and paraffin oils) have been removed by distillation. This process of reducing would leave an increasing amount of black pyrogenous products in the residuum, were it not that the reducing is carried out under diminished pressure, by what is termed the "vacuum process," in which, moreover, the heat is not applied directly to the still bottoms, but by means of coils of pipe, through which superheated steam is made to pass. These reduced oils can be brought to 337·7° C. (640° F.) fire-test without acquiring the slightest pyrogenous odor. They are then filtered through well-dried bone-black, in chambers kept at a temperature of from 43·3° to 54·4° C. (110° to 130° F.), or in some cases higher. The first portions of the filtrate are colorless, and then pass from a light straw or amber color to a color red by transmitted light and light green by reflected light. This latter is known as "cylinder stock," and is highly prized as a lubricating oil. The clearer portion of the filtrate is then brought to the proper melting-point, if neces-

sary, by the addition of pure block paraffin, which dissolves perfectly in the warm liquid oil. The storing-tank residue is purified in a similar manner. The "B. S. Oil," or "rod wax," as it is technically termed, is placed in a still, heat applied, and after the lighter products have distilled over, and indications of congelation are noticed when a portion of the distillate is allowed to cool, the heat is withdrawn, and the contents of the still, after having cooled, are transferred gradually to a percolator which contains recently heated animal charcoal. In place of bone-black, clay has in recent years been quite largely used for clarifying purposes, the same being revivified by heat. A somewhat different process is used in Germany: the crude product is derived from crude *ozokerite*, obtained from Alsace and Galicia, or American residuum is sometimes used. 1. The oil is heated by steam to about 30° C. (86° F), mixed, at this temperature, with 10 per cent. of its weight of sulphuric acid of 60° B., stirred for half an hour, and then allowed to stand at rest, so that the carbonized portions may separate. 2. When clear, the oil is washed with an aqueous solution of potassium bichromate, whereby any remaining excess of sulphuric acid is at the same time removed. 3. The residue from the acid treatment is mixed with lime, neutralized, and disposed of to manure-factories. 4. The clear oil from the second step of the process, after being washed, is heated by steam to 80° C. (176° F.), mixed with 10 per cent. of its weight of granular animal charcoal, and then allowed to stand at rest, to permit the animal charcoal to settle. 5. After the latter is separated, the liquid portion is filtered through filters heated by steam. 6. The residuary magma of animal charcoal is subjected to hydraulic pressure, the expressed oil filtered, and the solid residue again used in the next operation, a sufficient quantity of fresh animal charcoal being added to make up for any loss or waste. (*Pharm. Centralhalle*, 1881, No. 42; *N. R.*, Feb. 1882.)

The commercial varieties of petrolatum may be classed under two heads: (1) those which, like the American vaseline, are obtained as a ready-formed mixture of hydrocarbons of gelatinous consistence; and (2) those made by directly mixing solid paraffin of low melting-point with heavy lubricating oil, such as are known in Germany as "artificial vaseline." The latter varieties are less homogeneous, and are liable to deposit granules of paraffin on keeping, and hence are not so suited for the preparation of ointments as true American petrolatum.

In warm ether, American petrolatum dissolves freely to a clear solution exhibiting a strong blue fluorescence, and the liquid remains clear, or at most becomes only slightly turbid, on cooling. German petrolatum, on the contrary, is said to form a thick solution with warm ether, and to give a considerable deposit on cooling. Russian petrolatum is stated to dissolve completely in warm ether and give a clear solution which becomes turbid on cooling. (Allen, *Commerc. Org. Anal.*, 2d ed., 1887, ii. p. 408.)

Chemical Constitution. Petrolatum, as made from American petroleum, consists mainly of the higher members of the paraffin series, but undoubtedly contains also the higher olefines. These may possibly alter in time, and give rise to rancidity, although this is not certainly established. The paraffins, which make up the bulk of it, are not capable of direct oxidation, and are therefore not affected by atmospheric influences. Petrolatum contains hydrocarbons of the paraffin series, like $C_{16}H_{34}$, $C_{17}H_{36}$, $C_{18}H_{38}$, etc., up probably to $C_{32}H_{66}$, together with hydrocarbons of the olefine series, $C_{16}H_{32}$, $C_{17}H_{34}$, etc. These latter are less concrete than the corresponding paraffin hydrocarbons, and give Petrolatum its oleaginous characters.

Properties. The U. S. Pharmacopœia describes Petrolatum as follows:

Liquid Petrolatum. "A colorless, or more or less yellowish, oily, transparent liquid, without odor or taste, or giving off, when heated, a faint odor of petroleum. Specific gravity, about 0·875 to 0·945 at 15° C. (59° F.). Insoluble in water; scarcely soluble in cold or hot alcohol, or in cold absolute alcohol; but soluble in boiling absolute alcohol, and readily soluble in ether, chloroform, carbon disulphide, oil of turpentine, benzin, benzol, and fixed or volatile oils. When heated on platinum, Liquid Petrolatum is completely volatilized, without emitting any acrid vapors. The alcoholic solution of Liquid Petrolatum is neutral to litmus paper. If 5 Gm. of Liquid Petrolatum be digested, for half an hour, with 5 Gm. of sodium hydrate and 25 C.c. of water, the aqueous layer separated, and supersaturated with sulphuric acid, no oily substance should separate (absence of *fixed oils or fats of animal or vegetable origin*, or of *resin*). If 2 volumes of concentrated sulphuric acid be added to 1 volume of Liquid Petrolatum, in a test-tube placed in hot water, and the contents occasionally agitated during fifteen minutes, the acid should not acquire a deeper tint than brown, nor lose its transparency (limit of *readily carbonizable organic impurities*)."

Soft Petrolatum. "A fat-like mass, of about the consistence of an ointment, varying from white to yellowish or yellow, more or less fluorescent when yellow, especially after being melted,

transparent in thin layers, completely amorphous, and without odor or taste, or giving off, when heated, a faint odor of petroleum. If a portion of Soft Petrolatum be liquefied, and brought to a temperature of 60° C. (140° F.), it will have a specific gravity of about 0·820 to 0·840. The melting point of Soft Petrolatum ranges between about 40° and 45° C. (104° and 113° F.). In other respects Soft Petrolatum has the characteristics of, and should respond to the tests given under, Liquid Petrolatum (see *Petrolatum Liquidum*)."

Hard Petrolatum. "A fat-like mass, of about the consistence of a cerate, varying from white to yellowish or yellow, more or less fluorescent when yellow, especially after being melted, transparent in thin layers, completely amorphous, and without odor or taste, or giving off, when heated, a faint odor of petroleum. If a portion of Hard Petrolatum be liquefied, and brought to a temperature of 60° C. (140° F.), it will have a specific gravity of about 0·820 to 0·850. The melting point of Hard Petrolatum ranges between about 45° and 51° C. (113° and 125° F.). In other respects Hard Petrolatum has the characteristics of, and should respond to the tests given under, Liquid Petrolatum (see *Petrolatum Liquidum*)."

The British Pharmacopœia describes *Paraffinum Liquidum* as "Colorless, odorless, tasteless, not fluorescent. Boiling point not below 680° F. (360° C.). Specific gravity from 0·885 to 0·890. 3 cubic centimetres, heated with an equal volume of *sulphuric acid* in a test-tube placed in boiling water for 10 minutes, with frequent agitation, should not color the separated layer of acid of a deeper tint than pale brown. *Alcohol* (90 per cent.) boiled with Liquid Paraffin should not redden *blue litmus paper* (absence of acid). A mixture of 4 cubic centimetres with 2 of *absolute alcohol*, and 2 drops of a clear saturated solution of Lead Oxide in *solution of sodium hydroxide*, should remain colorless when kept at 158° F. (70° C.) for 10 minutes (absence of sulphur compounds)." *Paraffinum Molle.*—"White or yellow, translucent, soft, unctuous to the touch, free from acidity, alkalinity, or any unpleasant odor or flavor, even when warmed to 120° F. (48·9° C.). Specific gravity at the melting point 0·840 to 0·870. Melts at 96° to 102° F. (35·5° to 38·9° C.) or even somewhat higher, volatilizes without giving off acrid vapors, and burns with a bright flame, leaving no residue. Insoluble in *water*, slightly soluble in *absolute alcohol*, freely soluble in *ether*, *chloroform*, and *benzol*. After treating with boiling *solution of sodium hydroxide* the aqueous liquid yields no precipitate or oily matter on adding excess of acid (absence of fixed oils, fats, and resin)." *Br.* As it is found in the market, Petrolatum varies in color, odor, and melting point. The statement frequently made by the manufacturers that it is unalterable in the air is incorrect, as we have frequently noticed that exposure to light and air causes it to assume a disagreeable odor resembling that of crude petroleum. It has been observed to have at times irritating properties. These may be due to imperfect removal of the sulphuric acid or similar agents used, but are more probably caused by rancidity of the higher olefines.

Medical Properties. Petrolatum is used exclusively as a bland neutral protective dressing, and as a substitute for fatty materials in ointments. Dr. M. M. Griffith (*N. R.*, May, 1880) asserts that the crude semi-solid petroleum (*rod wax*), as it accumulates on the casings, etc., about oil-wells, is an invaluable remedy in *chronic bronchitis* and *incipient phthisis*. It is readily formed into three-grain pills, and may be given until it produces eructations. He has used the following formula with advantage: ℞ Petroleum mass, ℥i; Pulv. Cubebæ, Pulv. Doveri, āā ʒvi, to make pill mass (pills 5 gr.). *Huile de Gabian* is a similar product, which has long been famous in France as a remedy in lung diseases. Dr. N. Randolph has shown that when taken internally, in doses of from one to four drachms, cosmoline acts simply as a feeble laxative and soothes irritation, so as to be advantageous in inflammations of the gastro-intestinal mucous membrane. Liquid petrolatum is much used as a soothing local application in inflammation of the mucous membranes in the nose, throat, larynx, and even bronchial tubes. It is usually applied by means of an atomizer, and can be made the vehicle for carrying medicinal substances.

PHENACETINUM. Br. Phenacetin.

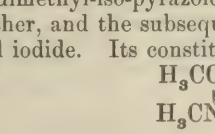
$C_{10}H_{13}NO_2$. (PHĒ-NĂC-Ē-TĪ'NUM.)

"Para-acet-phenetidin, $C_2H_5O.C_6H_4.NHCOCH_3$, or Phenacetin, is produced by the interaction of glacial acetic acid and para-phenetidin, a body obtained from para-nitrophenol." *Br.*

The chemical relationship of this body to phenol is seen by an examination of its formula and the formulas of the intermediate compounds obtained as stages in its preparation.

Phenol, $C_6H_5.OH$, is converted into *nitrophenol*, $C_6H_4(NO_2)OH$. Only the paranitrophenol is available, and this is separated by distilling off the ortho-nitrophenol by steam distillation.

The residual *paranitrophenol*, in the form of the sodium compound, is treated with ethyl bromide, when ethyl paranitrophenol or *paranitrophenetol*, $C_6H_4(NO_2)OC_2H_5$, is produced. This is now reduced by the action of muriatic acid and iron turnings to *paraphenetidin*, $C_6H_4(NH_2)OC_2H_5$. Glacial acetic acid then serves to introduce the acetyl group, and *paracetamidophenetol*, or phenacetin, $C_6H_4(NHC_2H_3O)OC_2H_5$, is obtained.



Properties. Phenacetin occurs in crystalline scales which are colorless, tasteless, and without odor, melting at 135° C. (275° F.), slightly soluble in cold water, more freely soluble in boiling water (one part in seventy), and soluble in sixteen parts of alcohol. The British Pharmacopœia gives the following tests. "0·1 gramme boiled with 2 cubic centimetres of *hydrochloric acid* for half a minute yields a liquid which, diluted with ten times its volume of *water*, cooled, and filtered, assumes a deep-red coloration on the addition of *solution of chromic acid*. Heated with free access of air it burns, leaving no residue. *Sulphuric acid* dissolves it without color. A cold saturated aqueous solution should not become turbid on the addition of *solution of bromine* (absence of acetanilide). A mixture of 0·3 gramme of Phenacetin with 1 cubic centimetre of *alcohol* (90 per cent.) should not acquire a red tint when diluted with three times its volume of *water*, and boiled with one drop of *volumetric solution of iodine* (absence of paraphenetidin)." The test with chromic acid will serve to distinguish it from acetanilid and exalgin; that with bromine water will indicate the absence of phenol and acetanilid, both of which will show a white turbidity, owing to the formation of difficultly soluble bromine derivatives. The presence of unchanged paraphenetidin may be detected by melting 2·5 Gm. of chloral hydrate in a test-tube and adding 0·5 Gm. of the phenacetin to be tested. If pure, it will remain colorless; if paraphenetidin be present, it will become violet or reddish blue in tint. For other tests, see *New England Drug.*, 1894, 135.

Medical Properties and Uses. Phenacetin was first introduced as an antipyretic by Hinsberg and Kast, who found that in order to produce toxic effects in the lower animals enormous doses are required. These cause vomiting, staggering, hurried respiration, somnolence, cyanosis, and methæmoglobinization of the blood. In man no fatal cases of poisoning have been reported, but Hollopeter saw twenty-two and a half grains produce in a woman collapse, with cyanosis. Phenacetin would seem to be one of the safest, as it certainly is one of the most efficient, drugs of its class. It is asserted that its antipyretic action is more gradual, more prolonged, and less apt to be attended with disagreeable symptoms than that of antipyrin and other allied drugs. The experiments of Ott and of Cerna and Carter appear to prove that the fall of temperature produced by phenacetin is due to a lessened production of animal heat caused by a direct influence of the drug upon the thermo-genetic centres, and is not necessarily accompanied by any distinct alteration of the circulation. Indeed, the experiments of Cerna and Carter indicate that, by stimulating the heart and the vaso-motor system, very large therapeutic doses increase arterial pressure, although after toxic doses there is a fall of blood-pressure, due chiefly to cardiac paralysis. As an *antipyretic* and as an *analgesic* phenacetin appears to cover in its usefulness the same range as does antipyrin. In *nervous headache* the combination of it with caffeine (twelve grains to three) is often singularly advantageous. By many phenacetin is believed to be less depressing than is antipyrin. Urticaria has been noted after phenacetin, but it seems not to produce any characteristic eruption. Dose, from ten to twenty grains (0·65–1·3 Gm.). According to Herr Reuter, *paraphenetidin*, which is liable to occur in commercial phenacetin, is a dangerous poison, especially acting upon the kidneys.

PHENAZONUM. Br. Phenazone.

$C_6H_5(CH_3)_2C_3HN_2O$. (PHĒ-NA-ZŌ'NŬM.)

"Phenazone, or phenyl-dimethyl-iso-pyrazolone, is obtainable from phenyl-hydrazine by interaction with aceto-acetic ether, and the subsequent interaction of the resulting phenyl-methyl-iso-pyrazolone with methyl iodide. Its constitution is indicated by the following formula:

NC_6H_5." *Br.*

Antipyrin, Phenyl-dimethyl-iso-pyrazolone; Antipyrine, *Fr.*; Antipyrin, *G.*

This substance was introduced into the British Pharm. 1885 "Additions," under the name of "Phenazonum." It has not been recognized by the U. S. Pharm. 1890, because its method of production is controlled by the monopoly manufacturing it, and hence tests which

would be prescribed by the Pharmacopœia could be made inoperative at any time that the manufacturers chose to change the character of the product. The British Pharmacopœia, however, introduces the substance under a specially coined title, which has not received recognition to any extent, the drug being almost universally prescribed under the name of antipyrin.

This compound is perhaps the most important of the newer synthetical remedies introduced into medicine: it is now generally conceded to be a derivative of pyrrol, C_4H_5N, a base found in coal-tar and in bone oil. From this base, $\begin{matrix}HC{=}CH\\ \vert\\ HC{=}CH\end{matrix}\!>\!NH$, pyrazole, $\begin{matrix}HC{=}N\\ \vert\\ HC{=}CH\end{matrix}\!>\!NH$, is derived (see PART II.); from this pyrazolon, $\begin{matrix}HC{=}N\\ \vert\\ H_2C{-}CO\end{matrix}\!>\!NH$, which by molecular rearrangement yields isopyrazolon, $\begin{matrix}CH{-}NH\\ \Vert\\ CH{-}CO\end{matrix}\!>\!NH$. Phenyl-dimethyl-iso-pyrazolon, $\begin{matrix}(CH_3)C{-}N(CH_3)\\ \Vert\\ HC{-}CO\end{matrix}\!>\!N(C_6H_5)$, is a substitution product from this. Practically it is made by Knorr's patented process of acting upon phenyl-hydrazine, $C_6H_5{-}HN{-}NH_2$, with ethyl aceto-acetate, $(CH_3.CO)CH_2.CO.C_2H_5$, when phenyl-methyl-pyrazolon, $\begin{matrix}(CH_3)C{=}N\\ \vert\\ H_2C{-}CO\end{matrix}\!>\!N(C_6H_5)$, is formed. This is then methylated by treatment with methyl iodide, when the hydriodide of the finished base results. The product of another reaction—viz., that of a halogen butyrate upon phenyl-hydrazine and subsequent oxidation and methylation of the compound so obtained, which is also a phenyl-dimethyl-pyrazolon—is, however, only an isomer of the true antipyrin and not identical with it. It is described in the British Pharmacopœia as "In colorless and inodorous scaly crystals with a bitter taste. Melting point about 235·4° F. (113° C.). Soluble in its own weight of *water*, in 1½ parts of *alcohol* (90 per cent.) or of *chloroform*, and in 40 parts of *ether*. 0·1 gramme of *sodium nitrite* and 12 cubic centimetres of a 1 per cent. aqueous solution of Phenazone yield a nearly colorless liquid which turns deep green on the addition of 1 cubic centimetre of *diluted sulphuric acid*. An aqueous solution of the same strength mixed with an equal volume of *nitric acid* assumes a yellow color, passing to crimson on warming. *Test-solution of ferric chloride* produces in a very dilute aqueous solution a deep red color, which is nearly discharged by excess of *diluted sulphuric acid*. A 5 per cent. aqueous solution of Phenazone gives with *test-solution of mercuric chloride* a white precipitate which disappears on boiling, but reappears as the liquid cools. The aqueous solution should not affect *solution of litmus*, and should not be affected by *hydrogen sulphide*. 2 cubic centimetres of a 1 per cent. aqueous solution should be colored green by 2 drops of *fuming nitric acid*, and the color should be changed to red by boiling with an additional 3 or 4 drops of the acid."

Medical Properties and Uses. Antipyrin, when given in such doses as simply to produce physiological effects, causes languor, malaise, a peculiar livid complexion, and in many cases an eruption upon the skin very closely resembling measles. In some instances an erythema or a violent urticaria or even wide-spread œdematous dermatitis is produced. When these skin symptoms are severe, the mucous membranes may share in the irritation, and a general rise of temperature, dyspnœa, hysterical unrest, and even more severe constitutional symptoms come on. The ordinary symptoms of poisoning by antipyrin are cephalic distress, giddiness, tremblings, excessive sweating, increased frequency of the pulse, often accompanied by præcordial anguish, fall of temperature, arrested respiration, exaggeration of the reflexes, followed, if the dose have been large enough, by somnolence deepening into coma, and passing into profound stertorous unconsciousness, with dilatation of the pupil and epileptiform convulsions. In some cases of poisoning the chief symptoms have been those of profound progressive collapse. Various irregular symptoms have been noted, such as amaurosis, pseudo-membranous stomatitis, swelling of the lips and tongue, laryngeal interference with the respiration. When antipyrin is given in fever it acts as a very powerful and certain antipyretic, the fall of temperature usually appearing in half an hour after the dose, and being very marked and continuing for some hours. It is usually, but not always, accompanied by a profuse sweat, which is not, however, the cause of the fall of temperature, as the latter may occur without the sweat, and is not prevented by hypodermic injections of atropine which check the perspiration. With the fall of temperature there is usually a decrease in the rate but not in the force of the pulse. Physiological doses of antipyrin have very little influence upon the circulation, and a reduction of temperature in fevered animals of four or five degrees with complete steadiness of the arterial pressure may be often observed. That the fall of temperature

is not due to an action upon the circulation is further shown by the calorimetrical experiments of Drs. H. C. Wood, Reichert, and Hare, which demonstrate that there is an absolute decrease in the production of animal heat caused by the action of the drug upon the nervous system.

The work of physiologists has proved that antipyrin has a peculiar influence upon the cerebral cortex; that when in toxic dose it probably acts as a primary stimulant and a secondary depressant to the spinal cord; that it paralyzes both the motor and the sensory nerve-trunks, and has some distinct but feeble influence upon the muscles themselves; that in very large doses it increases the arterial pressure, although toxic doses decrease the pressure, probably in part by an action upon the vessels and in part by an action upon the heart; that upon the respiration antipyrin has no distinct influence, unless in toxic dose, when it seems to act as a primary stimulant and secondary depressant to the respiratory centres.

The absorption and elimination of antipyrin are rapid: it has been detected in the urine in less than half an hour after its ingestion. The chief channel of escape is the kidneys, but it has been detected in the milk of nursing women. It appears in health and in fever to diminish the elimination of urinary solids, and the whole output from the body of the nitrogenous products of tissue-waste. A peculiar livid discoloration of the surface of the body is one of the most characteristic symptoms of antipyrin poisoning, and is probably due to the formation in the blood of methæmoglobin or of some similar compound.

Antipyrin has been used in practical medicine to meet various indications. First, for the relief of pain. As an analgesic it is of no value when the pain is dependent upon a local inflammation, but it is often remarkably efficient in *migraine*, in the fulgurant pains or the pain-crises of *locomotor ataxia*, and in other paroxysms of suffering dependent upon disease of the nerve-centres or having the character of nerve-storms; it is also useful in the pains of *rheumatism* and of *neuritis*. It has been strongly recommended by some obstetricians as an analgesic in the first stages of labor, but in most cases it fails to achieve distinct results. Second, for the quieting of nervous irritation. Thus, it has been employed with alleged extraordinary results by Dr. Nitot in nervous *urticaria*, has been used by Dr. Thör in *nocturnal emissions*, and is often employed in hysterical unrest. Third, for the purpose of combating excitability of the motor nerve-centres, as in *laryngismus stridulus*, *chorea*, *whooping-cough*, *tetanus*, *epilepsy*. In the latter disease it usually fails, but sometimes acts with extraordinary power. The combination of it with ammonium bromide is much more efficacious in epilepsy than are the bromides by themselves. Fourth, to affect secretion, as in infantile *diarrhœa*, in *diabetes*, true and insipid, and as an antigalactagogue when it is desired to arrest secretion of milk. Clément (*Lyon Méd.*, 1891) affirms that it is remarkably effectual in bringing about the absorption of pleuritic effusions. Fifth, as an antipyretic. For this purpose it has been employed in all diseases with high temperature, and, as it has little influence upon the circulation, may be used in asthenic fevers. Usually the fall of temperature which it produces is accompanied by marked increase in the comfort of the patient, but occasionally severe collapse occurs, and the lowering of the temperature produced by antipyrin and allied drugs is not accompanied by as much benefit to the patient as results from the reduction of fever-heat by the cold bath. Sixth, as a local anæsthetic. M. St.-Hilaire affirms that it is even more efficacious than cocaine when applied to the mucous membranes in a solution of from thirty to fifty per cent. Seventh, as a local hæmostatic. Henocque and Huchard, and also Moncorvo, assert that in from five- to fifteen-per-cent. solution it will arrest almost any nasal hemorrhage, and in stronger solution is efficacious in hemorrhages of all kinds.

Antipyrin has in a number of cases produced serious poisoning, and sometimes acts out of all proportion to the amount of the drug which has been exhibited. The hypodermic injections at times produce local irritation, but usually they are well borne. The full antipyretic dose for the adult should not exceed twenty grains (1·29 Gm.), repeated in half the quantity every half hour until forty grains have been taken or a fall of temperature or sweating occurs. The analgesic dose is from ten to fifteen grains (0·65–1·0 Gm.); in epilepsy ten grains (0·65 Gm.) a day may be continuously exhibited.

PHOSPHORUS. U. S., Br. Phosphorus.

P; 30·96. (PHŎS'PHO-RŬS.) P; 31.

"Phosphorus should be carefully kept under water, in strong, well-closed vessels, in a secure and moderately cool place, protected from light." *U. S.* "A solid non-metallic element obtained from calcium phosphate." *Br.*

Phosphore, *Fr.;* Phosphor, *G.;* Fosforo, *It., Sp.*

This non-metallic element was discovered in 1669 by Brandt, an alchemist of Hamburg, who obtained it from evaporated urine by a process which remained a secret until 1737. As thus procured, it was exceedingly scarce and costly. In 1769 the Swedish chemist Gahn discovered it in bones, and shortly afterwards published a process by which it might be extracted.

Preparation. Powdered calcined bones (calcium bone-phosphate) are digested for twenty-four hours with two-thirds of their weight of sulphuric acid previously diluted with twelve times its weight of water. The sulphuric acid separates the greater part of the lime from the phosphoric acid, and precipitates as calcium sulphate, while an acid calcium phosphate ($CaH_4(PO_4)_2$) remains in solution. The liquid is then strained through a linen cloth to separate the calcium sulphate, and afterwards submitted to evaporation, which causes a fresh precipitation of sulphate, to be separated by a new straining. The strained solution is evaporated to a syrupy consistence, and then thoroughly mixed with half its weight of powdered charcoal, so as to form a mass, which is dried by being heated to dull redness. At this temperature the acid phosphate is changed into metaphosphate ($Ca(PO_3)_2$) by the loss of two molecules of water. The mass when cool is quickly transferred to a coated earthenware retort, furnished with an adapter of copper, bent downward at right angles, so as to enter a bottle with a large neck containing water, which should rise about two lines above the orifice of the adapter. The bottle is closed round the adapter with a cork, which is traversed by a small glass tube, to give exit to the gaseous products. The retort is heated in a furnace, furnished with a dome, in the most gradual manner, so as to occupy about four hours in bringing it to a red heat. Afterwards the heat is pushed vigorously, so long as any phosphorus drops into the water; and this takes place generally for from twenty-four to thirty hours. During this part of the process the metaphosphate is decomposed, its oxygen combining with the charcoal, and the liberated phosphorus distilling over. The calcined bones of the sheep are preferred, as they contain the largest proportion of calcium phosphate and are most readily acted on by the acid.

The electrolytic phosphorus process, first brought out by Readman and Parker some five years ago, has now practically displaced the older methods for the production of phosphorus. Albright & Wilson, who formerly manufactured phosphorus by the old method at Oldbury, England, have built works at Niagara Falls, and entirely control the production in the United States and England.

A mixture of calcium phosphate, carbon, and sand or kaolin is submitted to the temperature of the electric arc while packed in a covered plumbago crucible. The phosphorus is distilled off in a current of illuminating gas. It is very pure, and it is claimed that 86 per cent. is recovered. The native Redonda phosphate, an aluminum phosphate, is also taken for this process instead of the calcium phosphate, and phosphorus obtained from it without any previous purification. The great bulk of the phosphorus is consumed in the manufacture of matches, a smaller amount in the production of phosphor bronze, and another portion in making the chemical compounds of the element.

Properties. Phosphorus is a semi-transparent solid, without taste, but possessing an alliaceous smell. When perfectly pure it is colorless; but as usually prepared it is yellowish or reddish yellow. It is flexible, and when cut exhibits a waxy lustre. It is said by M. Boettger to be easily pulverizable by agitation with a solution of urea. (*Journ. de Pharm.*, Juin, 1863, p. 488.) "It has a distinctive and disagreeable odor and taste (*but should not be tasted, except in a state of great dilution*). When exposed to the air, it emits white fumes, which are luminous in the dark, and have an odor somewhat resembling that of garlic. On longer exposure to air, it takes fire spontaneously. Specific gravity, 1·830 at 10° C. (50° F.). Melting point, 44° C. (111·2° F.). Phosphorus is insoluble or nearly so in water, to which, however, it imparts its characteristic, disagreeable odor and taste. Soluble in 350 parts of absolute alcohol at 15° C. (59° F.), in 240 parts of boiling absolute alcohol, in 80 parts of absolute ether, in about 50 parts of any fatty oil, and very soluble in chloroform, or in carbon disulphide,* the latter yielding a solution which must be handled with the greatest care to prevent danger from fire. To test for *arsenic* and *sulphur* proceed as follows: Add 3 Gm. of Phosphorus to 15 C.c. of nitric acid diluted with 15 C.c. of distilled water in a flask having the capacity of 50 C.c., and digest the mixture at a gentle heat on a water-bath, until the Phosphorus is dissolved. Transfer the solution to a capsule, and evaporate it until no more nitrous vapors are given off, and then dilute the solution to 30 C.c. with distilled water. Heat 20 C.c. of the diluted solution to about 70° C. (158° F.) for half an hour, passing hydrogen sulphide through it during the half-hour's

* According to Flückiger, carbon disulphide is capable of dissolving twenty times its weight of phosphorus without losing its fluidity.

heating, and then until the liquid has become cold. If the liquid be now allowed to stand at rest during twenty-four hours, not more than a very small quantity of lemon-yellow precipitate should be visible (limit of *arsenic*). On adding barium chloride test-solution to the remainder of the liquid, not more than a slight opalescence should be produced (limit of *sulphur*." *U. S.* "Specific gravity 1·77. It is soft and flexible at common temperatures, melts at 110° F. (43·3° C.), ignites in the air at a temperature a little above its melting point, burns with a luminous flame, and produces dense white fumes. It is insoluble in *water*, but soluble in 350 parts of *absolute alcohol*, in 80 parts of *olive oil*, in 80 parts of *ether*, in 25 parts of *chloroform*, in half its weight of *carbon bisulphide*, and in boiling *oil of turpentine*. 1 or 2 grammes should be attacked slowly and be dissolved without residue on being boiled with 5 or 10 cubic centimetres of *nitric acid* diluted with an equal volume of *water*, and the resulting solution should yield no characteristic reaction with the tests for arsenium, and only the slightest reactions with the tests for sulphates." *Br.* Its pulverization may be readily effected by melting it in hot water, and agitating until it is thoroughly cooled; and the powder is obtained finer in saline solutions than in pure water. (Blondlot, *Journ. de Pharm. et de Chim.*, 4e sér., i. 72, 1865.) It takes fire at 37·7° C. (100° F.), melts at 42·2° C. (108° F.), and boils at 287·7° C. (550° F.), air being excluded. During its combustion it combines with the oxygen of the air, and forms phosphoric oxide. On account of its great inflammability, it must be kept under water. When exposed to the air it undergoes a slow combustion, emitting white vapors, which are luminous in the dark. It sometimes contains arsenic, and therefore, when used in forming medicinal preparations, should be tested for that metal. Dr. C. J. Rademaker obtained out of 100 parts of phosphorus about one part of arsenic. (*A. J. P.*, Nov. 1870.) It occasionally contains antimony or sulphur, the latter rendering it brittle.

When phosphorus is kept in ordinary water it becomes covered with a whitish layer, of the nature of which there are different opinions, it being looked upon by some as a phosphorus hydrate, by others as an allotropic condition of that element, and by others again as a partial crystallization; but all these opinions have apparently been disproved by M. Ernest Baudrimont, who seems to have demonstrated that *white phosphorus* is entirely identical with that principle in its ordinary state, and results from a kind of erosion of the surface, owing to partial oxidation by the free oxygen held in solution by the water. The change never takes place in water entirely deprived of air; and the water when it has taken place holds phosphorous acid in solution. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 17, 1866.)

Prof. Schroetter, of Vienna, discovered an allotropic form of phosphorus, which he called *red* or *amorphous phosphorus*.* It is formed when ordinary phosphorus is kept long at a temperature between 215° C. (419° F.) and 250° C. (482° F.), in atmospheres which have no action on it, or in closed glass tubes. Red phosphorus is much more indifferent than the ordinary substance, and is denser, its sp. gr. being 2·11. It is much less easily acted on by the air than ordinary phosphorus, and is insoluble in carbon disulphide, alcohol, and ether, in all of which ordinary phosphorus is soluble. Solidified from the fused state, it is brittle, and breaks with a conchoidal fracture. Its hardness is considerable. Obtained by distillation in a non-acting gas, it is mixed with ordinary phosphorus, from which it may be freed by carbon disulphide, which dissolves the ordinary variety and leaves the allotropic as a deep red amorphous powder. It may also be purified by shaking it with a solution of calcium chloride of a density intermediate between that of red and that of ordinary phosphorus, and with a little carbon disulphide. The red variety will sink to the bottom, and the ordinary float on top of the solution, dissolved in the disulphide. (*E. Nicklès.*) Red phosphorus when pure is not poisonous. This has been proved beyond a doubt by the experiments of MM. Reynal and Lassaigne and of MM. L. Orfila and Rigaut. It is applicable to the manufacture of lucifer matches, and forms a much safer material than ordinary phosphorus. It does not take fire by friction at common temperatures, and therefore may be transported with the greatest safety. It has been said to be unchangeable in the air; but this is not exactly true, as proved by an observation of Mr. T. B. Groves, who, having set aside some red phosphorus in a bottle that was not air-tight, observed for a year or more no visible change, but found at length that it had be-

* E. Q. Thornton proposes the use of the *red amorphous phosphorus* as a safe substitute for phosphorus in medicine. In his own experiments upon animals he found that in large quantities it is non-toxic, but asserts that after its administration in increasing doses until three-tenths of a grain were taken every two hours (nine doses a day), it produced mental excitement, headache, vertigo, priapism, and nocturnal emissions, followed about the twentieth day by nervous exhaustion, with return to health in about two weeks after the discontinuance of the drug. It is obvious that the red phosphorus is physiologically very different from the ordinary form of the element; whether it may prove to be a useful stimulant in cases of sexual and other forms of exhaustion is not evident.

come decidedly altered, and ascertained that oxidation had taken place, with the result of forming a large quantity of phosphoric and phosphorous acids, in the proportion of 5 mols. of the former to 2 of the latter. (*P. J. Tr.*, June, 1865, p. 621.) Besides the white and red forms of phosphorus, there is another, called the *black*, first noticed by Thénard, and investigated by M. Blondlot, who found that it is pure phosphorus, and that its production is owing to some modification in the mode of cooling, when it has been in the liquid state. (*Journ. de Pharm. et de Chim.*, 4e sér., i. 407, 1865.) Prof. Flückiger doubts the existence of black phosphorus, however, and, after an investigation, states that the black color is due to arsenical contamination. (*Chem. Zeit.*, 1892, 181.)

Still another modification of phosphorus has been made known by M. Hittorf, who obtained it by heating red phosphorus and lead together in a close vessel. The lead on melting dissolved the phosphorus, and on cooling deposited it in the state of crystals resembling the crystals of arsenic. In this form, phosphorus is a conductor of electricity, and its sp. gr. at 16·6° C. (62° F.) is 2·34. M. Hittorf distinguishes it by the name of *metallic phosphorus*, and ranks it in the same category with red phosphorus, the latter differing simply in being amorphous. (*Chem. News*, March 23, 1866, p. 133.) M. Blondlot has succeeded in crystallizing common phosphorus by means of sublimation, operating in an atmosphere of nitrogen. (*Journ. de Pharm. et de Chim.*, 4e sér., iv. 321.)*

Phosphorus forms with oxygen two oxides,—*phosphoric*, P_2O_5, and *phosphorous*, P_2O_3. Corresponding to the first of these are three acids, known as *orthophosphoric* (tribasic phosphoric), H_3PO_4; *pyrophosphoric*, $H_4P_2O_7$, and *metaphosphoric*, HPO_3. The first of these is formed by dissolving P_2O_5 in boiling water, or by the action of nitric acid upon phosphorus itself; the second by the heating of the tribasic phosphoric acid to 213° C. (415·4° F.); and the third by the ignition of the tribasic variety, or by dissolving P_2O_5 in cold water. To the second oxide corresponds *phosphorous acid*, H_3PO_3, although it cannot be formed directly from the oxide. This is a dibasic acid, containing one hydrogen atom not replaceable by metal. To the hypothetical *hypophosphorous oxide*, P_2O, corresponds *hypophosphorous acid*, H_3PO_2. It is monobasic, containing two hydrogen atoms not replaceable by metal.

Medical Properties. Phosphorus, when given in small doses, is believed by some to act as a general stimulant. With more probability it is believed by most neurologists to act as a nutritive stimulant to the nervous system. Its usefulness in *sexual exhaustion*, in failure of the mental powers from similar causes, and indeed in all forms of exhaustion of the nerve-centres, when no organic lesion has occurred, seems unquestionable; and it may even be used, with hope of advantage, in *cerebral softening*. It is sometimes of service in *neuralgia*, and has been employed with asserted advantage in *mania*, in *melancholia*, and in *chronic eczema*, *psoriasis*, and other *affections of the skin*. When taken in large doses it is a deadly poison. The symptoms usually do not manifest themselves until some hours after the ingestion of the phosphorus. General malaise then becomes very pronounced, and is soon accompanied by nausea, abdominal pain, and vomiting of food, mucus, and bile. On the second and third day the vomiting is apt to cease, but the abdominal tenderness remains, and there is some fever. Jaundice also sets in, both the conjunctiva and the urine betraying its onset. The yellow color rapidly involves the whole surface. Early in the poisoning there is often great anxiety, restlessness, headache, and giddiness, but now delirium appears, wild, erotic, or low and muttering. Severe vomiting of a coffee-ground liquid, free from bile and similar to the black vomit of yellow fever, is now present; the urine is scanty and albuminous, often with tyrosine and leucine in it, or it may finally be suppressed. The temperature falls markedly, and the patient sinks into a coma which ends in death. After death a peculiar fatty degeneration is found affecting almost all the soft tissues. The parts which suffer first are the liver, the gastro-intestinal mucous membrane, and the kidneys. Very often the heart-muscle is also disorganized. The liver is always yellow, its cells engorged with fat-globules. At first it undergoes

* *Liquid Phosphorus.* A claim has been advanced by Prof. E. J. Houston to the discovery of another allotropic form of phosphorus characterized by being in the liquid state. Pure phosphorus was boiled repeatedly in strong solution of potassium hydrate, water being occasionally added to supply that lost by evaporation, and care taken to stir the liquid cautiously during the process. After five or ten minutes, the melted phosphorus was washed by a stream of pure water replacing the alkaline solution, and removing all the hypophosphites as well as liquid and gaseous hydrides of phosphorus that might have been formed. The liquid phosphorus was now in what is believed to be a hitherto unnoticed allotropic modification. Its peculiarity is that of retaining the liquid form indefinitely at temperatures very considerably below the melting point of ordinary phosphorus. A small portion in a test-tube solidified at 3·3° C. (38° F.). Another peculiarity is that it is not oxidized on exposure to the air, and consequently does not shine in the dark. (*A. J. P.*, March, 1874, p. 112; from the *Journal of the Franklin Institute.*)

decided enlargement, but if the patient live long enough it atrophies. Both in its symptoms and in its lesions phosphorus poisoning so closely resembles acute atrophy of the liver that only by detecting the phosphorus in the matters vomited, in the excretions, or in the tissues of the body, can a positive diagnosis be made. M. Poulet (*Gaz. Méd. de Paris*, Aug. 1872) states that hypophosphorous acid can be detected in the urine by heating the latter with nitric acid to dryness; if the acid be present, as the latter condition is approached there will be a sudden outburst of flame.

E. Mitscherlich gives the following as a delicate test for phosphorus. The suspected substance is distilled with sulphuric acid and water from a flask, by means of a tube bent twice at right angles, into a vertical cooling-tube, passing through the bottom of a wide glass cylinder filled with water, which is constantly kept cold by passing cold water in at the bottom, while the warm water escapes at the top. Under the cooling-tube is placed a vessel to receive the distillate. If phosphorus be present, its vapor, mixed with steam, distils over, and gives rise to a distinct luminous appearance, visible in the dark, at the point where it enters the cold part of the cooling-tube. The presence of alcohol and ether prevents the occurrence of the luminous appearance until they have distilled over. Oil of turpentine has the same effect permanently, but is not likely to be present in medico-legal cases. (*Am. Journ. of Med. Sci.*, July, 1856, p. 280; from the *Lancet*.) This test acts equally well in the presence of fatty matters, as has been shown by M. de Vrij. Roussin finds that the presence of free butyric acid prevents the luminous appearance of the phosphorus. After neutralization with potassium carbonate, however, it can be seen. (Sonnenschein, *Gerichtl. Chem.*, 1881, p. 27.) L. Hofmann gives the following method of detecting phosphorus in the viscera in cases of poisoning. The viscera, mixed with water and a little sulphuric acid, are distilled until two drachms of liquid are obtained; to this a few drops of ammonium sulphide (ammonium sulphydrate) are to be added, and the liquid is to be evaporated to dryness in a porcelain dish. If phosphorus be present in the minutest quantity, a drop of solution of ferric chloride will produce a deep violet and brownish, though evanescent, color. (*Chem. News*, Feb. 3, 1865, p. 53.) In addition to Mitscherlich's test, Dusart's is also used. This consists in passing pure hydrogen gas, evolved in a separate vessel, through the solution supposed to contain phosphorus, which solution has been previously warmed to about 50° C. The gas then is allowed to issue from a fine jet and is lighted. If phosphorus be present, the flame will show a green color in the centre.

The treatment of phosphorus poisoning consists simply in administering the antidotes as soon as possible. Oil of turpentine was originally proposed by Andant. After much discussion, it has been finally determined that, whilst the pure oil has no effect upon phosphorus, the acid French oil of European commerce forms with it a crystalline, spermaceti-like mass. This is soluble in ether, alcohol, and alkaline solutions, and has received the name of *turpentine-phosphoric acid*. It is said to be eliminated by the kidneys unchanged, and to exert no deleterious influence. Köhler asserts that when German oil has not been rectified for some time it acts upon phosphorus. He believes that the oil acts partly by oxidizing the poison, and partly by converting it into the harmless turpentine-phosphoric acid. One part of the oil must be given for 0·01 part of the phosphorus. The ordinary American oil of turpentine, as well as the Canada Balsam, appears to be of no antidotal value in phosphorus poisoning.

As was pointed out by MM. Eulenberg and Guttmann, phosphorus in a solution of a soluble salt of copper becomes black immediately, owing to the formation of a phosphide of the metal. Prof. Bamberger asserts that, whilst this change is very rapid, that induced by turpentine is a slow one, and, from an elaborate series of experiments upon animals, he concludes that copper is much the more valuable and certain antidote. Antal found potassium permanganate an antidote in acute poisoning by phosphorus. Dr. Hajinos has successfully washed out the stomach, half an hour after the ingestion of the poison, with a pint of a one-tenth-per-cent. solution of the permanganate. (*Notes on New Remedies*, July, 1892.) In human poisoning, copper sulphate should be given in dilute solution, three grains (0·20 Gm.) every five minutes until vomiting is induced. After this, if the French oil be accessible, it may be given freely in emulsion, or, probably better, a solution of potassium permanganate may be administered. Magnesium sulphate or citrate should be used as a quickly-acting purge, and symptoms met as they arise.

In dogs poisoned by phosphorus, MM. L. Orfila and Rigaut have shown that putrefaction was remarkably retarded. In a case of chronic poisoning from the copious inhalation of phosphorus vapor, the principal results were a gradual decay of the sexual function, and paralysis, terminating in death at the end of three years. Partial or general paralysis is a not uncommon result. (*Lancet*, July 7, 1866, 23.)

The dose of phosphorus is from $\frac{1}{100}$ to $\frac{1}{75}$ of a grain (0·0006–0·0008 Gm.). Much larger doses than these have been given, but have in various cases produced unpleasant symptoms. The *elixir* (*Elixir Phosphori*) is probably the most eligible of the liquid preparations; but the *oil* (*Oleum Phosphoratum*) is very efficient, as is also the official pill (*Pilulæ Phosphori.*) Great caution is necessary in the exhibition of phosphorus, and its effects should be closely watched. It ought never to be given in substance.*

PHYSOSTIGMA. U. S. (Br.) Physostigma. [Calabar Bean.]

(PHĬ-SO-STĬG'MĄ.)

"The seed of Physostigma venenosum, Balfour (nat. ord. Leguminosæ)." *U. S.* "The ripe seeds of Physostigma venenosum, Balfour." *Br.*

Physostigmatis Semen, *Br.;* Calabar Bean; Faba Calabarica, *P. G.;* Fève de Calabar, *Fr.;* Kalabarbohne, *G.;* Ordeal Bean of Calabar.

Physostigma venenosum. Balfour, *Trans. Roy. Soc. Edinb.*, xxii. 305; *Ed. Med. Journ.*, July, 1863, p. 34; *B. & T.* 80. This is a climbing plant, with a ligneous stem, mounting on trees and shrubs, and frequenting especially the banks of streams, into which it often drops its fruit when ripe; and it is said that the people of Calabar derive their supply principally from the borders of the streams down which the fruits are carried. The root is spreading, with numerous fibrils, often having attached to them small succulent tubers. The flowers are in axillary, multiflorous, pendulous racemes. The corolla is papilionaceous, of a pale-pink color, with a purplish tinge. The legume when ripe is about seven inches long, and contains two or three seeds. It ripens at all seasons, but is most abundant during the rainy season from June to September. The seeds are the part used. The plant, which is indigenous to Western Africa, has been introduced into India and Brazil, and is said to flourish in the latter country. Only one other species (*P. mesoponticum*, Taub.), also of tropical Africa, is known.

This bean was brought to the notice of the scientific public by Dr. Daniell, in 1846. Considerable attention was attracted to the subject, and specimens of the bean were obtained by Dr. Christison from the Gold Coast. These were planted in the Botanical Garden at Edinburgh, and produced a perennial creeper. In the year 1859, specimens of the plant were sent from Calabar, which came under the observation of Dr. Balfour, of Edinburgh, who was thus enabled to ascertain its botanical character.

Properties. The seed is about the size of a large horse-bean, being somewhat more than an inch in length by three-fourths of an inch in breadth, with a very firm, hard, brittle, shining integument of a brownish-red, pale-chocolate, or ash-gray color. The shape is irregularly kidney-form, with a longer convex and a shorter concave edge, two flat sides, and a furrow running longitudinally along its convex margin and ending in an aperture near one of the extremities of the seed. Within the shell is a kernel consisting of two cotyledons, weighing on an average about 46 grains, hard, white, pulverizable, odorless, and having a taste like that of the ordinary edible leguminous seeds, without bitterness, acrimony, or aromatic flavor. "About 25 to 30 Mm. long, 15 to 20 Mm. broad, and 10 to 15 Mm. thick; oblong, and somewhat reniform; testa granular, chocolate-brown, with a broad, black groove extending over the entire length of the convex edge; embryo with a short, curved radicle, and two large, white, concavo-convex cotyledons; inodorous; taste bean-like. On moistening the embryo with potassium hydrate test-solution, it becomes pale yellow." *U. S.* The bean yields its virtues to alcohol, and imperfectly to water. The shell constitutes, according to Dr. Edwards, 30 per cent., the kernel 70 per cent., of the bean. Jobst and Hesse (*Journ. de Pharm.*, Mars, 1864, p. 277) first isolated an active principle, which they found exclusively in the cotyledons. They obtained

* *J. Ashburton Thompson's Solution of Phosphorus.* Take of phosphorus, one grain (0·065 Gm.); absolute alcohol, five fluidrachms (18·4 C.c.). Dissolve the former in the latter by gentle heat, and add to it a previously warmed mixture of one and a half fluidounces (44·2 C.c. of glycerin, two fluidrachms (7·4 C.c.) of alcohol, and forty minims (2·5 C.c.) of spiritus menthæ piperitæ. One fluidrachm (3·75 C.c.) of this solution contains $\frac{1}{20}$ grain (0·003 Gm.) of phosphorus.

Tinctura Phosphori (*Bellevue Hospital*). Take of clean, transparent phosphorus, thirty-two grains (2·07 Gm.); absolute alcohol, forty-six fluidounces (1360 C.c.). Digest the phosphorus in the alcohol on a water-bath in a flask provided with a reflux condenser, until solution has taken place. Allow the solution to cool, and add to it one fluidounce (29·5 C.c.) of essence of vanilla, and three fluidrachms (11 C.c.) of oil of orange. Finally, make up the bulk with absolute alcohol to forty-eight fluidounces (1416 C.c.). Twelve fluidrachms (44·2 C.c.) of this solution contain one grain (0·065 Gm.) of phosphorus. (*N. R.*, April, 1876.)

Phosphorus Paste, for the destruction of vermin, is made as follows. Triturate six parts of phosphorus and one part of sulphur with six parts of water, until they liquefy. Then mix in two parts of flour of mustard, eight parts of sugar, and twelve parts of rye flour, with the aid of ten additional parts of water, and stir the whole so as to form a soft paste, which must be kept in pots closely stopped. (*A. J. P.*, 1855, p. 473.)

it by exhausting an alcoholic extract of the seeds with water, adding magnesia to neutralization, which is indicated by the liquid becoming brown, then concentrating, and treating with ether. The ethereal solution was shaken with a little weak sulphuric acid. The liquid separated into two layers,—the upper, ethereal, containing no alkaloid, and the lower, a solution of the sulphate in water. The latter was separated, treated with magnesia, and afterwards with ether, which yielded the alkaloid on evaporation. The substance thus obtained they proposed to name *physostigmine*. It was brown, amorphous, soluble in ammonia, soda, ether, benzol, and alcohol, and less so in cold water. In 1867, Hesse (*Ann. der Chem. Pharm.*, 141, 82) obtained the same alkaloid in a still purer state, perfectly colorless and tasteless, fusing at 45° C. (113° F.), and decomposing at 100° C. (212° F.) with red coloration. He gives it the formula $C_{15}H_{21}N_3O_2$. In 1865 Vée and Leven (*Comptes-Rendus*, 60, 1194) obtained, by treating the seeds in nearly the same manner, an alkaloid to which they gave the name *eserine*, which formed colorless tabular crystals of a bitter taste, readily soluble in ether, alcohol, or chloroform, but sparingly soluble in water. The crystals contain 1 molecule of water, which they lose at 100° C., and the anhydrous alkaloid then fuses at from 102°–103° C. The identity of this principle with the physostigmine of Hesse is now generally accepted. The solution of eserine acts quickly on the pupil, and a drop of a solution containing only 1 part in 1000, placed within the eyelids, causes great and lasting contraction. Of this alkaloid 1·5 milligrammes (·023 gr.) injected under the skin of a guinea-pig produced palsy of the hind legs in five minutes, and death in half an hour, with dilatation of the pupil at the moment of death. It is said to be capable of destroying life by absorption from the conjunctiva. A peculiarity of the alkaloid is that an aqueous solution of it, or of one of its salts, exposed to the air in the presence of potassa, soda, or lime, becomes red, owing to the absorption of oxygen. The coloring matter is taken up by chloroform. The color is not permanent, but gradually changes to yellow, green, or blue. This test will detect less than the hundred-thousandth part of the alkaloid. The same property is possessed by the alcoholic extract of the bean.* Physostigmine was official in the Br. Ph. 1885, and was thus described: "In colorless or pinkish crystals, slightly soluble in water, but readily soluble in alcohol and in diluted acids. The aqueous solution has an alkaline reaction, when warmed with or when shaken with dilute solution of potash becomes red, and when evaporated to dryness over a water-bath leaves a bluish residue, the acidified solution of which is beautifully dichroic, being blue and red."

Harnock and Witkowski in 1876 obtained still another alkaloid, which they named *calabarine*. It is soluble in alcohol and water, nearly insoluble in ether, melts at 132° C., and differs in physiological character from physostigmine. It is now generally known under the name of *eseridine*,† and the formula $C_{15}H_{23}N_3O_3$ given to it. This formula differs from that of physostigmine, it will be seen, by H_2O only, and it is stated that the one can be changed into the other by the action of dilute acids.

Hesse obtained also a neutral principle, *phytosterin*, by exhausting the cotyledons with petroleum ether. It is closely allied to cholesterin, but its chloroform solution is devoid of rotatory power. Its formula is $C_{26}H_{44}O + H_2O$, and its melting point is 133° C. (271·4° F.).

Medical Properties and Uses. Calabar bean has been used from time immemorial

* *Physostigmine or eserine sulphate* is obtained by M. A. Petit in the following manner. A hydro-alcoholic extract of the bean is dissolved in four parts of distilled water, and the solution filtered. To the solution is added one gramme of potassium bicarbonate for every 20 grammes of extract, and the mixture is shaken with ether in excess. The ether, which takes up nearly all the alkaloid, is, after a few minutes' repose, separated. A little distilled water is then added, and afterwards sulphuric acid drop by drop, the liquid being shaken after each drop, and tested with litmus paper till exactly neutral. After standing, the aqueous solution is separated from the ether, which now contains none of the alkaloid. This ether is then employed as before, and the operation repeated three or four times, so as completely to exhaust the original solution, and the liquid obtained each time is added to the last watery solution. This contains the physostigmine sulphate nearly pure. To purify this, it should be passed through the same process as the original solution of the extract. The resulting solution may be evaporated to crystallization if desired; but usually the evaporation is carried only so far as to get rid of all the ether present. If enough water be added to the solution to make as many grammes as there were drops of sulphuric acid (H_2SO_4) employed, each gramme will represent one centigramme (·1543 gr.) of the alkaloid. Of a collyrium made of one part of this to nine parts of water, a drop or two will be sufficient to act promptly on the pupil. (*N. R.*, April, 1872, 380.) Petit and Polonovski conducted experiments with the view of discovering salts of eserine which would be stable and non-hygroscopic; they made *eserine benzoate, eserine meta-cresotate, eserine citrate,* and *eserine tartrate.* Processes will be found in *Journ. Pharm. Chem.*, 1894, 55.

† Eseridine (*Deutsche Med. Zeit.*, Dec. 1889) is said to produce in the lower animals excitement with elevation of the blood-pressure and slowness of the pulse, followed by progressive paralysis and death from failure of the respiration. It is also affirmed to markedly increase internal peristalsis and to produce watery purging. It has been recommended by Eber, also by Ostertag (*Berlin. Thierärztl. Wochenschr.*, Jhrg. 4, 5, Nos. 40, 43), as a laxative in veterinary medicine, but has not been used to any extent in human beings. As a poison it is said to have one-sixth the strength of *eserine.*

by the natives of Africa as an ordeal, and, when given by their head men, usually proves fatal to the accused, unless free vomiting occurs. A draught containing 19 seeds pounded and infused in water is said to have killed a man in an hour. In the experiments of Dr. Fraser, it was found that the integuments of the seeds, as well as the shell, are distinctly purgative. It is probable that in the fresh bean they are also emetic, and that the priests or chiefs who administer the ordeal take advantage of this in regulating the effects of the poison to suit their own purposes; sometimes, however, even the pure alkaloid vomits. (*Gubler.*) Dr. Christison took about 12 grains of the kernel, which in fifteen minutes produced giddiness and a feeling of torpidity, followed by great weakness and faintness, paleness of the surface, extreme weakness and irregularity of the pulse, and indisposition or inability to make voluntary muscular effort. A peculiar epigastric sensation is often the first symptom of the action of the poison, and sometimes becomes severe. The heart often acts tumultuously or irregularly, but the pulse-frequency may be reduced. Of seventy children poisoned in Liverpool by eating Calabar beans which had been thrown out upon a waste-heap, vomiting occurred, or was produced by emetics, in all except one, in whom four kernels caused death. The nausea and vomiting came on in about half an hour, the nervous symptoms in less than an hour.

In the lower animals Calabar bean produces muscular tremors, diminished reflex activity, contractions of the pupils, some cardiac disturbance, and a progressive paralysis ending in death from paralytic asphyxia. It has been proved by Fraser that the paralysis is due to a depressant action upon the motor tract of the spinal cord, this being the most important physiological effect of the drug. The brain, the sensory tract of the cord, and the nerve-trunks are not affected, but the muscles are directly influenced: hence the muscular twitchings. Small doses somewhat increase the force but diminish the frequency of the heart-beat, and cause rise of arterial pressure. Toxic doses depress the heart and lower arterial pressure. The intestinal peristalsis, and probably also the bronchial movements, are primarily increased, and, after a toxic dose, secondarily diminished. Locally applied to the eye, Calabar bean causes myosis, with disturbance of accommodation. A similar effect is usually produced by large doses taken internally; it is largely the result of a local paralysis of the peripheral sympathetic fibres in the eye, but it is probable that there is also stimulation of the oculo-motor nerve terminations. The sedative influence of Calabar bean upon the motor spinal tract early led to its use in *tetanus*, *strychnine poisoning*, and similar conditions of spinal excitement. Clinical experience has, however, shown that it is of less value than chloral or some other depressant motors, so that it is chiefly employed as a succedaneum for these remedies. The effect of the drug upon intestinal peristalsis has led to its use in "*phantom tumor*" of the abdomen, *constipation*, and other *affections of the bowels* dependent upon muscular atony. It has also been employed with great asserted advantage in *chronic bronchitis*.

In Calabar bean poisoning the stomach should be thoroughly washed out, and atropine, which has been found by Kleinwächter, Bourneville, and Fraser to be physiologically antagonistic to Calabar bean, should be given hypodermically in doses of from one-sixtieth to one-fortieth of a grain (0·001–0·0015 Gm.), repeated at intervals according to the exigencies of the case. Strychnine would also probably be found useful. The best preparation of Calabar bean is the alcoholic extract, which, according to Dr. Fraser, is twenty-four times as strong as the kernel. Its maximum commencing dose may be set down as one-eighth of a grain (0·008 Gm.), representing three grains of the crude drug (0·2 Gm.). The alkaloid *eserine*, either in solution or in the form of gelatin disks containing definite quantities (from $\frac{1}{5000}$ to $\frac{1}{1000}$ of a grain), which are put in the eye, has entirely replaced the alcoholic extract as a local myotic.

PHYSOSTIGMINÆ SALICYLAS. U. S. Physostigmine Salicylate.

[Eserine Salicylate.]

(PHĪ-SŌ-STĬG-MĪ'NÆ SĂL-Ļ-CĪ'LĂS.)

$C_{15}H_{21}N_3O_2C_7H_6O_3$; 412.17. $C_{15}H_{21}N_3O_2C_7H_6O_3$; 413.

"The salicylate of an alkaloid prepared from Physostigma. It should be kept in small, dark amber-colored, well-stoppered vials." *U. S.*

This salt was introduced into the Pharmacopœia of 1880 in preference to the sulphate of the alkaloid (see page 1029) on account of its greater stability. Owing to the greater molecular weight of salicylic acid, the salicylate cannot be as effective as the sulphate in equal quantities, nor is it as soluble in water. Its advantage is that it is not deliquescent. Birkenwald (*Pharm. Zeit. f. Russ.*, 1891, 657) gives the following process. 100 parts of eserine sul-

phate are dissolved in a suitable quantity of water, and an excess of a solution of sodium bicarbonate added and agitated with several portions of absolute ether; the ethereal solutions are filtered into a beaker containing 35·5 parts of salicylic acid dissolved in ether, thoroughly mixed, and the eserine salicylate collected upon a filter, washed with absolute ether and dried, protected from sunlight and air. Any excess of salicylic acid that may have been present is removed by the washing with ether. The success of this method depends upon rapid manipulation and preventing exposure to sunlight, otherwise the salt obtained will be of a red color due to the decomposition of eserine and formation of *rubeserine;* washing the crystals with alcohol will remove any red color, but with loss of eserine salicylate. "Colorless or faintly yellowish, shining, acicular, or short, columnar crystals, odorless, and having a bitter taste. It acquires a reddish tint when long exposed to light and air. Soluble, at 15° C. (59° F.), in 150 parts of water, and in 12 parts of alcohol; in 30 parts of boiling water, and very soluble in boiling alcohol. When heated to about 179° C. (354·2° F.), the salt melts. Upon ignition, it is consumed, leaving no residue. The salt usually has a faintly acid reaction on litmus paper. On adding a small portion of the salt to colorless, concentrated sulphuric acid, the latter assumes a tint not deeper than yellow. If a minute portion of the salt be added to a few C.c. of ammonia water, in a small capsule, the liquid will acquire a yellowish-red color. On evaporating the liquid on a water-bath, a blue residue will be left which yields, with alcohol, a blue solution becoming violet-red upon supersaturation with acetic acid, and exhibiting a strong, reddish fluorescence. The aqueous solution of the salt, when mixed with ferric chloride test-solution, assumes a deep violet color." *U. S.*

Medical Properties. This salt has the medical properties of its base. The maximum first dose of physostigmine or its salts is one-thirtieth of a grain, to be increased as occasion demands. In the dose mentioned the alkaloid is a very valuable addition to a laxative pill, especially when the constipation is due to atony of the muscular coat of the intestines; but such pill must not be repeated in less than five hours. For ordinary ophthalmic purposes a solution of a quarter of a grain of the salt of physostigmine to the ounce is of sufficient strength, but in *glaucoma* and other severe diseases of the eyes the strength of two grains to the fluidounce is sometimes necessary. When a long-continued use of the drug is desired, one-sixteenth grain to the ounce is usually of sufficient strength. Physostigmine solution soon acquires a pinkish color, which deepens with age, but does not sensibly affect the action of the drug upon the eye.

PHYSOSTIGMINÆ SULPHAS. U. S., Br. Physostigmine Sulphate.

[Eserine Sulphate.]

$(C_{15}H_{21}N_3O_2)_2H_2SO_4$; 646·82. (PHĬ-SO-STĬG-MĪ'NÆ SŬL'PHĂS.)

"The sulphate of an alkaloid obtained from Physostigma. It should be kept in small, dark amber-colored and well-stoppered vials." *U. S.* "The sulphate, $(C_{15}H_{21}N_3O_2)_2,H_2SO_4,xH_2O$, of an alkaloid obtained from Calabar Bean." *Br.*

This is a new official salt: it is preferable to the salicylate on account of its greater solubility, but on exposure to the air it soon assumes an extractive consistence which renders it difficult to dispense; the salicylate is free from this objection.

"A white or yellowish-white, micro-crystalline powder; odorless, and having a bitter taste. It is very deliquescent when exposed to moist air, and gradually turns reddish by exposure to air and light. Very soluble in water and in alcohol, at 15° C. (59° F.), and still more so at the boiling temperature of these liquids. At 105° C. (221° F.), the salt melts, and upon ignition it is consumed, leaving no residue. The salt is neutral to litmus paper. On adding a small portion of the salt to colorless, concentrated sulphuric acid, the latter should not assume a tint deeper than yellow. If a minute portion of the salt be added to a few C.c. of ammonia water in a small capsule, the liquid will acquire a yellowish-red color. On evaporating this liquid on a water-bath, a blue or bluish-gray residue will be left which yields, with alcohol, a blue solution becoming violet-red upon supersaturation with acetic acid, and exhibiting a strong reddish fluorescence. The aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate, insoluble in hydrochloric acid." *U. S.* "When shaken with dilute *solution of potassium hydroxide* it becomes red; and when mixed with *solution of ammonia*, and evaporated to dryness on a water-bath, it leaves a bluish residue, the solution of which in very dilute acids is dichroic, being red by reflected and blue by transmitted light. A minute fragment dissolved in a few drops of *fuming nitric acid* yields a yellow liquid, which on evaporation on a water-bath darkens in color, the residue when completely dried being of a green color.

A dilute aqueous solution applied to the eye causes contraction of the pupil. It leaves no ash when burned with free access of air." *Br.*

The medical properties, uses, and dose are the same as those of *Physostigminæ Salicylas.*

PHYTOLACCÆ FRUCTUS. U. S. Phytolacca Fruit.

[Phytolaccæ Bacca, Pharm. 1880. Poke Berry.]

PHYTOLACCÆ RADIX. U. S. Phytolacca Root. [Poke Root.]

(PHĬ-TŌ-LĂC'ÇÆ RĀ'DĬX.)

"The root of Phytolacca decandra, Linné (nat. ord. Phytolaccaceæ)." *U. S.*

Racine de Phytolaque, *Fr.;* Kermesbeerenwurzel, *G.*

Phytolacca decandra. L. *Sp. Pl.* (1762) 631; Willd. *Sp. Plant.* ii. 822; Bigelow, *Am. Med. Bot.* i. 39; Barton, *Med. Bot.* ii. 213. This is an indigenous plant, with a large perennial root, often five or six inches in diameter, divided into two or three principal branches, soft, fleshy, fibrous, whitish within, and covered with a brownish cork. The stems, which are annual, frequently grow to the height of six or eight feet, and divide into numerous spreading branches. They are round, very smooth, green when young, but purple after the berries have ripened. The leaves are scattered, ovate-oblong, entire, pointed, smooth, ribbed beneath, and on short footstalks. The flowers are numerous, small, and in long racemes, which are sometimes erect, sometimes drooping. The corolla consists of five ovate, concave, whitish petals, folding inward. There are ten stamens and the same number of pistils. The raceme of flowers becomes a cluster of dark purple, almost black, shining berries, flattened above and below, and divided into ten cells, each containing one seed.

The poke is abundant in all parts of the United States, flourishing along fences, by the borders of woods, and especially in newly-cleared and uncultivated fields. The muck thrown up from the ditches of swamps is peculiarly favorable to it; and a bed of muck may almost always be recognized by the luxuriant growth of poke with which it covers itself. It also grows spontaneously in the north of Africa and the south of Europe, where, however, it is supposed to have been introduced from America. Its flowers begin to appear in July, and the fruit ripens in autumn. The magnitude of the poke-weed, its large rich leaves, and its beautiful clusters of purple berries, often mingled upon the same branch with the green unripe fruit and the flowers still in bloom, render it one of the most striking of our native plants. The young shoots are much used as food early in the spring, boiled in the manner of spinage. The ashes of the stems and leaves contain a very large proportion of potassa, yielding, according to Braconnot, not less than 4·2 per cent. of the pure caustic alkali. In the plant the potassa is neutralized by an acid closely resembling malic acid, though differing from it in some respects The leaves, berries, and root are used, but only the two latter are mentioned in the Pharmacopœia. The root is most active. It should be dug up late in November, cut into thin transverse slices, and dried with a moderate heat. As its virtues are diminished by keeping, a new supply should be procured every year. The berries should be collected when perfectly ripe, and the leaves about the middle of summer, when the footstalks begin to redden.

The *berries* contain a succulent pulp, and yield upon pressure a large quantity of fine purplish red juice. They have a sweetish, nauseous, slightly acrid taste, with little odor. They are officially described as "a depressed-globular, dark purple, compound berry, about 8 Mm. in diameter, composed of ten carpels, each containing one lenticular, black seed; juice purplish-red; inodorous; taste sweet, slightly acrid." *U. S.* The coloring principle is evanescent, and cannot be applied to useful purposes in dyeing, from the difficulty of fixing it. Alkalies render it yellow; but the original color is restored by acids. The juice contains saccharine matter, and, after fermenting, yields alcohol by distillation.

The *dried root* is branched, of a light yellowish-brown color externally, very much wrinkled, and, when in transverse slices, exhibits on the cut surface numerous concentric rings, formed by the projecting ends of fibres, between which the intervening matter has shrunk in drying. The structure internally in the older roots is firm and almost ligneous; the color yellowish white, alternating with darker circular layers. The fracture is fibrous, the wood-bundles in several distinct, concentric circles. There is no smell. The taste is slightly sweetish, and at first mild, but followed by a sense of acrimony. It is officially described as "large, conical, branched and

fleshy; mostly in transverse or longitudinal slices, wrinkled, grayish, hard; fracture fibrous, the wood-bundles in several distinct, concentric circles; inodorous; taste sweetish and acrid." *U. S.* The active matter is imparted to boiling water and alcohol. From the analysis of Mr. Edward Donnelly, the root appears to contain tannic acid, starch, gum, sugar, resin, fixed oil, and lignin, besides various inorganic substances. (*A. J. P.*, xv. 169.) Claussen (*Pharmacist*, 1879, p. 466) prepared from the seeds of *Phytolacca decandra*, by extraction with alcohol, evaporation to dryness, and taking up with chloroform or ether, after washing the residue with petroleum ether, a neutral principle in silky lustrous crystals, insoluble in water, soluble in alcohol, ether, and chloroform, which he named *phytolaccin*. A. Tereil (*Comptes-Rendus*, 91, 856) obtained from the berries an acid (*phytolaccic acid*) as an uncrystallizable yellowish-brown mass of gummy consistency. It was soluble in water and alcohol, slightly soluble in ether, of acid reaction, and gelatinizing with hydrochloric and sulphuric acids. W. F. Wagner (*A. J. P.*, 1887, p. 69) found tannin in the berries, but not in the root. W. A. Partee (*A. J. P.*, 1888, p. 123) made a proximate examination of poke root and found crystals deposited from a solution of an alcoholic extract in absolute alcohol; he also discovered traces of tannin, glucose, and indications which pointed to the presence of a glucosidal principle. Frankforter and Ramaley (*A. J. P.*, 1897, 281) have again analyzed the root with care. They find nearly 10 per cent. of a non-reducing sugar, free acid, identified as formic acid, but no certain proof of either alkaloid or glucoside. The very bitter resin amounted to 1 per cent.

Medical Properties and Uses. Poke is emetic, purgative, and somewhat narcotic. As an emetic it is very slow in its operation, frequently not beginning to vomit in less than one or two hours after it has been taken, and then continuing to act for a long time upon both the stomach and the bowels. The vomiting produced by it is said not to be attended with much pain or spasm; but narcotic effects have been observed by some physicians, such as drowsiness, vertigo, and dimness of vision. In overdoses it produces excessive vomiting and purging, attended with great prostration of strength, and sometimes with convulsions. A woman (*Stethoscope* for March, 1852, ii. 134) ate a double handful of the berries. Free purgation followed upon the first day, after which coma set in, with great prostration, though death did not occur until after the sixth day. A child, six years old, after having swallowed two or three fluidrachms of a tincture of the root, was seized in less than an hour with tonic spasm of the muscles, the extremities being stiff, the hands clinched, the feet extended and toes flexed, and the trunk in a condition of opisthotonos. (*Atlanta Med. and Surg. Journ.*, July, 1866.) According to Prof. Roberts Bartholow, poke causes in the lower animals convulsions and death from paralysis of respiration. It is not fit for use as an emetic, but has been employed as an alterative with asserted good results in the treatment of *chronic rheumatism*, *granular conjunctivitis*, and even *cancer*. Locally it has been used in the form of ointment (a drachm to the ounce) in the treatment of *psora*, *tinea capitis*, *sycosis*, and *favus*. It occasions at first a sense of heat and smarting in the parts to which it is applied. The dose of the powdered root, as an emetic, is from ten to thirty grains (0·65–1·95 Gm.); as an alterative, from one to five grains (0·065–0·33 Gm.). A saturated tincture of the berries may be given in rheumatic cases, in the dose of a fluidrachm (3·75 C.c.), three times a day. Alcohol, diluted alcohol, and water extract the virtues of poke root.

PICROTOXINUM. U. S., Br. Picrotoxin.

$C_{30}H_{34}O_{13}$; **600·58.** (PĬC-RŌ-TŎX-Ī'NŬM.)

"A neutral principle obtained from the seed of Anamirta paniculata, Colebrooke (nat. ord. Menispermaceæ)." *U. S.* "A neutral principle obtained from the fruits of Anamirta paniculata, Colebr." *Br.*

This substance is obtained from Cocculus indicus, for an account of which see PART II. The formula $C_{15}H_{16}O_6+H_2O$ which is often given for picrotoxin belongs, according to Paterno and Oglialoro (*Gazz. Chim.*, ii. 41), to *picrotoxinin*, which with *picrotin*, $C_{15}H_{18}O_7$, is a decomposition product of the original picrotoxin, $C_{30}H_{34}O_{13}$. Picrotoxin is thus described: "Colorless, flexible, shining, prismatic crystals, or a micro-crystalline powder, odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 240 parts of water, and in 9 parts of alcohol; in 25 parts of boiling water, and in 3 parts of boiling alcohol; also soluble in solutions of the alkalies, and in acids. Very slightly soluble in ether or chloroform. Picrotoxin is neutral to litmus paper. When heated to 200° C. (392° F.), Picrotoxin melts, forming a yellow liquid, and upon ignition it is consumed, leaving no residue. Concentrated sulphuric acid dissolves Picrotoxin with a golden-yellow color, very gradually changing to

reddish-brown, and showing a brown fluorescence. On mixing about 0·2 Gm. of powdered sodium nitrate with 3 or 4 drops of sulphuric acid, in a small, flat-bottomed capsule, sprinkling a minute quantity of Picrotoxin over it, and then adding, from a pipette, concentrated solution (1 in 4) of sodium hydrate, drop by drop, until it is in excess, the particles of Picrotoxin will acquire a brick-red to deep red color which fades after some hours. On diluting 2 C.c. of alkaline cupric tartrate volumetric solution with 10 C.c. of water, and adding a small portion of Picrotoxin, red cuprous oxide will be separated within half an hour at ordinary temperatures, and much more rapidly upon the application of heat. The aqueous solution of Picrotoxin should remain unaffected by mercuric or platinic chloride test-solution, tannic acid test-solution, mercuric potassium iodide test-solution, or other reagents for alkaloids (absence of *alkaloids*)." *U. S.* "It melts at 378° F. (192·2° C.). It is soluble in 330 parts of cold or 35 of boiling *water*, and in 13 of cold or 3 of boiling *alcohol* (90 per cent.). It is soluble in 10 parts of *solution of potassium hydroxide*, and the resulting liquid, on boiling, immediately reduces *Fehling's solution*. Heated on platinum foil, the crystals melt, forming a yellowish liquid, which, on further heating, becomes charred, and is at length completely dissipated. It dissolves in *sulphuric acid* with a saffron-yellow color. Its aqueous solution is not precipitated by *test-solution of mercuric chloride*, *solution of platinic chloride*, or *solution of tannic acid* (distinction from alkaloids)." *Br.* E. Schmidt and Löwenhardt, who have made the most recent study of picrotoxin (*Ber. der Chem. Ges.*, xiv. 812), find with it several principles. They identify the easily soluble body *picrotoxinin*, $C_{15}H_{16}O_6$, fusing point from 200°–201° C., and the difficultly soluble anhydrous *picrotin*, $C_{15}H_{18}O_7$, fusing point from 240°–245° C. Picrotoxinin shows a brick-red color with the Langley reaction (see foot-note),* while picrotin is indifferent in this case. To procure it, the aqueous extract of the seeds is triturated with pure magnesia, and then treated with hot alcohol, which dissolves the picrotoxin, and yields it upon evaporation. In this state, however, it is impure. To obtain it colorless it must be again dissolved in alcohol, and treated with animal charcoal. After filtration and due evaporation, it is deposited in the crystalline form. Accompanying the picrotoxin in the seeds is *anamirtin*, $C_{19}H_{24}O_{10}$. Possibly identical with this is the *cocculin* of Löwenhardt, to which, however, the formula $C_{19}H_{26}O_{10}$ is given by its discoverer. It does not give any color with the Langley reaction. Besides picrotoxin, Cocculus indicus contains a large proportion of fixed oil, and other substances of less interest. In the shell MM. Pelletier and Couërbe discovered two distinct principles,—one alkaline and named *menispermine*, $C_{18}H_{24}N_2O_2$, the other identical with it in composition, but distinguishable by its want of alkalinity, its volatility, and its solubility and crystalline form, and denominated *paramenispermine*. They found also in the shell a new acid, which they called *hypopicrotoxic*. The picrotoxin of M. Boullay they believed to possess acid properties, and proposed for it the name of *picrotoxic acid*. (*Journ. de Pharm.*, xx. 122.)

Medical Properties. Picrotoxin is a violent poison to all classes of animals, producing when in sufficient dose violent convulsive attacks, both epileptic and tetanic, with periodic arrest of respiration, slowing of the heart-beat, and finally death. An almost characteristic phenomenon is the interchange between tonic and clonic convulsions, with a peculiar almost purposive movement in the clonic attacks: the motions of swimming, of walking, of rotation, of eating, etc., are usually some or all of them present. Vomiting sometimes occurs; the pupils are usually primarily contracted, secondarily dilated; and stupor deepens finally into coma. The convulsive movements are largely due to intense excitement of the motor cells in

* In Europe, picrotoxin is said to be added to malt liquors in order to give them bitterness and intoxicating properties,—although the practice is forbidden by law, in England, under heavy penalties. Gunckel proposes the following mode of detecting and separating picrotoxin from liquids containing it, founded on the facts that it is soluble in dilute acids though not combining with them, and that ether extracts it from its acidulous solutions, but not from those in water or alcohol, even with the presence of potassa. The substance suspected to contain it, having been brought to the consistence of paste, is to be digested with alcohol and a little tartaric acid, the liquid separated, the alcohol evaporated, the residue diluted with a little water and then treated with ether, and, finally, the ethereal solution submitted to evaporation in a watch-glass. Picrotoxin, if present, is deposited, recognizable by its feathery crystallization, its bitter taste, and the property of reducing the tartrate of copper and potassium. If strychnine, which perhaps resembles it most closely in its effects, is present, it will be left behind in the acidulated solution. (*Journ. de Pharm.*, 1858, p. 78; from *Archiv der Pharm.*, xciv. 14.) In the instance of adulterated malt liquor, in consequence of the resin of hops it contains, it might be expedient first to evaporate the liquor to dryness, and prepare a watery extract of the residue, and then to proceed as stated. Mr. J. W. Langley proposes, as a means of detection, the oxidation of picrotoxin. When to a little of this substance, mixed with potassium nitrate in a watch-glass, a drop of sulphuric acid is added, no observable reaction takes place; but, if a very strong solution of caustic potassa or soda be now added, a bright reddish-yellow color will be produced, which will be highly characteristic. A very minute quantity may thus be detected. Mr. Langley, however, thinks it probable that this phenomenon is owing to a minute quantity of some nitrogenous principle; for if picrotoxin be purified by combining it in solution with potassa, and then precipitating it with an acid, it does not answer the test. (*Am. Journ. of Sci. and Arts*, 1862.)

the medulla and spinal cord. The respiratory centres as well as the vaso-motor centres share in this action, the condition of excitement being probably followed in fatal cases by one of secondary depression and exhaustion. During the period of convulsion the reflex activity is often abated, especially directly after a convulsive attack. This, taken with the fact that section of the cord high up at such period brings on return of reflex activity, has led to the conclusion that the drug powerfully stimulates Setschenow's centre and thereby arrests reflex movement. The experiments of Gottlieb, however (*Arch. f. Exp. Path. u. Pharm.*, Bd. xxx., 1892), seem to show that small doses increase reflex activity by stimulating the motor cells, and he believes that the apparent loss of reflex activity after large doses is the result of exhaustion due to the motor discharges,—the return of the reflex activity after section of the cord being due to the arrest by such section of the convulsive attacks, and consequent prevention of exhaustion. This does not, however, seem probable, and, as asserted by Kóssa (*S. J.*, Sept. 1894), the motor tract of the medulla and spinal cord is probably in the end paralyzed by the poison. Small doses of picrotoxin have a very pronounced influence in increasing the blood-pressure, which increase seems from the experiments of Gottlieb to be chiefly due to excitement of the vaso-motor centres. The slowing of the heart produced by picrotoxin is largely owing to the extreme irritation of the inhibitory centres, but it would seem also that the poison has an influence directly upon the heart itself, since Falck has noted immediate slowing and quick arrest of the isolated frog's heart when picrotoxin solution is brought in contact with it. The final arrest of the heart is in diastole. According to Kóssa, the motor nerves and the voluntary muscle are not affected by the poison, which produces, however, violent peristalsis in the uterus and the intestinal tract.

In man, picrotoxin acts as it does in the lower animals, and a number of cases of serious or even fatal poisoning have been produced by it or by substances containing it. Planat commends it highly in *epilepsy*, *hystero-epilepsy*, *chorea*, and similar nervous disorders; and Dujardin-Beaumetz states that he has found it very useful in epilepsy in ascending doses of from one-quarter to three milligrammes. It has also been used with alleged excellent results in *night-sweats*, especially by Semmola. There seems to be little reason for believing it to be of value in practical medicine, but the experiments of Dr. M. Koppen (*Arch. für. Exper. Path. und Pharm.*, xxix., 1892) indicate that it is an active physiological antidote to poisons of the chloral group. In Kóssa's experiments (*Ungar. Arch. f. Med.*, i., 1892) it was found to increase the toxic action of morphine. Dose, from $\frac{1}{100}$ to $\frac{1}{30}$ of a grain (0·0006–0·0022 Gm.).

PILOCARPINÆ HYDROCHLORAS. U. S. Pilocarpine Hydrochlorate.

$C_{11}H_{16}N_2O_2HCl$; 243·98. (PĪ-LŌ-CÄR-PĪ'NÆ HĪ-DRŌ-ȻHLŌ'RĂS.) $C_{11}H_{16}N_2O_2HCl$; 244·4.

"The hydrochlorate of an alkaloid obtained from Pilocarpus. It should be kept in small, well-stoppered vials." *U. S.*

This alkaloidal salt is usually obtained by the process given under Pilocarpus for the alkaloid (see page 1034). Although the nitrate is more frequently found in commerce at present, the hydrochlorate has been preferred, principally because of its more ready solubility in water. Schuchardt notices (*N. R.*, May, 1881) that 100 parts of boiling water dissolve 66 parts of pilocarpine hydrochlorate, and water at 15° C. (59° F.) dissolves nearly the same amount; of alcohol of sp. gr. 0·820 it requires 7 parts for solution at 15° C. (59° F.), while the same alcohol, boiling, easily dissolves 2½ parts of the salt. According to the same authority, pilocarpine nitrate is soluble at 15° C. (59° F.) in 8 parts of water. At 100° C. (212° F.) it has the same solubility as the hydrochlorate. It requires 130 parts of alcohol of sp. gr. 0·820 at 15° C. (59° F.), and 40 parts of boiling alcohol, to dissolve it.

Pilocarpine hydrochlorate is officially described as in "small, white crystals, odorless, and having a faintly bitter taste; deliquescent on exposure to damp air. Very soluble in water and in alcohol; almost insoluble in ether or chloroform. When heated to 197° C. (386·6° F.), the salt melts, and upon ignition it is consumed, leaving no residue. The aqueous solution (1 in 100) of the salt is neutral, or has a faintly acid reaction upon litmus paper. Concentrated sulphuric acid dissolves the salt to a colorless liquid, with evolution of hydrochloric acid vapor. If a small fragment of potassium dichromate be added to a few drops of this solution, on a white porcelain surface, the dichromate will gradually dissolve with a vivid dark-green color. Fuming nitric acid dissolves the salt with a faintly greenish tint. The aqueous solution (1 in 100) of the salt is precipitated by iodine test-solution, bromine water, mercuric chloride test-solution, and most other reagents for alkaloids. If the aqueous solution be slightly acidulated, the subsequent addition of ammonia water will produce no precipitate. Sodium hydrate test-

solution produces a precipitate only in a concentrated solution of the salt. The aqueous solution yields with silver nitrate test-solution a white precipitate insoluble in nitric acid." *U. S.*

Medical Properties and Uses. Pilocarpine is superior to jaborandi (see *Pilocarpus*) in the certainty of its diaphoretic action, and in being less disagreeable, and probably less apt to nauseate. Weber, Bardenhewer, and Auschmann agree that 0·3 of a grain of it are equal to seventy-five grains of the best leaves; but this is probably an overestimate of its powers. The hydrochlorate may be used hypodermically in aqueous solution; the commencing dose is an eighth of a grain (0·008 Gm.), although much larger doses are sometimes necessary. A solution of the salt is sometimes used by oculists as a myotic. Pilocarpine is often used with advantage for the stimulation of other secretions than those of the skin. M. Cheron affirms that it is an active galactagogue. When given in doses of from one-fifteenth to one-twentieth of a grain (0·004–0·0032 Gm.), at intervals of two or three hours, it frequently acts as a powerful hydragogue diuretic. According to Watowski and others, it is of value in the treatment of *catarrhal jaundice*. In the form of gelatin disks (each containing from one-twelfth to one-fifteenth of a grain), allowed to dissolve slowly in the mouth, it has been used with alleged satisfaction against the excessively dry mouth of *phthisis* and other chronic diseases.

PILOCARPINÆ NITRAS. Br. Nitrate of Pilocarpine.

$C_{11}H_{16}N_2O_2HNO_3$. (PĪ-LŌ-CĂR-PĪ'NÆ NĪ'TRĂS.)

"The nitrate of an alkaloid, $C_{11}H_{16}N_2O_2,HNO_3$, obtained from Jaborandi Leaves." *Br.*

The Br. Ph. recognizes the *nitrate*, which it describes as "a white crystalline powder; soluble in 8 or 9 parts of cold *water;* slightly soluble in cold, freely soluble in hot *alcohol* (90 per cent.). Strong *sulphuric acid* forms with it a yellowish solution which, on the addition of *potassium bichromate*, gradually acquires an emerald-green color. A dilute aqueous solution applied to the eye causes contraction of the pupil. It leaves no ash when burned with free access of air (absence of mineral impurity)." *Br.* The medical properties and dose are the same as those of *Pilocarpinæ Hydrochloras.*

PILOCARPUS. U. S. (Br.) Pilocarpus. [Jaborandi.]

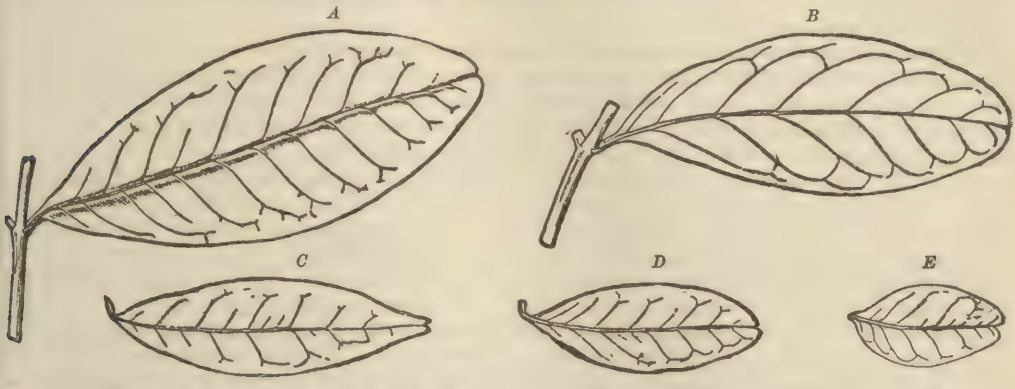
(PĪ-LŌ-CĂR'PŬS.)

Jaborandi Folia, *Br.*, Jaborandi Leaves; Pilocarpi Foliola; Folia Jaborandi, *P. G.*

"The leaflets of Pilocarpus Selloanus, Engler (Rio Janeiro Jaborandi), and of Pilocarpus Jaborandi, Holmes (Pernambuco Jaborandi) (nat. ord. Rutaceæ)." *U. S.* "The dried leaflets of Pilocarpus Jaborandi, Holmes." *Br.*

The words *jaborandi*, *iaborandi*, and *jamborandi* are used in Brazil in a generic sense to designate various pungent, sudorific plants. Among the chief of these are *Piper nodosum*, *P. citrifolium*, and *P. reticulatum*. The leaves of the *Piper jaborandi* are indeed sometimes sent into European commerce as jaborandi. There are some thirteen species of the genus Pilocarpus found in tropical America.

Under the name of jaborandi Dr. Coutinho (*Journ. de Pharm.*, 4e sér., xx. 51) introduced to the notice of the European profession a pinnately-leaved species belonging to the genus Pilocarpus. The pinnately-leaved species of this genus are divided by Martius (*Flora Brasiliensis*) into two sets: *A*, those in which the leaves are smooth on both sides; *B*, those in which the leaves on the under side, and especially on the nerves, are short-pilose.



The jaborandi leaves of commerce are usually smooth on both sides. The species of the smooth-leaved division, according to Martius and Engler and Prantl, which grow in Brazil, are *P. selloanus** and *P. pennatifolius* Lem., in which the leaves are two- or three-jugate, and *P. grandiflorus*, in which the leaves are six-jugate. *P. selloanus*, which is found in Southern Brazil, Paraguay, and Uruguay, has the flower-stalk six times as long as the flower-bud; whereas *P. pennatifolius* Lem., which occurs in the Brazilian provinces Matto Grosso and Cuyabá, possesses a flower-stalk that is but from three to four times as long as the flower-bud. It seems certain that little or none of the jaborandi of commerce comes from *P. grandiflorus*, and it would appear, therefore, that the Rio Janeiro jaborandi is the product of *P. selloanus*.

P. pennatifolius is the species to which the U. S. Pharmacopœia formerly referred jaborandi. In the original specimens of jaborandi seen by Dr. Coutinho, and also in other specimens received from the doctor's family by Surgeon F. V. Greene, U.S.N., some of the leaves are

* For translation of Martius's specific description, see *P. J. Tr.*, v. 641.

hairy, although most of them are smooth; and it seems probable that the species does contribute somewhat to the jaborandi of commerce.

Pernambuco jaborandi differs sufficiently from that of Rio Janeiro to indicate a probability of different origin; an examination of a flowering branch of the Pernambuco plant growing in the Botanical Garden at Cambridge led Mr. E. M. Holmes to the conclusion that it is an undescribed species, for which he proposes the name of *P. jaborandi*. He states (*P. J. Tr.*, xxii. 875) that it differs from *P. selloanus*, to which it is most nearly allied, in the elliptic-oblong shape of the leaflets and their more fleshy consistence, in the veinlets being more prominent on the upper surface, in the slender glabrous pedicels, only three times longer than the leaf-buds, in the minute bracts being situated near the apex of the pedicel, in the rose color of the ovate petals, pedicels, and upper part of the rachis, and in the rugose crenate disk. The calyx is pentagonal, not lobed. (See also *P. J. Tr.*, lv.)

A, leaflet of Pilocarpus pennatifolius; *B*, leaflet of P. selloanus; *C*, leaflet of P. microphyllus; *D* and *E*, leaflets of P. spicatus. All two-thirds natural size. (After Holmes.)

Properties. The following description of the drug is adapted from that of Dr. F. V. Greene, U.S.N., who had unquestionable specimens of the original jaborandi of Coutinho. The package contained several stems branched at an angle of about 20°, these branches being furnished with alternate leaves, which are impari-pinnate, with from two to five opposite leaflets (Planchon has met with leaves having as many as seven, nine, and, more rarely, eleven leaflets) articulated to the rachis by short petiolules, thickened at the base. The leaflets, which are coriaceous in texture, vary considerably in size and outline. As a rule, they may be considered as oblong-lanceolate, and are entire, emarginate, with an unequal base. The midrib rises very little above the upper surface of the leaflet, but is very prominent and sharp on the lower. The veins, which are rather more prominent on the lower surface, leave the midrib at an angle of about 60°, pursue a parallel course across the leaflet, and finally turn up and anastomose within about a quarter of an inch of the margin. The leaflets are pellucidly punctate; the dots are the receptacles of secretion, are numerously and irregularly distributed over the whole surface, and are plainly visible when the leaflet is held up to the light.* The fruit consists of five carpels, of which not more than two or three are usually developed to maturity; when ripe, the carpels dehisce into two valves, and then remind one strongly of miniature cockle-shells with the valves open exposing the animals. The black, shining, reniform seeds (one for each carpel) have a lancet-shaped hilum, a sharp ridge on the back near the apex, and a smooth, pale-yellow endocarp surrounding it. The official description of the drug is as follows. "About 10 to 15 Cm. long, and 4 to 6 Cm. broad, short-stalked, oval or ovate-oblong, entire and slightly revolute at the margin, obtuse and emarginate, unequal at the base; dull green, coriaceous, pellucid-punctate, mostly smooth; when bruised, slightly aromatic; taste somewhat bitter and pungent." *U. S.* The pellucid punctations are due to numerous oil glands embedded in the mesophyll. There are in commerce at present two chief forms or varieties of jaborandi, one coming from Pernambuco and one from Rio Janeiro. They are to be distinguished principally by their venation, though the leaves of the Rio Janeiro variety are more obovate in outline than the others. In the Pernambuco variety the veins upon the upper

* According to M. Conroy, the leaflets yield 0·76 per cent., the leafstalks only 0·37 per cent. of alkaloid.

surface are very prominent, which is not the case in the Rio Janeiro drug. Pernambuco jaborandi is said to be much richer in alkaloid.

Paraguay jaborandi is an inferior variety of the drug, which reaches European commerce from Buenos Ayres and from Rio Janeiro, and is believed to be collected in Paraguay. The leaves are thinner than those of the Pernambuco jaborandi, and have only two or three, never four, pairs of leaflets. It is also noticeable in the Paraguay variety that the lateral veins are not prominent, that the base is so tapered that the widest portion is above the middle, and that the upper surface is grayish green. This jaborandi was referred by Holmes to *P. pennatifolius*, but as the Paraguay leaflets differ somewhat among themselves, it is probable that they are the product of two or more species.

Maranham, or *small jaborandi* of writers, is at once distinguished from the other varieties by the smallness of its leaves, and though it was at one time supposed to be the product of a Zanthoxylum, appears to be yielded by a previously unknown Pilocarpus, to which Dr. Stapf has given the name of *P. microphyllus*.

In 1894 still another variety appeared in the London market under the name of *Ceará jaborandi*. It differs from those previously known by the dark brownish-green tint of the upper and the yellowish tint of the under surface of the leaflet, and by the under surface being covered with short hairs. According to E. M. Holmes, the plant that yields it is a new species of Pilocarpus, to which he gave the name of *P. trachylophus*.

All of the older varieties of jaborandi are yielded by pinnate-leaved species of Pilocarpus, but in 1895 a papery, rather rigid, lanceolated, brittle leaf, of a dark, rather brownish green above, and a rather paler hue beneath, attached to a short twisted petiole, came into commerce under the name of *Aracati jaborandi*.* It has been doubtfully referred to *P. spicatus*.

Chemical Constituents. An alkaloid was isolated in 1875 from jaborandi almost simultaneously by A. W. Gerrard and M. Hardy. To this the name of *pilocarpine* was given. Gerrard at the same time stated that there were at least two alkaloids in the leaves, and this view seemed to be confirmed when *jaborine* was discovered. He also obtained a volatile oil, tannic acid, a peculiar volatile acid, and potassium chloride. *Pilocarpine* may be prepared as follows. The leaves are exhausted with 80-per-cent. alcohol containing 8 grammes of hydrochloric acid in a liter, the tincture is distilled and evaporated to the consistence of a liquid extract, and this is mixed with a small quantity of water, and filtered. The filtrate is treated with a slight excess of ammonia, and then with a large quantity of chloroform. The chloroform solution is agitated with water, to which hydrochloric acid is added, drop by drop, in sufficient quantity to neutralize the alkaloid, the hydrochlorate of which is obtained in long needles on evaporating the aqueous solution, while foreign principles remain dissolved in the chloroform. By dissolving the crystals in water, treating the solution with ammonia and chloroform, and evaporating the latter solution, pilocarpine is obtained as a soft viscous mass, which is only slightly soluble in water, but is freely soluble in alcohol, ether, and chloroform. Kingzett assigned to pilocarpine the formula $C_{23}H_{34}N_4O_4 + 4H_2O$. Harnack and Meyer, on the other hand, give it as $C_{11}H_{16}N_2O_2$. The latter was generally accepted, and is recognized by the U. S. Pharmacopœia. It is now definitely established as correct by the synthesis of pilocarpine afterwards effected by Hardy and Calmels. (*Comptes-Rendus*, 105, pp. 68–71; also *A. J. P.*, 1887, p. 632.) By the action of hydrochloric acid or of barium hydrate, pilocarpine, $C_{11}H_{16}N_2O_2$, is changed into *pilocarpidine*, $C_{10}H_{14}N_2O_2$, by the loss of a methyl group. Now Hardy and Calmels have converted β pyridine—α lactic acid, into pilocarpidine, the methiodide of which by oxidation is converted into pilocarpine. The synthetical pilocarpidine and pilocarpine yield gummy derivatives similar to those obtained by Harnack and Meyer from the natural products. The physiological action of synthetical pilocarpine is identical with that of the natural alkaloid. Knudsen, E. Merck, and Petit and Polonovski all dispute the conclusions of Hardy and Calmels, and state that they failed to get pilocarpine by the synthetic method of these investigators. (*Proc. A. P. A.*, 1897, 716.) Petit and Polonovski (*Journ. de Pharm.*

* It may be of interest to mention here the relative percentage of alkaloids in the foregoing varieties, according to E. M. Holmes. (*P. J. Tr.*, lv.):

Jaborandi.	Per cent.
Pernambuco (*P. jaborandi*)	0·5 to 0·8 pilocarpine nitrate.
Paraguay (*P. pennatifolius*, etc.)	0·18 to 0·19 pilocarpine nitrate.
Maranham (*P. microphyllus*)	0·16 to 0.19 pilocarpine nitrate.
Maranham (*P. microphyllus*)	up to 0·8 alkaloidal nitrate.
Ceará (*P. trachylophus*)	0·02 new alkaloid (?).
Aracati (*P. spicatus ?*)	uncertain.

(See also *Proc. A. P. A.*, 1895, 266.)

(6), v. 481) obtained *pilocarpic* and *pilocarpidic acids* from pilocarpine and pilocarpidine. Harnack and Meyer first stated that *jaborine* is easily formed from pilocarpine, and may be produced by simply heating the latter alkaloid. They also showed that *pilocarpine* has physiological effects analogous to those of *nicotine*, whilst *jaborine* resembles *atropine* in its effects. Hardy and Calmels (*Journ. Chem. Soc.*, Sept. 1886, 815) state that pure, dry pilocarpine does not yield *jaborine* when heated at 100° C. for six hours, neither can this substance be obtained by the action of alcoholic iodides upon argento-pilocarpidine. If, however, carefully dried pilocarpine be heated rapidly to 175° C., kept at this temperature for about half an hour, and the product extracted with water made alkaline with baryta and shaken with ether, the ether will contain jaborine, the aqueous solution will contain pilocarpidine and *jaboric acid*. *Jaborine* separates from alcohol or ether in a brown mass, which changes to a brittle resinous solid. Its composition is considered to be $C_{22}H_{32}N_4O_4$; it has exactly twice the molecular formula of pilocarpine. It is insoluble in water, but dissolves readily in ether, and is soluble in jaboric acid. *Jaboric acid*, $C_{19}H_{25}N_3O_5$, is separated from pilocarpidine by precipitating with excess of silver nitrate, which forms a curdy precipitate of the composition $C_{19}H_{24}N_3O_5,AgNO_3$. Jaboric acid resembles jaborine in appearance, but is very soluble in water, and is not removed from its aqueous solution by ether.* Pilocarpine combines with acids, and a number of the salts are to be had in commerce. The nitrate has probably been used most frequently, although the hydrochlorate is now official. Gerrard tested the solubilities of several of the salts as follows. The *nitrate* is soluble in water, sparingly in cold but freely in boiling alcohol; it is insoluble in chloroform, benzol, carbon disulphide, and ether. The *phosphate* is soluble in water, sparingly in cold, more freely in boiling alcohol, from which on cooling it crystallizes in lustrous tables; it is insoluble in ether, chloroform, benzol, and carbon disulphide. The *hydrochlorate* is freely soluble in water, alcohol, and chloroform; insoluble in ether, benzol, and carbon disulphide. The *acetate* is soluble in water, alcohol, chloroform, benzol, and ether; insoluble in carbon disulphide. The *hydrobromate* is soluble in water, alcohol, and chloroform; insoluble in ether and carbon disulphide.

An essential oil of sp. gr. 0·875, and boiling between 180° and 290° C., has been obtained by Schimmel & Co., in Leipsic. (*Bericht*, April, 1888.) The portions going over above 260° C. solidified on cooling, and yielded a solid paraffin-like substance, which fuses at 27°–28° C. The oil amounts altogether to 0·4 per cent. In their latest report (Oct. 1893) they give as a probable constituent of the lower boiling portions of the oil *dipentene*, $C_{10}H_{16}$.

Medical Properties and Uses. When an infusion of from sixty to ninety grains of jaborandi is given to an adult, in about ten minutes the face and neck become deeply flushed, and free perspiration and salivation commence. After a hypodermic injection of the alkaloid, the symptoms may set in in six minutes. The sweating begins on the face; both it and the salivation are excessively profuse, and last from three to five hours. There is frequently nausea, and sometimes vomiting. The pulse is generally more or less quickened, as is also usually the respiration. After the sweating has ceased, the patient is left more or less exhausted. The nasal and lachrymal secretions are very generally increased under the action of the drug, and M. Gubler has noted diarrhœa. There is sometimes contraction of the pupils, and even disturbance of vision. These effects of the drug are in the adult fairly constant; but subjects have been occasionally found who were not susceptible to the action of the remedy, and, very curiously, in Dr. Ringer's experiments children were found to be very insusceptible, although doses of sixty grains were employed. Schwann and subsequent observers have noticed in the lower animals that very violent intestinal peristalsis is produced by the drug. The sweat produced by jaborandi is often enormous in quantity (from nine to fifteen ounces by estimation). It is stated to be at first acid, then neutral, and finally often clearly alkaline, as is also the saliva. Not only the watery but also the solid portions are increased, and the elimination of urea is said especially to be affected. Usually, but not always, when the drug acts very moderately upon the skin the salivary glands are but slightly affected, and *vice versa*. The cause of the excessive secretion is a direct action upon either the gland cells or the peripheral nerve-endings, most probably upon the former. In the first stages of sweating the bodily temperature sometimes rises, but it usually falls after the sweating.

When applied to the eye, pilocarpine produces great contraction of the pupil, tension of the accommodative apparatus, and an approximation of the nearest and farthest points of distinct vision by a peripheral action. It is stated to produce less irritation than Calabar bean.

* According to the researches of E. Harnack, *pilocarpidine* acts upon the animal organism in the same way as pilocarpine, but is somewhat less powerful.

Jaborandi is the most reliable and powerful of the diaphoretics. In *dropsies* it has been widely employed, and certainly is a most efficient remedy. Great value has been ascribed to it in facilitating the removal of local watery effusions, such as occur in *pleurisy* and *pulmonic œdema*. In *uræmia* it is the most efficient remedy at our command. In the forming stage of subacute *rheumatism*, *coryza*, *influenza*, and similar conditions, pilocarpine may be very useful. In *acute* or *chronic Bright's disease* it is of great value, sufficing often in the one case to bring about convalescence, and in the other greatly to prolong life and make it comfortable. The sweats may be repeated daily, bi-weekly, or weekly. Recently, the plan of giving very small doses at short intervals as a diuretic has been strongly commended. The dose of jaborandi is from twenty to sixty grains (1·3–3·9 Gm.), diffused in water, or given in the form of a fluid extract. Jaborandi is usually given in the form either of the fluid extract or of the alkaloid. The full diaphoretic dose of the fluid extract is from forty to sixty minims, of a salt of pilocarpine one-sixth of a grain. When excessive vomiting is produced by the drug, it is better to administer it every ten minutes in fractional doses. After the second or third dose, unless contra-indicated, whiskey and hot water should be given.

It has been proved by elaborate experimentation that in many of their actions upon the human system pilocarpine and atropine are directly antagonistic; and in poisoning by jaborandi or its alkaloid, atropine has the power to arrest the excessive secretion and save life. The value of pilocarpine in atropine poisoning is not quite so certain, but there is enough evidence to demand further trial of it. Dr. Purjesz, of Buda-Pesth, reports (*Centralb. für Prakt. Augenhk.*, 1880) a case in which two and a half grains of atropine sulphate were said to have been taken, and relief, with final recovery, was secured by hypodermic injections of 0·4 grain of pilocarpine every ten minutes until 6·4 grains had been administered. For other similar but less striking cases, see *Brit. Med. Journ.*, Jan. 1887; *Lancet*, July, 1890.

PILULÆ. Pills.

(PĬL'Ů-LÆ.)

Pilules, *Fr.;* Pillen, *G.*

These are globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and which do not require to be given in large doses. Deliquescent substances should not be made into pills; and those which are efflorescent should be previously deprived of their water of crystallization. Care should be taken not to combine materials the mutual reaction of which may result in a change of form.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins; and the addition of a little water to the former, and of a few drops of spirit to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as wheat flour, starch, and powdered gum arabic, or with crumb of bread. Powders must be mixed with soft, solid bodies, as extracts, confections, soap, etc., or with tenacious liquids, as syrup, molasses, honey, mucilage, or glycerin; and the last-mentioned substance has been especially recommended in connection with a little alcohol. Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used; but pills made with it are apt when kept to become hard and of difficult solubility in the liquids of the stomach, and if metallic substances are mixed with it the mass does not work well. A mixture of syrup and powdered gum arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Honey evaporated to about half its bulk has been highly recommended. Confection of rose and glucose are among the best excipients, when the pills are to be kept long. For the same purpose of keeping the pills soft, the addition of a small portion of some fixed oil or deliquescent salt has been recommended; but glycerin is still better. Glycerin incorporated with one-twenty-fifth of its weight of powdered tragacanth is said to cause pills to remain soluble for almost any length of time. The new official mucilage of tragacanth is an excellent excipient. Mr. Martindale prepares a mass by heating together with constant stirring to 115·5° C. (240° F.) five parts by weight of glycerin and one of flour, or, when a very firm mass is required, equal parts of flour and glycerin. (*P. J. Tr.*, 3d ser., i. 412.) It has been objected that pills made with glycerin could not be handsomely gilt or silvered, the lustre of the metal disappearing. This is true, however, only of very recent pills, or of those in which an excess of glycerin has been used. Many powders require only water. Such are all those which contain ingredients capable of forming an adhesive

or viscid solution with that liquid. Care should always be taken that the matter added be not incompatible with the main constituents of the pill.

The materials should be accurately mixed together, and beaten in a mortar till formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric liquors. As pills frequently become very hard by time, it is often convenient to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in waxed paper, putting it in covered pots, and occasionally moistening it as it becomes dry, or, more effectually, by keeping it in glass or well-glazed jars, accurately closed with rubber cloth. The mass is made into pills by rolling it with a spatula, or with a flat, smooth piece of hard wood, into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or, more accurately, by a machine.* The pills receive a spherical form by being rolled between the fingers. M. Mialhe describes a little instrument for rolling pills, composed of two circular plates, one about 12 inches, the other 6, in diameter, the former having a ledge at the border one-third of an inch high, the latter with a similar ledge, varying, according to the size of the pills, from less than a line to nearly two lines, and with a strap on the back by which it can be fitted to the hand. This is to be moved in a rotary manner upon the larger plate, holding the divided portions of the pill mass. (*Journ. de Pharm.*, 3e sér., xvii. 218.) Similar pill-rollers made of wood are now in use. In order to prevent the adhesion of pills to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose magnesium carbonate, rice flour, or starch may be used. Magnesium carbonate is sometimes incompatible with one of the ingredients of the pills; and liquorice root is then preferable, though it occasionally becomes mouldy with very damp pills. The powder of lycopodium, which has been long in use in Europe, is now considerably employed in this country, and is perhaps one of the best substances for the purpose. It is the custom in some sections of the United States, particularly on the Pacific coast, to give the pill a coating of gold or silver leaf. This is done by agitating the pills, prepared without dusting powder, and with their surface still damp, along with gold or silver leaf, in a hollow spherical wooden box made by turning two hemispheres out of hard wood, fitting each other, and provided with a short handle.

It was proposed by M. Garot to cover pills with gelatin, which answers the purpose of concealing their taste and odor and counteracting deliquescence or chemical change from exposure to the air, but it sometimes interferes with their solubility in the stomach. This method of coating is largely used at the present time. One of the best machines that have been devised for gelatin-coating pills is that of H. Maynard, of Chicago. This consists of a circular plate in which are affixed twenty fine needles; the pills are rolled into depressions, and are easily impaled on the points of the needles; they are then dipped into a solution of gelatin, gently rotated, and allowed to cool. Another plan, less effectual, but more convenient, is to introduce the pills into a spherical box, to drop on them enough syrup simply to moisten their surface, then to give a rotary movement to the box until the pills are uniformly covered, and finally to add by degrees either powdered French chalk, elm bark, or some similar substance, shaking the box with each addition, and continuing the process until nothing more will adhere to the pills. The investing material may be rendered agreeable to the taste and smell by aromatic additions, if deemed advisable. M. Calloud found that a good powder for coating pills, because little disposed to attract moisture, is made by boiling one part of flaxseed and three parts of white sugar with sufficient water till a thick mucilage is formed, evaporating this carefully to dryness, and then pulverizing. (*Ibid.*, xxiii. 301.) The same writer has since suggested, as still more effective, a powder made by forming a mucilage with one part of tragacanth and two parts of water, pressing this through linen, mixing it with twenty parts of sugar of milk, spreading the paste thus made in thin layers to dry, and then powdering. The pills may be simply moistened with water and then shaken in the powder. M. Lhermite proposes first to agitate the pills in a mortar with a little concentrated solution of gum, and afterwards to put them into a box containing dry and very finely powdered sugar, to which a rotary motion is given. If the coating be not sufficiently thick, the process may be repeated. (*Ibid.*,

* The common pill-machine is too well known to require description. In *A. J. P.* (xxiv. 315) the reader will find the description of a rotary pill-machine, calculated to prepare large numbers of pills in a short time; and in the same journal (xxvi. 118) that of another, which is considered an improvement on the first. (See, also, *A. J. P.*, Jan. 1869.)

xxv. 460.) The sugar-coating of pills is now conducted upon a great scale by manufacturers, who send large quantities both of popular and of official pills into the market thus protected. The process employed is similar to that of the confectioners in coating almonds. After having been thoroughly dried, the pills are put into a hemispherical tinned copper basin, which is suspended from the ceiling and moved quickly backward and forward with an eccentric motion, so as to cause a constant attrition among the pills. First a little very thick syrup, or syrup of gum, is introduced in order to give a thin coating to their surface; and afterwards very finely powdered and very dry white sugar is sifted or thrown over them, the motion being constantly maintained. The sugar is fixed by the moist surface of the pills, and the coating made compact and smooth by the attrition. The process is aided by a gentle heat, but the heat must be guarded, lest the pills be much softened, and thus lose their shape and even discolor the coating. Dexterous manipulation is necessary in order that the process may succeed thoroughly. For practical remarks on the sugar-coating of pills, see an essay by Mr. H. C. Archibald in *A. J. P.*, 1867, p. 199. On a larger scale a copper pill-coater of peculiar construction, heated by steam pipes, is now used. Still another method, proposed by Mr. E. K. Durden, is to cover the pills with collodion, which completely conceals the taste. The solution employed by Mr. Durden had the sp. gr. 0·810; and two dippings gave a sufficient coating. (*A. J. P.*, xxi. 183.) It is, however, yet to be determined whether a coating of collodion would yield readily to the solvent powers of the gastric juice. M. Blanchard covers pills with a solution of Tolu balsam in ether; but Mr. H. C. Baildon objects to this, that it takes too long to dry, and suggests as a substitute a solution of a drachm of the balsam in three drachms of chloroform, which dries sufficiently in twenty minutes. (*A. J. P.*, xxix. 350.) If old and solid Tolu balsam be selected, it will be less liable to the objection of drying slowly. This balsam is officially employed in coating the U. S. pills of ferrous iodide. A solution of mastic in ether has also been used for coating pills; and the white of egg has been recommended for the same purpose. (*Ibid.*, March, 1862, 137.) Pills are sometimes coated with substances which do not dissolve in the stomach, with the object of permitting the passage of the undissolved pill into the intestines; for this purpose keratin coating has been largely used. (See *Keratin*, PART II.) *Salol* has also been employed, by melting it in an enamelled pan at a temperature of about 50° C. (132° F.) and dropping in the pills, rotating until covered, and then transferring to a dry pan, still rotating (to prevent adhesion) until cold. For further details, see *Drug. Circ.*, 1894, 123; *Pharm. Zeit.*, xxxviii. 527.

Pills which are to be kept long should be well dried, and put into bottles with loosely fitting stoppers to prevent mouldiness. Though the U. S. Pharmacopœia, in almost every instance, orders the mass to be divided into pills, yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass, when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will be found convenient by the apothecary to retain a portion of the mass undivided, especially when it is desirable to keep the pills soft. The British Pharmacopœia furnishes formulas for pill masses, using the title of "Pilula" instead of "Massa," the title of the class adopted by the U. S. Pharmacopœia; there is, in our opinion, a decided advantage in selecting a name for the class which is not likely to be confused with that used for the divided pills.

Compressed pills are made directly from the medicinal substance without the aid of an excipient. The drug, if not already in powder, is reduced to such, and then forced into pill shape by means of a powerful press. For certain substances which naturally exist in powder, such as quinine bisulphate, potassium bromide, and potassium iodide, and which have some cohesiveness and yet are of easy solubility, the process is a good one. An apparatus has been contrived by J. P. Remington for compressing pills (see 16th ed. U. S. D., and *Practice of Pharmacy*, page 1116). It is made of cast steel; the base has two countersunk depressions with a short post in the centre of each, and a lenticular depression is made in the upper surface of each post. A steel cylinder having a central aperture of the diameter of the post is placed in the depression, the proper quantity of powder is introduced, and the plunger, which has a corresponding lenticular depression on its lower surface, is placed on the powder and is struck a quick blow with a mallet; the powder is compressed, and the pill adheres to the cylinder; by removing the cylinder and holding it over a box and tapping the plunger again lightly, the pill is forced out and falls into a box.

Compressed pills are now used to an enormous extent, being made by various manufacturers with machinery of ingenious construction: the fact of their requiring no excipient, the ease

with which they can be tested, and their permanent character (in most cases being just as valuable years after they were made as when fresh) have caused their extensive employment. Care should be taken, however, not to use them in those few cases where very prompt action is required, as the powerful compression to which they are subjected renders them less quickly effective than the same drug administered in the form of a loose powder.

PILULÆ ALOES. U. S. (Br.) Pills of Aloes.

(PĬL'Ů-LÆ ĂL'Ǫ-ĒŞ.)

Pilula Aloes Barbadensis, *Br.;* Pill of Barbados Aloes, Pill of Socotrine Aloes; Pilules d'Aloès, *Fr.;* Aloepillen, *G.*

"Purified Aloes, in fine powder, *thirteen grammes* [or 200 grains]; Soap, in fine powder, *thirteen grammes* [or 200 grains]; Water, *a sufficient quantity*, To make *one hundred pills*. Beat the powders together with Water, so as to form a mass, and divide it into *one hundred pills*." *U. S.*

"Barbados Aloes, in powder, 2 *ounces* (Imperial) or 40 grammes; Hard Soap, in powder, 1 *ounce* (Imp.) or 20 grammes; Oil of Caraway, 1 *fl. drachm* (Imp. meas.) or 2·5 cubic centimetres; Confection of Roses, 1 *ounce* (Imp.) or 20 grammes or a sufficient quantity. Mix to form a mass." *Br.*

The former British process for *Pill of Socotrine Aloes* was the same, except that Socotrine was substituted for Barbadoes Aloes, and the volatile Oil of Nutmeg for Oil of Caraway.

The soap, in this formula, not only serves to impart a proper consistence to the aloes, but is thought to qualify its operation and diminish its liability to irritate the rectum. Five of the U. S. pills, containing ten grains (0·65 Gm.) of aloes, may be given with a view to their purgative effect; but the preparation is usually employed as a laxative in *habitual costiveness*, in the dose of one, two, or three pills at bedtime. The British pill is of very nearly the same strength.

PILULÆ ALOES ET ASAFŒTIDÆ. U. S. (Br.) Pills of Aloes and Asafetida.

(PĬL'Ů-LÆ ĂL'Ǫ-ĒŞ ĔT ĂS-Ą-FŒT'Į-DÆ—ăs-ą-fĕt'ĭ-dē.)

Pilula Aloes et Asafetidæ, *Br.;* Pilules d'Aloès et Asefétide, *Fr.;* Aloe- und Asafœtida-Pillen, *G.*

"Purified Aloes, in fine powder, *nine grammes* [or 139 grains]; Asafetida, *nine grammes* [or 139 grains]; Soap, in fine powder, *nine grammes* [or 139 grains]; Water, *a sufficient quantity*, To make *one hundred pills*. Beat the solids together with Water, so as to form a mass, and divide it into *one hundred pills*." *U. S.*

"Socotrine Aloes, in powder, 1 *ounce* (Imperial) or 20 grammes; Asafetida, in powder, 1 *ounce* (Imp.) or 20 grammes; Hard Soap, in powder, 1 *ounce* (Imp.) or 20 grammes; Confection of Roses, 1 *ounce* (Imp.) or 20 grammes or a sufficient quantity. Mix to form a mass." *Br.*

These pills are peculiarly adapted, by the stimulant and carminative properties of the asafetida, to cases of *costiveness* attended with flatulence and debility of the digestive organs. Each pill contains about four grains (0·26 Gm.) of the mass. Dose, from two to five pills.

PILULÆ ALOES ET FERRI. U. S. (Br.) Pills of Aloes and Iron.

(PĬL'Ů-LÆ ĂL'Ǫ-ĒŞ ĔT FĔR'RĪ.)

Pilula Aloes et Ferri, *Br.;* Pilulæ Aloeticæ Ferratæ, s. Pilulæ Italicæ Nigræ, *P. G.;* Pilules d'Aloès et de Fer, *Fr.;* Aloe- und Eisenpillen, Italienische Pillen, *G.*

"Purified Aloes, in fine powder, *seven grammes* [or 108 grains]; Dried Ferrous Sulphate, *seven grammes* [or 108 grains]; Aromatic Powder, *seven grammes* [or 108 grains]; Confection of Rose, *a sufficient quantity*, To make *one hundred pills*. Beat the powders together with Confection of Rose, so as to form a mass, and divide it into *one hundred pills*." *U. S.*

"Exsiccated Ferrous Sulphate, 1 *ounce* (Imperial) or 20 grammes; Barbados Aloes, in powder, 2 *ounces* (Imp.) or 40 grammes; Compound Powder of Cinnamon, 3 *ounces* (Imp.) or 60 grammes; Syrup of Glucose, 3 *ounces* (Imp.) or 60 grammes or a sufficient quantity. Mix to form a mass." *Br.*

This pill differs from the preparation of the same name in the British Pharmacopœia in the substitution of aromatic powder for the compound powder of cinnamon. It is essentially an old preparation of the Edinburgh Pharmacopœia, which, having been omitted in the original British, has been resumed in the present edition. The Br. Ph. 1898 improved this mass by substituting exsiccated ferrous sulphate for the crystallized salt formerly employed, and by

the use of syrup of glucose instead of confection of rose. It is said that the laxative power of aloes is increased, and its tendency to irritate the rectum diminished, by combination with ferrous sulphate. This pill is especially adapted to *amenorrhœa* with debility of the stomach and constipation. The dose is from one to three pills.

PILULÆ ALOES ET MASTICHES. U. S. Pills of Aloes and Mastic.

(PĬL'Ů-LÆ ĂL'Ǫ-ĒŞ ĔT MĂS'TĮ-ĢHĒŞ.)

Lady Webster's Dinner Pills, *E.;* Pilules d'Aloès et de Mastic, *Fr.;* Aloe- und Mastix-Pillen, *G.*

"Purified Aloes, in fine powder, *thirteen grammes* [or 200 grains]; Mastic, in fine powder, *four grammes* [or 62 grains]; Red Rose, in fine powder, *three grammes* [or 46 grains]; Water, *a sufficient quantity*, To make *one hundred pills*. Beat the powders together with Water, so as to form a mass, and divide it into *one hundred pills*." *U. S.*

In this U. S. P. 1890 pill the proportion of mastic has been slightly increased and that of red rose somewhat diminished. Each of these pills contains about three grains of the solid ingredients and nearly two grains (0·13 Gm.) of aloes. They are in imitation of Lady Webster's dinner pills, and one of them may be given as a laxative at bedtime, or before a meal. The mastic has probably little other effect than to impair the solubility of the aloes, and thus give it a still greater tendency to act on the lower bowels.*

PILULÆ ALOES ET MYRRHÆ. U. S. (Br.) Pills of Aloes and Myrrh.

(PĬL'Ů-LÆ ĂL'Ǫ-ĒŞ ĔT MŸR'RHÆ.)

Pilula Aloes et Myrrhæ, *Br.;* Rufus's Pills, *E.;* Pilules d'Aloès et de Myrrhe, Pilules de Rufus, *Fr.;* Rufus'sche Pillen, *G.*

"Purified Aloes, in fine powder, *thirteen grammes* [or 200 grains]; Myrrh, in fine powder, *six grammes* [or 93 grains]; Aromatic Powder, *four grammes* [or 62 grains]; Syrup, *a sufficient quantity*, To make *one hundred pills*. Beat the powders together with Syrup, so as to form a mass, and divide it into *one hundred pills*." *U. S.*

"Socotrine Aloes, in powder, 2 *ounces* (Imperial) or 40 grammes; Myrrh, in powder, 1 *ounce* (Imp.) or 20 grammes; Syrup of Glucose, 1½ *ounces* (Imp.) or 30 grammes or a sufficient quantity. Mix to form a mass." *Br.*

In this U. S. P. 1890 pill the proportion of myrrh has been slightly decreased and that of aromatic powder somewhat increased. The Br. Ph. 1898 dropped saffron, treacle, and glycerin from the formula used in former Pharmacopœias, and substituted for them syrup of glucose.

This composition has been long in use, under the name of *Rufus's Pills*. It is employed, as a warm stimulant cathartic, in *general debility* attended with *constipation*, and in *retention or suppression of the menses*. From three to six pills, or from ten to twenty grains (0·65–1·3 Gm.) of the mass may be given for a dose.

PILULA ALOES SOCOTRINÆ. Br. Pill of Socotrine Aloes.

(PĬL'Ů-LĄ ĂL'Ǫ-ĒŞ SŎC-Ǫ-TRĪ'NÆ.)

"Socotrine Aloes, in powder, 2 *ounces* (Imperial) or 40 grammes; Hard Soap, in powder, 1 *ounce* (Imp.) or 20 grammes; Oil of Nutmeg, 1 *fl. drachm* (Imp. meas.) or 2·5 cubic centimetres; Confection of Roses, 1 *ounce* (Imp.) or 20 grammes or a sufficient quantity. Mix to form a mass." *Br.*

For properties and dose, see *Pilulæ Aloes*, p. 1041.

* The following is the formula for the aloetic pills usually called *dinner pills* or *Lady Webster's pills*. They are the *Pilulæ Stomachicæ* of the fifth edition of the Paris Codex, 1758. Take of the best aloes six drachms; mastic and red roses, each, two drachms; syrup of wormwood sufficient to form a mass, to be divided into pills of three grains each. Common syrup may be substituted for syrup of wormwood. One or two of these pills, taken shortly before a meal, will usually produce one free evacuation.

The Philadelphia College of Pharmacy has adopted the following formulas for the compound aloetic preparations commonly called *Hooper's* and *Anderson's pills:*

"*Hooper's Female Pills.* ℞ Aloës Barbadensis ℥viij, Ferri Sulphatis Exsiccati ℥ij, ℥iss, *vel* Ferri Sulphatis Crystal. ℥iv, Extracti Hellebori ℥ij, Myrrhæ ℥ij, Saponis ℥ij, Canellæ in pulv. trit. ℥j, Zingiberis in pulv. trit. ℥j.—Beat them well together into a mass with water, and divide into pills, each containing two and a half grains." (*Journ. of the Phila. Coll. of Pharm.*, v. 25.)

"*Anderson's Scots Pills.* ℞ Aloës Barbadensis ℥xxiv, Saponis ℥iv, Colocynthidis ℥j, Cambogiæ ℥j, Olei Anisi f℥ss. Let the aloes, colocynth, and gamboge be reduced to a very fine powder; then beat them and the soap with water into a mass, of a proper consistence to divide into pills, each containing three grains."

PILULÆ ANTIMONII COMPOSITÆ. U. S. (Br.) Compound Pills of Antimony. [Plummer's Pills.]

(PĬL'Ū-LÆ ĂN-TĪ-MŌ'NĪ-Ī CŌM-PŎŞ'Ī-TÆ.)

Pilula Hydrargyri Subchloridi Composita, *Br.;* Pilula Calomelanos Composita, *Br.* 1864; Compound Pill of Mercurous Chloride, Compound Calomel Pill; Pilules altérantes composées, Pilules antidartreuses, Pilules de Plummer, *Fr.;* Plummer'sche Pillen, *G.*

"Sulphurated Antimony, *four grammes* [or 62 grains]; Mild Mercurous Chloride, *four grammes* [or 62 grains]; Guaiac, in fine powder, *eight grammes* [or 123 grains]; Castor Oil, *a sufficient quantity*, To make *one hundred pills.* Beat the powders together with the Castor Oil, added a few drops at a time, so as to form a mass, and divide it into *one hundred pills.*" *U. S.*

"Mercurous Chloride, 1 *ounce* (Imperial) or 25 grammes; Sulphurated Antimony, 1 *ounce* (Imp.) or 25 grammes; Guaiacum Resin, in powder, 2 *ounces* (Imp.) or 50 grammes; Castor Oil, 180 *grains* or 10·3 grammes; Alcohol (90 per cent.), 1 *fl. drachm* (Imp. meas.) or 3 cubic centimetres or a sufficient quantity. Mix to form a mass." *Br.*

The formula for this pill in the U. S. P. 1890 has been altered by adopting the British method of using castor oil as an excipient instead of mucilage of tragacanth: this change is of doubtful utility, the pills when kept acquiring an unpleasant odor. The oil is, however, a partial solvent for the guaiac.

We prefer the title "Compound Calomel Pill" of the former British Pharmacopœia, as not liable to any mistake, and as most expressive of the quality of the medicine. The antimonial employed, though under a different name, is identical with the old U. S. precipitated sulphide. According to Vogel, a reaction takes place between the calomel and the sulphurated antimony, resulting in the production of antimony chloride and mercury sulphide. The preparation was originally introduced to the notice of the profession by Dr. Plummer, who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's Pills.* The combination is well adapted to the treatment of *chronic rheumatism*, and of scaly and other *eruptive diseases of the skin*, especially when accompanied with a syphilitic taint. One to two pills or more may be given morning and evening.

PILULÆ ASAFŒTIDÆ. U. S. Pills of Asafetida.

(PĬL'Ū-LÆ ĂS-Ą-FŒT'Ī-DÆ.)

Pilules d'Asefétide, *Fr.;* Asafœtida-Pillen, *G.*

"Asafetida, *twenty grammes* [or 325 grains]; Soap, in fine powder, *six grammes* [or 93 grains]; Water, *a sufficient quantity*, To make *one hundred pills.* Beat the solids together with Water, so as to form a mass, and divide it into *one hundred pills.*" *U. S.*

Each of these pills contains three grains (0·20 Gm.) of the gum-resin. They are a convenient form for administering asafetida, the unpleasant odor and taste of which render it very offensive in the liquid state.

PILULA CAMBOGIÆ COMPOSITA. Br. Compound Pill of Gamboge.

(PĬL'Ū-LĄ CĄM-BŌ'ĢĪ-Æ CŌM-PŎŞ'Ī-TĄ.)

"Gamboge, in powder, 1 *ounce* (Imperial) or 25 grammes; Barbados Aloes, in powder, 1 *ounce* (Imp.) or 25 grammes; Compound Powder of Cinnamon, 1 *ounce* (Imp.) or 25 grammes; Hard Soap, in powder, 2 *ounces* (Imp.) or 50 grammes; Syrup of Glucose, 1 *ounce* (Imp.) or 25 grammes or a sufficient quantity. Mix to form a mass." *Br.*

This is an active purgative pill, and may be given in the dose of from five to fifteen grains (0·33–1 Gm.). The formula is that of Dr. George Fordyce, simplified.

PILULÆ CATHARTICÆ COMPOSITÆ. U. S. Compound Cathartic Pills.

(PĬL'Ū-LÆ CĄ-THÄR'TĪ-ÇÆ CŌM-PŎŞ'Ī-TÆ.)

Antibilious Pills, *E.;* Pilules cathartiques composées, *Fr.;* Abführpillen, *G.*

"Compound Extract of Colocynth, *eighty grammes* [or 2 ounces av., 360 grains]; Mild Mercurous Chloride, *sixty grammes* [or 2 ounces av., 51 grains]; Extract of Jalap, *thirty grammes* [or 1 ounce, 26 grains]; Gamboge, in fine powder, *fifteen grammes* [or 232 grains]; Water, *a sufficient quantity*, To make *one thousand pills.* Mix the powders intimately; then gradually incorporate them with the Extract of Jalap and a sufficient quantity of Water to form a mass, to be divided into *one thousand pills.*" *U. S.*

This cathartic compound was first made official in the second edition of the U. S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action and a peculiar tendency to the biliary organs. Such an official preparation was much wanted in this country, in which bilious fevers, and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk is accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel; and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact, abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. Nor is it difficult, in this case, to reconcile the result of observation with physiological principles. Cathartic medicines act on different parts of the alimentary canal and organs secreting into it. In small doses, both the irritation which they occasion and their purgative effect are proportionally lessened. If several are administered at the same time, each in a diminished dose, it is obvious that the combined purgative effect of all will be experienced, while the irritation, being feeble in each part affected, and diffused over a large space, will be less sensible to the patient, and will more readily subside. In the compound cathartic pills, most of the active purgatives in common use are associated together in proportions corresponding with their respective doses, so that an excess of any one ingredient is guarded against, and violent irritation from this cause prevented. The present official process does not differ from that of the U. S. P. 1880, except in the substitution of the extract of jalap for the abstract, the latter being no longer official. This, however, does not alter the composition, and it makes a smaller pill. It is highly important for the efficiency of these pills that they be prepared in exact compliance with the directions, and that the *compound extract of colocynth* and the *extract of jalap* used be of good quality. When they fail, the result is generally ascribable to the substitution of jalap for the extract, or to the use of a compound extract of colocynth made with nearly inert scammony, inferior aloes, and insufficient colocynth, and altogether badly prepared. (See a paper by G. H. Chas. Klie, *A. J. P.*, April, 1878.)

Three of the pills are a medium dose for an adult. Each pill weighs about 3 grains (0·194 Gm.), and contains 2·85 grains (0·185 Gm.) of active ingredients. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required, but is particularly applicable to the early stages of *bilious fevers*, to *hepatitis*, *jaundice*, and all those derangements which depend on congestion of the portal circle.

PILULÆ CATHARTICÆ VEGETABILES. U. S. Vegetable Cathartic Pills.

(PĬL′Ŭ-LÆ CA-THĂR′TĬ-ÇÆ VĔG-Ē-TĂB′Ĭ-LĒS.)

"Compound Extract of Colocynth, *sixty grammes* [or 2 ounces av., 51 grains]; Extract of Hyoscyamus, *thirty grammes* [or 1 ounce av., 25 grains]; Extract of Jalap, *thirty grammes* [or 1 ounce av., 25 grains]; Extract of Leptandra, *fifteen grammes* [or 231 grains]; Resin of Podophyllum, *fifteen grammes* [or 231 grains]; Oil of Peppermint, *eight cubic centimeters* [or 130 minims]; Water, *a sufficient quantity*, To make *one thousand pills*. Mix the Compound Extract of Colocynth intimately with the Resin of Podophyllum and incorporate the Oil of Peppermint. Rub the Extracts of Hyoscyamus, Jalap, and Leptandra with enough Water to render them plastic, then beat them together with the mixture first prepared, using a sufficient quantity of Water to form a mass, to be divided into *one thousand pills*." *U. S.*

This pill has been introduced into the U. S. P. 1890 with the view of furnishing a formula for a cathartic pill without a mercurial. The oil of peppermint and extract of hyoscyamus are added to the cathartics to prevent griping. The dose is three pills, and they may be given in the place of compound cathartic pills. It is not likely, however, that the latter will be supplanted by the new addition.

PILULA COLOCYNTHIDIS COMPOSITA. Br. Compound Pill of Colocynth.

(PĬL′Ŭ-LĄ CŎL-Ǫ-CŸN′THĮ-DĬS CǪM-PŎṢ′Ĭ-TĄ.)

Pilules de Coloquinte composées, Pilules cochées mineures, *Fr.*; Coloquinten-Pillen, *G.*

"Colocynth Pulp, in powder, 1 *ounce* (Imperial) or 20 grammes; Barbados Aloes, in powder, 2 *ounces* (Imp.) or 40 grammes; Scammony Resin, in powder, 2 *ounces* (Imp.) or 40

grammes; Potassium Sulphate, in very fine powder, ¼ *ounce* (Imp.) or 5 grammes; Oil of Cloves, 2 *fl. drachms* (Imp. meas.) or 5 cubic centimetres; Distilled Water, *a sufficient quantity*. Triturate the Oil of Cloves with the Potassium Sulphate; add the Colocynth Pulp; mix; add the Barbados Aloes and Scammony Resin; after mixing intimately add the Distilled Water and beat to form a mass." *Br.*

This is not, like the old London pills of the same name, merely another form of the compound extract of colocynth, though containing essentially the same materials,—one great difference being that colocynth and aloes are used in substance in the pill, instead of in the state of extract. Potassium sulphate is used to promote the more complete division of the aloes and scammony. The preparation is actively cathartic in the dose of from five to twenty grains (0·33–1·3 Gm.). (See *Pilulæ Colocynthidis Compositæ*, N. F.)

PILULA COLOCYNTHIDIS ET HYOSCYAMI. Br. Pill of Colocynth and Hyoscyamus.

(PĬL'Ū-LĄ CŎL-Ǫ-CĬN'THI-DĪS ĔT HĬ-ǪS-CĪ'Ą-MĪ.)

"Compound Pill of Colocynth, 2 *ounces* (Imperial) or 50 grammes; Extract of Hyoscyamus, 1 *ounce* (Imp.) or 25 grammes. Mix to form a mass." *Br.*

This is an old official of the Edinburgh College. It is asserted that the compound pill and compound extract of colocynth are almost entirely deprived of their griping tendency by combination, as above, with extract of hyoscyamus, without losing any of their purgative power. The dose is from five to twenty grains (0·33–1·3 Gm.).

PILULÆ FERRI CARBONATIS. U. S. (Br.) Pills of Ferrous Carbonate.

[Ferruginous Pills. Chalybeate Pills. Blaud's Pills.]

(PĬL'Ū-LÆ FĔR'RĪ CĂR-BǪ-NĀ'TĪS.)

Pilula Ferri, *Br.;* Iron Pill; Pilules de Griffith, Pilules de Fer et de Myrrhe composées, *Fr.;* Griffith'sche Pillen, *G.*

"Ferrous Sulphate, in clear crystals, *sixteen grammes* [or 246 grains]; Potassium Carbonate, *eight grammes* [or 123 grains]; Sugar, *four grammes* [or 62 grains]; Tragacanth, in fine powder, *one gramme* [or 15·5 grains]; Althæa, in No. 60 powder, *one gramme* [or 15·5 grains]; Glycerin, Water, each, *a sufficient quantity*, To make *one hundred pills.* Rub the Potassium Carbonate, in a mortar, with a sufficient quantity (about *ten drops* each) of Glycerin and Water, then add the Ferrous Sulphate and Sugar, previously triturated together to a uniform powder, and beat the mass thoroughly, until it assumes a greenish color. When the reaction appears to have terminated, incorporate the Tragacanth and Althæa, and, if necessary, add a little more Water, so as to obtain a mass of a pilular consistence. Divide this into *one hundred pills.* These pills should be freshly prepared, when wanted." *U. S.*

"Exsiccated Ferrous Sulphate, in fine powder, 150 *grains* or 15 grammes; Exsiccated Sodium Carbonate, in fine powder, 95 *grains* or 9·5 grammes; Gum Acacia, in powder, 50 *grains* or 5 grammes; Tragacanth, in powder, 15 *grains* or 1·5 grammes; Syrup, 150 *grains* or 15 grammes; Glycerin, 10 *grains* or 1 gramme; Distilled Water, 20 *grains* or 2 grammes or a sufficient quantity. To the Syrup, Glycerin, and Distilled Water, previously mixed, add the Ferrous Sulphate; mix; add quickly the Sodium Carbonate; mix; set aside for fifteen minutes, or until the reaction is complete; add the Gum Acacia and Tragacanth, and incorporate thoroughly. If divided into five-grain pills, each pill will contain about 1 grain of ferrous carbonate." *Br.*

In the Br. Ph. 1898 exsiccated ferrous sulphate and sodium carbonate replace the crystallyzed salts of the former authority.

In the U. S. P. 1890 the name of this pill was changed to *Pilulæ Ferri Carbonatis* and the *Pilulæ Ferri Compositæ* of the U. S. P. 1880 was dropped,* which leads to a complication; the present title will surely produce confusion, for many prescriptions are written for "Pil. Ferri Carb.," and this has always hitherto meant pills of Vallet's mass, whereas it will now mean "Blaud's Pills." A better title to adopt, if a change was demanded, would have been simply *Pilulæ Ferri.*

* *Pilulæ Ferri Compositæ. Compound Pills of Iron.* "Myrrh, in fine powder, *one hundred and fifty grains* (9·75 Gm.); Carbonate of Sodium, *seventy-five grains* (4·85 Gm.); Sulphate of Iron, *seventy-five grains* (4·85 Gm.); Syrup, *a sufficient quantity*, To make *one hundred pills.* Rub the Myrrh, first with the Carbonate of Sodium and afterward with the Sulphate of Iron, until they are thoroughly mixed; then beat them with Syrup so as to form a mass, and divide it into *one hundred pills.*" *U. S.* 1880.

This preparation is closely analogous to the *Mistura Ferri Composita* in properties and composition. It is a good emmenagogue and chalybeate tonic. As its peculiar advantages depend upon the presence of ferrous carbonate, which speedily changes into the ferric salt on exposure, it is proper that only so much of the mass should be prepared as may be wanted for immediate use. From two to six pills may be given at a dose three times a day. They are sometimes called *Griffith's pills.* They closely resemble *Blaud's ferruginous pills*, made originally in 1831, and celebrated in France as a remedy in *chlorosis*, prepared from equal weights of ferrous sulphate and potassium carbonate, made into a pilular mass. (See *P. J. Tr.*, 1894, 131.) The pills contain, as the result of double decomposition, ferrous carbonate and potassium sulphate. MM. Van de Velde and Van Melckebeke prefer the sodium bicarbonate to the potassium salt.

PILULÆ FERRI IODIDI. U. S. Pills of Ferrous Iodide.

(PĬL'Ŭ-LÆ FĔR'RĪ Ī-ŎD'Ĭ-DĪ.)

Pilules d'Iodure de Fer, Pilules de Blancard, *Fr.;* Eisenjodür-Pillen, *G.*

"Reduced Iron, *four grammes* [or 62 grains]; Iodine, *five grammes* [or 77 grains]; Glycyrrhiza, in No. 60 powder, *four grammes* [or 62 grains]; Sugar, in fine powder, *four grammes* [or 62 grains]; Extract of Glycyrrhiza, in fine powder, *one gramme* [or 15·5 grains]; Acacia, in fine powder, *one gramme* [or 15·5 grains]; Water, Balsam of Tolu, Ether, each, *a sufficient quantity*, To make *one hundred pills.* To the Reduced Iron, contained in a small mortar, add *six cubic centimeters* [or 97 minims] of Water, and then, gradually, the Iodine, constantly triturating, until the mixture ceases to have a reddish tint. Then add the remaining powders, previously well mixed together, and mix the whole thoroughly. Transfer the mass to a porcelain capsule, and evaporate the excess of moisture, on a water-bath, with constant stirring, until the mass has acquired a pilular consistence. Then divide it into *one hundred pills.* Dissolve *ten grammes* [or 154 grains] of Balsam of Tolu in *fifteen cubic centimeters* [or 243 minims] of Ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle. Pills of Ferrous Iodide should be devoid of the smell of iodine. If a few of the pills be triturated with water, the filtrate should not assume more than a light blue tint on the addition of starch test-solution (absence of more than traces of *free iodine*)." *U. S.*

This process does not differ essentially from that formerly official.*

The pills of ferrous iodide were introduced into the U. S. Pharmacopœia at the revision of 1850. The present official pills are formed on the plan proposed by Prof. Procter, in imitation of *Blancard's pills* (*A. J. P.*, May, 1860), and are much superior to those made by the U. S. process of 1850, or by that of the British Pharm. 1885. M. Magnes-Lahens especially recommends the following formula. "Take of pure Iodine 4·10 grammes; Powdered Iron 1·90 grammes; Powdered Sugar 2·50 grammes; Powdered Gum Arabic 2·50 grammes; Distilled Water 2·50 grammes. Put in an iron dish the Water and the powdered Iron, add the Iodine gradually, and facilitate the reaction by stirring with a spatula of iron and by warming a little; when the reaction is complete, add the Gum and the Sugar, then heat to about 50° C. (122° F.), stirring until the mass ceases to drop when a little is taken up on the spatula. If necessary, five grammes of powdered liquorice root may be incorporated into the mass, which is then to be rolled into one hundred pills." (*A. J. P.*, 1873, p. 498.) The iodine and iron unite directly to form ferrous iodide in solution, which is protected against the oxidizing influence

* *Pills of Ferrous Iodide.—Wm. R. Warner, Jr.'s, Process.* Take of iodine 4634 grains; iron wire 1600 grains; sugar 4500 grains; marshmallow powder 4500 grains; gum 2200 grains; iron by hydrogen 566 grains; distilled water 3000 grains. Place the iron wire in a Florence flask, quart capacity, add the water, place on a sand-bath, and gently heat; then add the iodine in such divided portions as the reaction will admit of, without raising the temperature so high as to drive off violet fumes of iodine. Finally, add all the iodine, and continue the heat until the reaction has ceased, and the liquid shows no blue color with starch mucilage. The weight of the flask must be previously determined, and at this point the weight of the contents should be 9234 grains; if not, sufficient water must be added to make it so. Now mix thoroughly together the gum, sugar, marshmallow, and iron by hydrogen, and strain upon them the contents of the flask; mix quickly, and knead thoroughly, until a pill mass is formed, then divide it into three-grain pills, each containing one grain of ferrous iodide (iodine, iron, and water of crystallization). The pills, after being hardened in a warm, dry atmosphere, covered with starch powder, may be coated with a solution of gum mastic in ether or tolu in alcohol, in the proportion of four drachms to the fluidounce. An *extemporaneous sugar-coating* may be effected to a reasonable degree of perfection in the following manner. Mix together thoroughly equal quantities of sugar, gum, and starch. Moisten the surface of the pills with an equal mixture of simple syrup and water, and then place them on the powder in a shallow dish, and give the same a centrifugal motion, so that they may be equally coated by the moisture of the syrup, which will agglutinate the particles of the powder. (*Drug. Circ.*, 1884, p. 4.)

of the air by the sugar and excess of reduced iron, while the liquorice and gum serve to give due consistence and plasticity to the pilular mass. The pills are still further protected from the air by the impervious coating of balsam of Tolu, which readily yields to the softening and solvent properties of the gastric liquids. The great disadvantage of the pill of ferrous iodide, as ordinarily prepared, is that it will not keep,—crumbling by time and exposure, and evolving iodine in consequence of the oxidation of the iron. The preparation, made according to the U. S. formula of 1870, stood the test of time; and we have seen pills which, four years after their preparation, exhibited no signs of change. Each pill contains about a grain (0·065 Gm.) of ferrous iodide and one-fifth of a grain (0·012 Gm.) of reduced iron. The therapeutic uses of this preparation are the same as those of ferrous iodide. (See *Ferri Iodidum.*)

PILULA GALBANI COMPOSITA. Br. Compound Pill of Galbanum.

[Compound Pill of Asafetida.]

(PĬL'Ů-LĄ GĂL'BĄ-NĪ CǪM-PŎŞ'Į-TĄ.)

"Asafetida, 2 *ounces* (Imperial) or 50 grammes; Galbanum, 2 *ounces* (Imp.) or 50 grammes; Myrrh, 2 *ounces* (Imp.) or 50 grammes; Syrup of Glucose, 1 *ounce* (Imp.) or 25 grammes or a sufficient quantity. Heat all together on a water-bath, stirring until the mass is uniform in consistence." *Br.* This mass was formerly termed in the British Pharmacopœia *Pilula Asafœtidæ Composita.* The treacle used as an excipient has been replaced by syrup of glucose. It is given as an antispasmodic and emmenagogue in *chlorosis* and *hysteria.* The dose is from two to four pills or from five to twenty grains (0·33–1·3 Gm.).*

PILULA IPECACUANHÆ CUM SCILLA. Br. Pill of Ipecacuanha with Squill.

(PĬL'Ů-LĄ ĬP-Ę-CĂC-Ů-ĂN'HÆ CŬM SÇĬL'LĄ.)

"Compound Powder of Ipecacuanha, 3 *ounces* (Imperial) or 30 grammes; Squill, in powder, 1 *ounce* (Imp.) or 10 grammes; Ammoniacum, in powder, 1 *ounce* (Imp.) or 10 grammes; Syrup of Glucose, *a sufficient quantity.* Mix to form a mass. This Pill contains about 5 per cent. of Opium." *Br.*

This is a good combination of expectorants, well adapted to *chronic bronchitis* with either deficient or greatly excessive expectoration, and to the advanced stages of the acute disease offering similar indications. The dose is from five to ten grains (0·33–0·65 Gm.).

PILULÆ OPII. U. S. Pills of Opium.

(PĬL'Ů-LÆ Ō'PĮ-Ī.)

Pilules d'Opium, *Fr.;* **Opiumpillen,** *G.*

"Powdered Opium, *six and one-half grammes* [or 100 grains]; Soap, in fine powder, *two grammes* [or 31 grains]; Water, *a sufficient quantity*, To make *one hundred pills.* Beat the powders together with Water, so as to form a mass, and divide it into *one hundred pills.*" *U. S.*

This process is designed merely to furnish a convenient formula for putting opium into pilular form, preferable to the mode sometimes practised of making the pills directly from the unpowdered mass of opium as found in commerce. The soap answers no other purpose than to give a due consistence, and is therefore in small proportion. Opium pills are official in the British Pharmacopœia under the name of *Pilula Saponis Composita* (see page 1049). The object of giving them this title is probably to prevent the patient from learning from the prescription that the pills contain opium. As hard old opium pills are sometimes preferred, in cases of irritable stomach, in consequence of their slow solution, it is proper for the pharmacist to keep some in this state to meet the prescription of the physician. Of the pills above directed, each contains one grain (0·065 Gm.) of powdered opium, and one is a full dose.

PILULÆ PHOSPHORI. U. S. (Br.) Pills of Phosphorus.

(PĬL'Ů-LÆ PHŎS'PHǪ-RĪ.)

Pilula Phosphori, *Br.;* **Phosphorus Pill.**

"Phosphorus, *six centigrammes* [or 0·93 grains]; Althæa, in No. 60 powder, *six grammes* [or 93 grains]; Acacia, in fine powder, *six grammes* [or 93 grains]; Chloroform, Glycerin,

* The U. S. P. 1880 gave the following formula for this preparation: "Galbanum, *one hundred and fifty grains* (9·75 Gm.); Myrrh, *one hundred and fifty grains* (9·75 Gm.); Asafetida, *fifty grains* (3·25 Gm.); Syrup, *a sufficient quantity,* To make *one hundred pills.* Beat them together so as to form a mass, and divide it into *one hundred pills.*"

Water, Balsam of Tolu, Ether, each, *a sufficient quantity*, To make *one hundred pills*. Dissolve the Phosphorus, in a test-tube, in *five cubic centimeters* [or 81 minims] of Chloroform, with the aid of a very gentle heat, replacing from time to time any of the Chloroform which may be lost by evaporation. Mix the Althæa and Acacia in a mortar, next add the solution of Phosphorus, then immediately afterwards a sufficient quantity (about *four cubic centimeters*) [or 65 minims] of a mixture of *two volumes* of Glycerin and *one volume* of Water, and quickly form a mass, to be divided into *one hundred pills*. Dissolve *ten grammes* [or 154 grains] of Balsam of Tolu in *fifteen cubic centimeters* [or 243 minims] of Ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle." *U. S.*

" Phosphorus, 10 *grains* or 1 gramme; White Beeswax, melted, 125 *grains* or 12·5 grammes; Lard, melted, 125 *grains* or 12·5 grammes; Kaolin, 115 *grains* or 11·5 grammes; Carbon Bisulphide, 33 *minims* or 3 cubic centimetres or a sufficient quantity. Place the melted Wax and Lard in a slightly warmed mortar, and stir until the mixture has the consistence of cream. Dissolve the Phosphorus in the Carbon Bisulphide and carefully mix the solution with the melted fats; add the Kaolin; mix well together. Keep the mixture immersed in cold water in a bottle from which the light is excluded. When dispensed, every *three grains* of the mixture is to be incorporated with *one grain* of Gum Acacia in powder; and the resulting pills should be varnished. Phosphorus Pill, including the Gum Acacia, contains 2 per cent. of Phosphorus; hence, is nearly double the strength of the Phosphorus Pill of the British Pharmacopœia of 1885." *Br.*

The increasing use of phosphorus in the free state made the introduction of phosphorus pills a necessity. The problem of preventing the oxidation of the phosphorus is believed to be solved by dissolving it in an excess of warm chloroform: this is accomplished in a stoppered test-tube, for it has been shown that no oxidation takes place in the presence of chloroform vapor. It is necessary to form the mass quickly, so that the chloroform may not all evaporate and leave the phosphorus exposed to the action of the air. Chloroform is preferred to carbon disulphide, for, although the latter is a better solvent, it is difficult to rid the mass of the disgusting odor. (See *A. J. P.*, 1875, 253, 254, 335, 501; 1876, 56; 1877, 135; 1878, 584; and *N. R.*, 1876, 189, 332; 1877, 32; *Drug. Circ.*, 1883, 180; *P. J. Tr.*, 1883, 923.) Of the British mass, four grains of the mass, including the acacia, will contain $\frac{1}{12}$ of a grain of phosphorus (0·0054 Gm.), and the dose is therefore one-half grain (0·03 Gm.), equivalent to $\frac{1}{96}$ of a grain (0·0007 Gm.) of phosphorus. Each official U. S. pill contains about $\frac{1}{100}$ of a grain (0·0006 Gm.).

PILULA PLUMBI CUM OPIO. Br. Pill of Lead with Opium.

(PĬL'Ů-LĄ PLŬM'BĪ CŬM Ō'PĮ-Ō.)

" Lead Acetate, in fine powder, 36 *grains* or 6 grammes; Opium, in powder, 6 *grains* or 1 gramme; Syrup of Glucose, 4 *grains* or 0·7 gramme or a sufficient quantity. Mix to form a mass. This Pill contains about 12½ per cent. of Opium." *Br.*

This pill would be better left to extemporaneous prescription, the requisite proportion of opium to the acetate varying in different cases. The tannic acid of the confection of roses decomposes a portion of the acetate; but the resulting lead tannate is not entirely inert. The mass contains about six parts of lead acetate in eight, and may be given in the dose of two or three grains (0·13 or 0·20 Gm.) to begin with.

PILULA QUININÆ SULPHATIS. Br. Pill of Quinine Sulphate.

(PĬL'Ů-LĄ QUĮ-NĪ'NÆ SŬL-PHĀ'TĬS.)

" Quinine Sulphate, 30 *grains* or 3 grammes; Tartaric Acid, in powder, 1 *grain* or 0·1 gramme; Glycerin, 4 *grains* or 0·4 gramme; Tragacanth, in powder, 1 *grain* or 0·1 gramme. Triturate the Quinine Sulphate with the Tartaric Acid; add the product to the previously mixed Glycerin and Tragacanth; make a mass." *Br.*

The reason for introducing a quinine pill mass in the British Pharm. 1898 is doubtless to serve the convenience of dispensers and to save time; tartaric acid aids in solubility and in making the pills smaller, whilst glycerin keeps the mass from undue hardening.

PILULÆ RHEI. U. S. Pills of Rhubarb.

(PĬL'Ů-LÆ RHĒ'Ī.)

Pilules de Rhubarbe, *Fr.;* **Rhabarberpillen,** *G.*

"Rhubarb, in No. 60 powder, *twenty grammes* [or 308 grains]; Soap, in fine powder, *six grammes* [or 93 grains]; Water, *a sufficient quantity*, To make *one hundred pills.* Beat the powders together with Water, so as to form a mass, to be divided into *one hundred pills.*" *U. S.*

Rhubarb is so often given in the pilular form, that it is convenient both for the physician and for the apothecary to have an official formula indicating the mode of preparing the pills, as well as the quantity of rhubarb to be contained in each. Soap has stood the test of long experience as a good excipient for rhubarb. If made in quantity the pills should be kept in loosely-stopped bottles. We have found rhubarb pills made with compound tincture of cardamom, without other ingredient, to answer an excellent purpose. Each official pill contains three grains (0·20 Gm.) of rhubarb.

PILULÆ RHEI COMPOSITÆ. U. S. (Br.) Compound Pills of Rhubarb.

(PĬL'Ů-LÆ RHĒ'Ī CǪM-PǑṢ'Į-TÆ.)

Pilula Rhei Composita, *Br.;* **Pilules de Rhubarbe composées,** *Fr.;* **Rhabarber und Aloepillen,** *G.*

"Rhubarb, in No. 60 powder, *thirteen grammes* [or 200 grains]; Purified Aloes, in fine powder, *ten grammes* [or 154 grains]; Myrrh, in fine powder, *six grammes* [or 93 grains]; Oil of Peppermint, *one-half cubic centimeter* [or 8 minims]; Water, *a sufficient quantity*, To make *one hundred pills.* Mix the Oil of Peppermint with the powders, then beat the mixture with Water so as to form a mass, to be divided into *one hundred pills.*" *U. S.*

"Rhubarb Root, in powder, 3 *ounces* (Imperial) or 60 grammes; Socotrine Aloes, in powder, 2½ *ounces* (Imp.) or 45 grammes; Myrrh, in powder, 1½ *ounces* (Imp.) or 30 grammes; Hard Soap, in powder, 1½ *ounces* (Imp.) or 30 grammes; Oil of Peppermint, 1½ *fl. drachms* (Imp. meas.) or 3·75 cubic centimetres; Syrup of Glucose, 2¾ *ounces* (Imp.) or 55 grammes or a sufficient quantity. Mix to form a mass." *Br.*

This is a warm tonic laxative, useful in *costiveness.* If made in quantity the pills should be kept in loosely stopped bottles. The use of glycerin favors the formation of mouldiness through the attraction of moisture, and it was replaced in the formula of the Br. Ph. 1898 by syrup of glucose. From two to four pills, or from ten to twenty grains (0·65–1·3 Gm.) of the mass, may be taken twice a day.

PILULA SAPONIS COMPOSITA. Br. Compound Pill of Soap.

(PĬL'Ů-LĄ SĄ-PŌ'NĬS CǪM-PǑṢ'Į-TĄ.)

"Opium, in powder, ½ *ounce* (Imperial) or 10 grammes; Hard Soap, in powder, 1½ *ounces* (Imp.) or 30 grammes; Syrup of Glucose, ½ *ounce* (Imp.) or 10 grammes. Mix to form a mass. This Pill contains 20 per cent. of Opium." *Br.*

This pill,* although no longer official in the U. S. P., is useful as affording the opportunity of conveniently administering opium, in a pilular and readily soluble form, in small fractions of a grain. The name was probably intended to conceal the nature of the preparation. One grain (0·065 Gm.) of Opium is contained in about five grains (0·33 Gm.) of the mass.

PILULA SCAMMONII COMPOSITA. Br. Compound Scammony Pill.

(PĬL'Ů-LĄ SCĄM-MŌ'NĮ-Ī CǪM-PǑṢ'Į-TĄ.)

Pilules de Scammonée composées, *Fr.;* **Scammoniumpillen,** *G.*

"Scammony Resin, 1 *ounce* (Imperial) or 25 grammes; Jalap Resin, 1 *ounce* (Imp.) or 25 grammes; Curd Soap, in powder, 1 *ounce* (Imp.) or 25 grammes; Tincture of Ginger, 3 *fl. ounces* (Imp. meas.) or 75 cubic centimetres. Add the Tincture of Ginger to the Soap and Resins; dissolve with the aid of slight heat; evaporate on a water-bath until the mass has acquired a suitable consistence for forming pills." *Br.*

These pills are actively purgative in doses of from five to ten grains (0·33–0·65 Gm.).

PILULA SCILLÆ COMPOSITA. Br. Compound Squill Pill.

(PĬL'Ů-LĄ SCĬL'LÆ CǪM-PǑṢ'Į-TĄ.)

Pilules de Scille composées, *Fr.;* **Meerzwiebelpillen,** *G.*

"Squill, in powder, 1¼ *ounces* (Imperial) or 25 grammes; Ginger, in powder, 1 *ounce* (Imp.) or 20 grammes; Ammoniacum, in powder, 1 *ounce* (Imp.) or 20 grammes; Hard Soap, in

* *Pilula Saponis Composita,* U. S. P. 1870. "Take of Opium, in fine powder, *sixty grains;* Soap, in fine powder, *half a troyounce.* Beat them together with water so as to form a pilular mass."

powder, 1 *ounce* (Imp.) or 20 grammes; Syrup of Glucose, 1 *ounce* (Imp.) or 20 grammes or a sufficient quantity. Mix to form a mass." *Br.*

This preparation was dropped at the 1880 revision of the U. S. Pharmacopœia.*

This is a stimulating expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of *chronic bronchitis.* From five to ten grains (0·33–0·65 Gm.) may be given three or four times a day. The preparation should be freshly made when wanted, as the squill which it contains is liable to be injured by keeping.

PIMENTA. U. S., Br. Pimenta. [Allspice.]

(PĪ-MĔN'TĄ.)

"The nearly ripe fruit of Pimenta officinalis, Lindley (nat. ord. Myrtaceæ)." *U. S.* "The dried full-grown unripe fruit of Pimenta officinalis, Lindl." *Br.*

Semen Amomi, Piper Jamaicense; Pimento, Allspice, Jamaica Pepper; Piment de la Jamaïque, Toute-épice, Piment, Poivre de la Jamaïque, *Fr.;* Englisches Gewürz, Neugewürz, Nelkenpfeffer, *G.;* Pimenti, *It.;* Pimienta de la Jamaica, *Sp.*

Pimenta officinalis. Lindl. *B. & T.* 111.—*Myrtus pimenta.* Willd. *Sp. Plant.* ii. 973.—*Eugenia pimenta.* De Cand. *Prodrom.* iii. 285.—*Pimenta acris.* Wight. *B. & T.* 110.—*Pimenta officinalis.* Berg. in Engler and Prantl. This is a beautiful tree, about thirty feet high, with a straight trunk, much branched above, and covered with a very smooth gray bark. Its dense and ever-verdant foliage gives it at all times a refreshing appearance. The leaves, which are petiolate, vary in shape and size, but are usually about four inches long, elliptical, entire, blunt or obtusely pointed, veined, and of a deep shining green color. The flowers are small, without show, and disposed in panicles upon trichotomous stalks, which usually terminate the branches. The fruit is a spherical berry, crowned with the persistent calyx, and when ripe is smooth, shining, and of a black or dark purple color. The tree exhales an aromatic fragrance, especially during the summer months, when in flower.

It is a native of the West Indies, Mexico, and South America, and is abundant in Jamaica, whence its fruit received the name of *Jamaica pepper.*† The allspice plant is cultivated in Central America and the surrounding countries, but more than half the supply to the United States comes from Jamaica, where the tree is so abundant as to form in the mountainous districts whole forests, and to require no further cultivation than the clearing out of the underbrush. The berries are gathered after having attained their full size, but while yet green, and are carefully dried in the sun. When sufficiently dry, they are put into bags and casks for exportation. The fruits of four other species of the genus Pimenta, found in Venezuela, Guiana, and the West Indies, are employed in their native countries as spices.

Properties. The berries, as they reach us, are of different sizes, usually about as large as a small pea, round, wrinkled, crowned with the short, four-parted calyx or its remnants and a short style, brownish or brownish gray, and when broken present two cells, each containing a black hemispherical or reniform seed. They have a fragrant odor, thought to resemble that of a mixture of cinnamon, cloves, and nutmeg. Hence the name of *allspice*, by which they are best known in this country. Their taste is warm, aromatic, pungent, and slightly astringent. They impart their flavor to water, and all their virtues to alcohol. The infusion is of a brown color, and reddens litmus paper. They yield a volatile oil by distillation having the sp. gr. of from 1·04 to 1·05 at 15° C. (See *Oleum Pimentæ.*) Bonastre obtained from them a volatile oil, a green fixed oil, a fatty substance in yellowish flakes, tannin, gum, resin, uncrystallizable sugar, coloring matter, malic and gallic acids, saline matters, moisture, and lignin. The green oil has the burning aromatic taste of pimenta, and is supposed to be the acrid principle. Upon this, therefore, together with the volatile oil, the medical properties of the berries depend; and, as these two principles exist most largely in the shell or cortical portion, this part is most efficient. According to Bonastre, the shell contains 10 per cent. of the volatile and 8 of the fixed oil, the seeds only 5 per cent. of the former and 2·5 of the latter. Berzelius considers the green fixed oil of Bonastre as a mixture of volatile oil, resin, fixed oil, and perhaps a little chlorophyll. Dragendorff in 1871 announced the existence of an alkaloid in allspice. It is present in exceedingly small quantity, and has somewhat the odor of coniine. Mr. W. W. Abell obtained from 448 Gm. of pimenta leaves one-half of one per cent. of volatile oil resembling

* "Take of Squill, in fine powder, *twelve grains;* Ginger, in fine powder, Ammoniac, in fine powder, each, *twenty-four grains;* Soap, in fine powder, *thirty-six grains;* Syrup *a sufficient quantity.* Mix the powders together; then beat them with Syrup so as to form a pilular mass, to be divided into twenty-four pills." *U. S.* 1870.

† *Pimienta de Tabasco, Tabago* or *Mexican Allspice,* is larger and somewhat less aromatic than the *Jamaica* or true allspice.

oil of bay; he also found tannic acid. (*A. J. P.*, 1886, 163.) A convention of hygienists at Vienna decided that ground allspice should not yield more than 6 per cent. of ash, of which not more than 0·5 per cent. should be soluble in hydrochloric acid.

The pimenta is sometimes adulterated by the larger and less aromatic berries of the Mexican *Myrtus tobasco*. (Mocino.)

Medical Properties and Uses. Pimenta is an aromatic spice, used in medicine chiefly as an adjuvant to tonics and purgatives. It is particularly useful in cases attended with much *flatulence*. It is, however, much more largely employed as a condiment than as a medicine. The dose is from ten to forty grains (0·65–2·6 Gm.).

PIPER. U. S. (Br.) Pepper. [Black Pepper.]

(PĪ'PĘR.)

"The unripe fruit of Piper nigrum, Linné (nat. ord. Piperaceæ)." *U. S.* "The dried unripe fruit of Piper nigrum, Linn." *Br.*

Piper Nigrum, *Br.*, Poivre noir (commun), Poivre, *Fr.;* Schwarzer Pfeffer, *G.;* Gemeine Peper, *Dutch;* Pepe nero, *It.;* Pimienti negra, *Sp.;* Fifil uswud, *Arab.;* Lada, *Malay;* Maricha, *Jav.;* Sahan, *Palembang.*

Piper nigrum. L. *Sp. Pl.* (1753) 28; Willd. *Sp. Plant.* i. 159; Carson, *Illust. of Med. Bot.* ii. 38, pl. 83; *B. & T.* 245. The pepper vine is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad-ovate, acuminate, seven-nerved, coriaceous, very smooth, of a dark green color, and attached by strong sheath-like footstalks to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical spadix, and succeeded by globular berries, which are red when ripe.

The plant grows wild in Cochin-China and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Java, Borneo, the Philippines, and many other places in the East; also to some extent in the West Indies. The cultivation of black pepper is said to be on the decline in Siam, but to be rapidly increasing in Borneo, one thousand tons having been exported from Sarawak in 1889. The best pepper is affirmed to be produced in Malabar; but Europe and America derive their chief supplies from Sumatra and Java. The plant is propagated by cuttings, and is supported by props, or trees planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The plant sometimes begins to bear as early as the first year after planting, increases in its yield to the fifth or sixth year, when it produces eight or ten pounds, and begins to lose its productiveness about the fifteenth year. The berries are gathered so soon as one is seen to turn red,—*i.e.*, before they are all perfectly ripe,—and, upon being dried, become black and wrinkled. The greatest production is in Sumatra, and the ports of export are principally Singapore and Penang, the Malabar pepper coming from Tellicherry. Our imports are principally through England, and not direct, and it seems that in England, at least, it is customary to mix peppers of different origin in grinding, taking Malabar for weight, Penang for strength, and Sumatra for color. (*Bulletin U. S. Dept. of Agric.*, No. 13, 1887.) The importations of unground peppers for the year 1896 were 16,644,763 lbs., valued at $650,861, and for 1897, 15,033,452 lbs., valued at $711,453.

White pepper is the ripe berry, deprived of a part of its pericarp by maceration in water and subsequent friction, and afterwards dried in the sun. It has less of the peculiar virtues of the spice than has the black pepper, and is seldom employed.

Piper longum, which was at one time official, differs from its congeners in having its lower leaves cordate, petiolate, from five- to seven-nerved, its upper oblong-cordate, sessile, and five-nerved; its flowers in dense, short, terminal, and nearly cylindrical spikes; and its fruit, consisting of very small one-seeded berries or grains, embedded in a pulpy matter. It is a native of Southeastern Asia, and is produced abundantly in Bengal and other parts of Hindostan. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant, and dried in the sun. *Long pepper*, as the fruit is called, is cylindrical, an inch or more in length, indented on its surface, of a dark-gray color, a weak aromatic odor, and a pungent fiery taste. M. Dulong found its chemical composition to be closely analogous to that of black pepper. Like that, it contains *piperin*, a concrete oil or soft resin upon which its burning acrimony depends, and a volatile oil to which it probably owes its odor. Its medical virtues are essentially the same as those of black pepper; but it is inferior to that spice, and is seldom used. *West African* or *Ashantee Pepper* is the berry of *P. clusii*, which grows abundantly in tropical Africa.

It does not come into Western commerce, although much used in Africa. The berry is described as resembling cubebs, but less rugose, and with a more slender pedicel, and having the odor and taste of black pepper. Stenhouse found piperin in this variety of pepper.

Properties. The dried berries are about as large as a small pea, externally blackish, reticulated, and wrinkled, internally whitish, hollow, and with an undeveloped embryo, of an aromatic smell, and a hot, pungent, almost fiery taste.* They yield their virtues partially to water, entirely to alcohol and ether. Pelletier found them to contain a peculiar principle called *piperin*, an acrid concrete oil or soft resin of a green color, a balsamic volatile oil, isomeric with oil of turpentine, a colored gummy substance, an extractive matter like that found in leguminous plants capable of being precipitated by infusion of galls, starch, a portion of bassorin, tartaric and malic acids, lignin, and various salts. (See *Piperinum.*) William Johnston (König's *Nahrungs- und Genussmittel*, 3d ed., Bd. i. 1046) finds that *piperidine*,† $C_5H_{11}N$, is an invariable constituent of pepper in amounts varying from 0·21 to 0·77 per cent. (See p. 1053.)

The taste and medicinal activity of pepper depend mainly on the concrete oil or resin, and on the volatile oil. The concrete oil is of a deep green color, very acrid, and soluble in alcohol and ether. The volatile oil is limpid, colorless, becoming yellow by age, of a strong odor, and of a taste less acrid than that of pepper itself. Its formula is $C_{10}H_{16}$, and it forms a liquid but not a solid compound with hydrochloric acid. According to Weigle (*Apoth. Zeit*, 1893, 626), pepper contains, besides cellulose, starch, and coloring matter,—1. Volatile oil, smelling strongly of pepper, but without pungency; 2. A thick oil, tasteless and nearly odorless; 3. Odorless piperin, whose solutions possess the pungency of pepper. Weigle believes that in the fresh fruit the volatile oil acts as a solvent for the piperin, and he thus accounts for their pungency.

The following are analyses of commercial peppers made by Blyth (*Foods: their Composition and Analysis*, 1882, 496):

	Hygroscopic Moisture.	Piperin in Pepper dried at 100° C.	Resin in Pepper dried at 100° C.	Aqueous Extract in Pepper dried at 100° C.	Ash in Pepper dried at 100° C.	
					Soluble in Water.	Total.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Penang	9·53	5·57	2·08	18·33	2·21	4·18

Long pepper	. . .	1·80	0·80	16·82	4·47	8·30

Medical Properties and Uses. Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been employed as a condiment in medicine. Its chief medicinal application is to excite the languid stomach and correct *flatulence*. It was long since occasionally administered for the cure of *intermittents;* but its employment for this purpose had passed from the profession to the vulgar, till a few years since revived by an Italian physician, to be again consigned to forgetfulness. Piperin has also been employed in the same complaint, and has even been thought superior to quinine sulphate;

* The powder of pepper is frequently adulterated with various substances, which can be detected by the microscope. (See *P. J. Tr.*, June, 1860; also *Bulletin U. S. Dept. of Agric.*, No. 13, Part II., pp. 183–209, 1887.) The characteristic starch granule is stated to be compound, preserving the form of the cell containing it. (Bouchardat, *Ann. de Thérap.*, 1874.) *Poivrette* or *pepperette* is a pale yellow, buff, or cream-colored powder, which is said to be largely sold for the purpose of adulterating powdered pepper. According to the researches of Prof. J. C. Brown, it is probably ground olive stones. (See *A. J. P.*, 1887, p. 146.) The ash of a pepper, ground or unground, should never amount to more than 6 per cent.

† According to the experiments of F. W. Tunnicliffe (*Centralb. f. Phys.*, 1897), the injection of from 0·01 to 0·02 Gm. of the piperidine chloride will produce in a cat of about three kilogrammes' weight an enormous rise of the arterial pressure, due to narrowing of the blood-paths. This is in accord with the investigations of B. Moore and R. Row (*Journ. Physiol.*, London, 1898), who find that piperidine produces paralysis of the intra-muscular part of the motor nerve, and, whilst slowing the heart, increases enormously the arterial pressure chiefly by causing a constriction of the arterioles by an action upon the peripheral ganglia; in this, as in other ways, resembling in its physiological effects coniine and nicotine. The authors believe that this similarity is due to the presence of a reduced pyridine ring in each molecule, and, further, that the intensification of the action is caused by the introduction of an organic radical as a side group into this ring.

but experience has not confirmed this favorable opinion. That, in its impure state, when mixed with a portion of the acrid principle, it will occasionally cure intermittents, there can be no doubt; but it is not comparable to the preparations of bark, and is certainly less active than the official oleoresin of pepper. In intermittent fever, pepper may be found a useful adjuvant to the more powerful febrifuge. The dose of pepper is from five to twenty grains (0·33–1·3 Gm.). It may be given whole or in powder, but is more energetic in the latter state. Dose of piperin, from one to six grains (0·065–0·4 Gm.).

PIPERINUM. U. S. Piperin.

$C_{17}H_{19}NO_3$; 284·38. (PĪ-PĔ-RĪ'NŬM.) $C_{17}H_{19}NO_3$; 285.

"A neutral principle obtained from pepper, and obtainable also from other plants of the natural order Piperaceæ." *U. S.*

It will be observed that the official title of this principle has been changed in the U. S. P. 1890 to "Piperinum," thus taking it out of the class of alkaloids and placing it among the neutral principles. It has never been claimed by chemists that piperin had all the properties of the alkaloids as a class; it was described as a "principle of feebly alkaloidal power" in the U. S. P. 1880, and this should have been retained at least until it had been proved beyond question that this description was incorrect.

Piperin was discovered by Professor Œrsted, of Copenhagen, who considered it to be the active principle of pepper. Pelletier, however, denied its medical activity, and ascribed all the effects supposed to have been obtained from it to a portion of the acrid concrete oil with which it is mixed when not very carefully prepared. It is obtained by treating pepper with alcohol, evaporating the tincture to the consistence of an extract, submitting the extract to the action of an alkaline solution by which the oleaginous matter is converted into soap, washing the undissolved portion with cold water, separating the liquid by filtration, treating the matter left on the filter with alcohol, and allowing the solution thus obtained to evaporate spontaneously, or by a gentle heat. Crystals of piperin are deposited, and may be purified by alternate solution in alcohol or ether, and crystallization. Piperin may be regarded as a *piperidine*, $C_5H_{11}N$, in which one H is replaced by the radical of *piperic acid*, thus: $C_5H_{10}N.C_{12}H_9O_3$. Piperin does not yield salts with acids. (*Buchner's Neues Rep.; A. J. P.*, Oct. 1876.) Rügheimer (*A. J. P.*, Aug. 1882, 397) has regenerated piperin by the union of piperidine and the chloride of the radical of piperic acid, thus making piperin artificially. The properties of this artificial principle are identical with those of the natural piperin.*

Piperidine is a powerful volatile alkaloid, soluble in all proportions in water and alcohol, and forming crystalline salts with acids. It is one of the decomposition products of piperin, and is of great chemical interest as being a simple derivative of pyridine, C_5H_5N, which seems to underlie the molecular structure of so many alkaloids. Piperidine is *hexahydropyridine*, $C_5H_{11}N$, and can be easily obtained from pyridine by the action of tin and hydrochloric acid, or when sodium acts upon the alcoholic solution. Conversely, piperidine can be changed into pyridine when sulphuric acid at 300° C. or gentle oxidizing agents act upon it. Coniine, it will be remembered (see *Conium*), has been shown synthetically to be a normal propylpiperidine.

Properties. When perfectly pure, piperin is in colorless transparent crystals, without taste, with no perceptible action on litmus paper, and fusible at 128° to 129·5° C. (262·4° to 265° F.) (Rügheimer, *A. J. P.*, Aug. 1882, p. 397), capable of being sublimed under favorable circumstances in perfect crystals (Waddington, *P. J. Tr.*, March, 1868, p. 415), insoluble in cold water, slightly soluble in boiling water which deposits it upon cooling, soluble in alcohol, ether, and acetic acid, and still more readily in chloroform, benzol, and petroleum spirit, decomposed by the concentrated mineral acids, with sulphuric becoming of a blood-red color, with nitric first of a greenish yellow, then orange, and ultimately red. As ordinarily procured,

* *Heliotropin.* (*Piperonal.*) This interesting substance, although used almost exclusively in perfumery, has been recommended by Fraggani (*Pharm. Centralhalle*, xxviii. 253) as an antiseptic and antipyretic. It may be obtained by the oxidation of piperic acid, as follows. Piperin is made to yield potassium piperate by boiling it for twenty-four hours with an equal part of potassa and 5 parts of ordinary alcohol. This is then dissolved in 40 to 50 parts of hot water, and the hot solution slowly mixed, under constant stirring, with a solution of 2 parts (that is, twice the weight of the sodium piperate) of potassium permanganate. The resulting magma is put on a strainer and repeatedly washed with hot water, until it no longer has the characteristic odor of heliotropin. The united liquids are now distilled, and from the first portions of the distillate which are caught separately, the larger portion of the heliotropin or rather piperonal ($C_8H_6O_3$) separates, on cooling, in crystals; the remainder may be obtained by shaking the distillate with ether. (*Chem. Zeitung*, 1884.) This piperonal is the aldehyde of piperonylic acid, $C_6H_3(COOH)\overset{O}{\underset{O}{>}}CH_2$, which, as the formula indicates, is the methylene ester of protocatechuic acid, $C_6H_3COOH(OH)_2$.

the crystals are yellow. Piperin is generally believed to be a weak alkaloid of the formula $C_{17}H_{19}NO_3$. When boiled with strong potash or heated with soda-lime it is converted into *piperic acid*, $C_{10}H_{12}O_4$, and *piperidine*, $C_5H_{11}N$.

It is officially described as "colorless, or pale yellowish, shining, prismatic crystals, odorless, and almost tasteless when first put in the mouth, but on prolonged contact producing a sharp and biting sensation. Permanent in the air. Almost insoluble in water; soluble in 30 parts of alcohol at 15° C. (59° F.), and in 1 part of boiling alcohol; very soluble in hot acetic acid; only slightly soluble in ether. When heated to 130° C. (266° F.), Piperin melts; upon ignition it emits alkaline vapors, and is consumed, leaving no residue. The alcoholic solution of Piperin is neutral to litmus paper. Concentrated sulphuric acid dissolves Piperin with a dark blood-red color, which disappears on dilution with water. When treated with nitric acid, Piperin turns rapidly first orange and then red, and the acid acquires a yellow color, deepening to reddish as the crystals dissolve. On adding to this solution an excess of potassium hydrate test-solution, the color is at first yellow, but upon boiling it becomes blood-red." *U. S.*

Medical Properties. (See *Piper*, p. 1051.)

PIX BURGUNDICA. U. S., Br. Burgundy Pitch.

(PĬX BŬR-GŬN'DĬ-CĂ.)

"The prepared resinous exudation of Abies excelsa, Poiret (nat. ord. Coniferæ)." *U. S.* "The resinous exudation obtained from the stem of Picea excelsa, Link., melted and strained." *Br.*

Poix de Bourgogne, Poix jaune, Poix blanche, *Fr.;* Burgundisches Pech, Burgunder Harz, Wasserharz, *G.*

The Coniferæ have been divided by Eichler, in Engler and Prantl's work, into the following suborders,—viz., *Pinoideæ*, or Conifers proper, and *Taxoideæ*. Eichler does not consider that these subdivisions are deserving of family distinction, as indicated by Lindley and followed by Britton and Brown in their Flora. The genus Pinus of Linnæus has been divided into the following genera: *Pinus* (the Pines), *Larix* (the Larches), *Picea* (the Spruces), *Tsuga* (the Hemlocks), and *Abies* (the Firs).

Abies excelsa. De Candolle.—*A. communis.* Loudon's *Encyc. of Plants.*—*Pinus abies.* Willd. *Sp. Plant.* iv. 506; Woodv. *Med. Bot.* p. 4, t. 2.—*Pinus picea.* Du Roi. *B. & T.* 261. The *Norway spruce* is a lofty tree, rising sometimes one hundred and fifty feet in height, with a trunk from three to five feet in diameter. The leaves, standing thickly upon the branches, are short, obscurely four-cornered, often curved, of a dusky green color, and shining on the upper surface. The male aments are purple and axillary, the female of the same color, but usually terminal. The fruit is in pendent, purple, nearly cylindrical strobiles, the scales of which are oval, pointed, and ragged at the edges.

This tree is a native of Europe and Northern Asia. Though designated as the source of Burgundy pitch, it furnishes but a part of the substance sold under that name. Tingley asserts that the real Burgundy pitch is obtained from the *Abies picea*, or European silver fir tree. According to Geiger, who is probably correct, it is procured from both species. To obtain the *pitch*, portions of the bark are removed so as to lay bare the wood, or perpendicular grooved channels are cut, and the flakes of concrete resinous matter which form upon the surface of the wound, having been detached by iron instruments, are melted with water in large boilers, and then strained through coarse cloths. It is called Burgundy pitch from the province of that name in the east of France, although whether it was ever produced in that province is uncertain. It is chiefly collected in Finland, the Schwarzwald, Austria, and the Bernese Alps.

From various species of pine, in different parts of Europe, a similar product is obtained and sold by the same name. It is prepared by removing the juice which concretes upon the bark of the tree, or upon the surface of incisions, called *galipot* by the French, and purifying it by melting, and straining either through cloth or a layer of straw. A *factitious Burgundy pitch* is made by melting together common pitch, rosin, and turpentine, and agitating the mixture with water, which gives it the requisite yellowish color. Its odor is different from that of the genuine. Mr. Hanbury gives as a test of true Burgundy pitch that it is almost entirely soluble in twice its weight of glacial acetic acid, while the factitious article similarly treated forms a turbid mixture, quickly separating into a thick oily liquid above, and a bright solution below.*

* The resinous exudation from *Pinus sylvestris* is sometimes offered as Burgundy pitch, but Herr Hirschson (*Pharm. Zeit. f. Russl.*, xxiv.) states that it is possible to distinguish the resin of *Pinus picea* by its being only partially soluble in ether, chloroform, and solutions of salts of ammonium, sodium carbonate, and borax, which dissolve completely the resin of *Pinus sylvestris*. The resin of *Pinus picea* is also precipitated by the addition of water from its sulphuric acid solution in red violet flakes, whilst *Pinus sylvestris* resin precipitates white.

As brought to this country, Burgundy pitch is generally mixed with impurities, which require that it should be melted and strained before being used. In its pure state it is "hard, yet gradually taking the form of the vessel in which it is kept; brittle, with a shining, conchoidal fracture, opaque or translucent, reddish-brown or yellowish-brown, odor agreeably terebinthinate; taste aromatic, sweetish, not bitter. It is almost entirely soluble in glacial acetic acid, or in boiling alcohol, and partly soluble in cold alcohol." *U. S.* It is very fusible, and at the heat of the body softens and becomes adhesive. It differs from turpentine in containing a smaller proportion of volatile oil. Instead of the sylvic acid of colophony resin, it contains an isomeric acid, which has been called *pimaric acid*, melting at 148°–149° C., difficultly soluble in cold but readily soluble in boiling alcohol, and also soluble in ether. According to Perrenoud, its formula is $C_{40}H_{54}O_4$, but Vesterberg (*Ber. der Chem. Ges.*, 1885, p. 3331) showed it to be a mixture, and has since (*Ibid.*, 1886, p. 2167, and 1887, p. 3248) prepared from it two isomeric crystalline acids, a *dextropimaric acid* and a *lævopimaric acid*, both of the formula $C_{20}H_{30}O_2$; with these is mixed a varying amount of an amorphous resin acid known as *pinic acid*.

Medical Properties and Uses. Applied to the skin, in the shape of a plaster, Burgundy pitch acts as a gentle rubefacient, producing a slight inflammation without separating the cuticle. Sometimes it excites a papillary or vesicular eruption; and we have known it to act as a violent irritant, giving rise to severe pain, swelling, and redness, followed by vesication and even ulceration. It is used chiefly in chronic *rheumatic pains*, and in chronic affections of the chest or abdomen, which call for a gentle but long-continued revulsion to the skin.

PIX CARBONIS PRÆPARATA. Br. Prepared Coal Tar.

(PĬX CĂR'BŌ-NĬS PRÆ-PĄ-RĀ'TĄ.)

"Prepared by placing commercial coal tar in a shallow vessel, and maintaining it at a temperature of 120° F. (48·9° C.) for one hour, stirring frequently." *Br.*

Prepared Coal Tar was introduced into the Br. Pharm. 1898; it is the chief constituent in the preparation of *Liquor Picis Carbonis.* (See p. 813.) It has no other use in medicine.

PIX LIQUIDA. U. S., Br. Tar.

(PĬX LĬQ'UĮ-DĄ—lĭk'wę-dą.)

"An empyreumatic oleoresin obtained by the destructive distillation of the wood of Pinus palustris, Miller, and of other species of Pinus (nat. ord. Coniferæ)." *U. S.* "A bituminous liquid, obtained from the wood of Pinus sylvestris, Linn., and other species of Pinus, by destructive distillation. Known in commerce as Stockholm tar." *Br.*

Resina Empyreumatica Liquida; Goudron végétal, Goudron, *Fr.;* Theer, *G.;* Pece liquida, *It.;* Alquitran, *Sp.*

The tar used in this country is prepared from the wood of various species of pine, particularly *Pinus palustris* of the Southern States. (See *Terebinthina.*) The dead wood is usually selected, because, when vegetation ceases, the resinous matter becomes concreted in the interior layers. The wood is cut into billets of a convenient size, which are placed together so as to form a large stack or pile and then covered with earth as in the process for making charcoal. The stack is built upon a small circular mound of earth previously prepared, the summit of which gradually declines from the circumference to the centre, where a cavity is formed, communicating by a conduit with a shallow ditch surrounding the mound. Fire is applied through an opening in the top of the pile, and a slow combustion is maintained, so that the resinous matter may be melted by the heat. This runs into the cavity in the centre of the mound, and passes thence by the conduit into the ditch, whence it is transferred into barrels. Immense quantities of tar are thus prepared in North Carolina and the southeastern parts of Virginia, sufficient, after supplying our own consumption, to afford a large surplus for exportation.* Considerable quantities of tar have been prepared also in the lower parts of New Jersey, in some portions of New England, and in Pennsylvania west of the Alleghany Mountains, from the *Pinus rigida*, or pitch pine, and perhaps from some other species.

Properties. Tar has an acid reaction, a peculiar empyreumatic odor, a bitterish, resinous, somewhat acrid taste, a color almost black, and a tenacious consistence intermediate between that of a liquid and that of a solid. By age it becomes granular and opaque. It consists of res-

* According to R. J. Dunwoody (*A. J. P.*, 1889), tar is also prepared on a small scale by wedging vertically into an iron pot the pieces of split wood, inverting over the projecting ends another iron pot, and setting fire to the wood; or by simply placing the billets of wood on the top of an inclined plane of sheet iron, setting the wood on fire, and catching the tar which runs down.

inous matter, united with acetic acid, oil of turpentine, and various volatile empyreumatic products, and colored with charcoal. By distillation it yields an acid liquor called *pyroligneous acid* (see *Acidum Aceticum*), and an empyreumatic oil called *oil of tar;* what is left behind is *pitch.* It is described in the Br. Ph. as "A dark brown or blackish semi-liquid substance, of a peculiar aromatic odor. The specific gravity varies from 1·02 to 1·15. *Water* agitated with it acquires a pale-brown color, sharp empyreumatic taste, and acid reaction, and with dilute *test-solution of ferric chloride* assumes a red color. Tar is completely soluble in ten times its volume of *alcohol* (90 per cent)." The empyreumatic oil was first examined by Dr. Reichenbach, of Moravia, who found a variety of substances, to which he gave the names of *paraffin*, *eupion*, *creosote*, *picamar*, *capnomor*, and *pittacal.* It has been found by more careful study of wood-tar that it contains a great variety of compounds, including the hydrocarbons *toluene*, C_7H_8, *xylene*, C_8H_{10}, *mesitylene* and *pseudocumene*, C_9H_{12}; phenols like common *phenol*, C_6H_6O, *cresol*, C_7H_8O, *guaiacol*, $C_7H_8O_2$, *creosol*, $C_8H_{10}O_2$, *phlorol*, $C_8H_{10}O$, and *methylcreosol*, $C_9H_{12}O_2$, the last four constituting the mixture known as creosote; and, lastly, *paraffin* in variable quantity, depending upon the temperature of distillation, *naphtalene*, $C_{10}H_8$, *pyrene*, $C_{16}H_{10}$, *chrysene*, $C_{18}H_{12}$, and *retene*, $C_{18}H_{18}$. *Pyrocatechin*, $C_6H_4(OH)_2$, is also obtained, either in the pyroligneous acid, as it is soluble in water, or in the tarry mixture. It crystallizes readily, fuses at 104° C. (219·2° F.), and sublimes at a temperature slightly above this. Tar yields a small proportion of its constituents to water, which is thus rendered medicinal, and is employed under the name of *tar water.* Tar water is of "a pale yellowish-brown color and an acid reaction, yields with ferric chloride test-solution a transient green color, and is colored brownish-red by an equal volume of calcium hydrate test-solution." Tar is dissolved by alcohol, ether, chloroform, and the volatile and fixed oils, and by a solution of potassa or soda. On spreading tar in a thin layer on a pane of glass it should present a homogeneous appearance. Those specimens which contain granular transparent masses should be rejected. These masses, which polarize brilliantly, are said to be *pyrocatechin.* Tar should have a specific gravity of 1·03 to 1·07; it should boil at from 25° to 40° C. Its reaction should be acid. "*Steam refined tar*" is tar which has been simply heated in steam caldrons and strained to remove foreign impurities.

Hirschsohn has suggested the following plan for the identification of different varieties of tar. **I. Completely soluble in 95 per cent. acetic acid.** *Pine Tar.*—French turpentine dissolves it completely. The petroleum ether extract of the tar is colored greenish when shaken with a dilute solution of cupric acetate (1 : 1000). Chloroform and absolute ether dissolve it completely. *Beech Tar.*—Turpentine oil dissolves it only partially. The petroleum ether extract is not colored by copper acetate solution. Chloroform and absolute ether do not entirely dissolve it. **II. Not completely soluble in 95 per cent. acetic acid.** *Juniper Tar.*—Turpentine oil dissolves it completely. Aniline dissolves it completely. The aqueous extract (1 : 20) yields a red coloration with dilute solution of ferric chloride (1 : 1000). *Birch Tar.*—Turpentine oil dissolves it completely. Aniline does not dissolve it completely. The aqueous extract is colored greenish by ferric chloride. Turpentine oil dissolves it only partially. *Aspen Tar.*—Benzol, chloroform, absolute ether, and olive oil dissolve it only partially. (*Ph. Ztg.*, 97, 396; *Ph. Zts. Russl.*, 97.)

The pitch left after the evaporation of tar was formerly official with the British Colleges, under the names of *Pix nigra*, *Pix arida*, or simply *Pix.* It has a shining fracture, softens and becomes adhesive with a moderate heat, melts in boiling water, and consists of the unaltered resin of the pine and of various empyreumatic resinous products which have received the name of *pyretin.* (Berzelius, *Traité de Chimie*, vi. 641, 680.) It has been used internally in *ichthyosis* and other cutaneous diseases, and in *piles.* The dose is from ten grains to a drachm (0·65–3·9 Gm.), given in pill. Pitch is also used externally in the form of ointment.

Medical Properties and Uses. The medical properties of tar are similar to those of the turpentines, but it is much less irritant. It is occasionally used with advantage in *chronic catarrhal affections*, and in *complaints of the urinary passages.* Little benefit can be expected from it in genuine *phthisis*, in the treatment of which it was formerly recommended. In reference to the administration of tar, it has always been considered desirable to have it in a soluble state, so that it might be brought with facility into a liquid form if required. Besides, tar in the stomach will probably be found efficacious in proportion to its solubility. This desired end was attained when it was discovered that tar was capable of forming a definite, solid compound with sugar which was very soluble in water. Saccharated tar contains 4 per cent. of pure tar, resembles sugar in appearance, having a sweet taste and the odor of tar, and may be given in substance or solution as deemed desirable. (*P. J. Tr.*, Sept. 1871.) (See *Syrupus*

Picis Liquidæ.)* But glycerin is a more convenient vehicle; and Glycerite of Tar was an official preparation in 1870. Its vapor, inhaled into the lungs, may be serviceable in *chronic bronchitis* and *phthisis*. Its effects are most conveniently obtained by placing tar or the oil of tar in a tin dish containing hot water, and heating this; the fumes may be inhaled by inverting a funnel over the dish, to which a rubber tube is attached. Externally applied it is a decided stimulant, and in the state of ointment is a very efficient remedy in *tinea capitis* or *scaldhead*, and in some cases of *psoriasis*, in *chronic eczema*, and other *affections of the skin*.† Some prefer a mixture with glycerin in the form of the formerly official Glycerite of Tar.

It may be used in the form of tar water (see *Infusum Picis Liquidæ*), or in substance made into pills with wheat flour, or mixed with sugar in the form of an electuary. The dose is from half a drachm to a drachm (1·9–3·75 C.c.), and may be repeated so as to amount to three or four drachms (11·25–15 C.c.) daily.

Pulverulent tar is prepared by M. Magnes-Lahens, by mixing, in an earthen-ware vessel, two parts of finely divided charcoal and one part of liquid tar. The resulting mixture resembles small grains of gunpowder, does not soil the vessel or the fingers, and yields readily to water the tar which it contains,—the most favorable temperature for solution being about 20° C. (68° F.). M. Magnes-Lahens recommends a syrup prepared from the powder as follows. Take of pulverulent tar 50 Gm., water 180 Gm., granulated sugar 320 Gm. Mix the tar and sugar in a mortar, then add the water, and heat the mixture by a water-bath at 60° C. (140° F.). Then remove from the bath, shake until the sugar is all dissolved, and strain when hot, and afterwards again when cold. A tablespoonful of the syrup, added to a tumbler of water, yields a tar water resembling that of the French Codex. The pulverulent tar may also be used for pills, and for fumigation by throwing a few grains on a heated shovel. (*P. J. Tr.*, April, 1872, 850.)

PLUMBUM. Lead.

Pb; 206·4. (PLŬM'BŬM.) Pb; 206·5.

Plomb, *Fr.*; Blei, *G.*; Lood, *Dutch*; Piombo, *It.*; Plomo, *Sp.*; Chumbo, *Port.*

Lead is not official in its metallic state, but enters into a number of important medicinal preparations. It occurs in nature as an oxide, as a sulphide called *galena*, and in saline combination, forming the native lead sulphate, phosphate, carbonate, chromate, molybdate, tungstate, and arsenate. The oxide is rare, but galena is exceedingly abundant, and is the ore from which nearly all the lead of commerce is extracted. The extraction is effected either by melting the ore in contact with charcoal, or, in the case of pure galenas, by what is termed the *air reduction* process. In this case the galena is first roasted, when it is in part changed into oxide, PbO, and sulphate, $PbSO_4$. The doors of the furnace are then closed, and the unchanged sulphide reacts with both the oxide and the sulphate as follows:

$$2PbO + PbS = 3Pb + SO_2, \quad PbSO_4 + PbS = 2Pb + 2SO_2,$$

whereby all the lead is obtained in the metallic state. Lead is also successfully obtained by electrolysis directly from the galena. This is reduced at the cathode of an electrolytic cell, while hydrogen sulphide is formed at the same time and may be collected or burned to form sulphur dioxide, which is then utilized. The process is now in operation at Niagara Falls. The richest and most extensive mines of galena are found in this country. The non-argentiferous lead region of the United States extends in length from Wisconsin in the north to the Red River of Arkansas in the south, and in breadth about one hundred and fifty miles, being chiefly in the State of Missouri, while Utah, Idaho, Montana, and Colorado furnish argentiferous galena. The production of lead in the United States for the year 1896 was 254,851 short tons, of which 174,692 tons were from domestic ores; in 1897, 289,835 tons, of which 197,718 tons were from domestic ores. Nearly four-fifths of that from domestic ores was desilverized lead, and the remainder non-argentiferous lead.

Properties. Lead is a soft, bluish-gray, and very malleable metal, presenting a bright

* *Wine of Tar*, J. B. Moore. Pure Tar, ℥xvi, troy; Glycerin, Sherry Wine, Honey, āā f ℥viii; Acetic Acid, f ℥i; Boiling Water, Ovi. Mix the glycerin, sherry wine, honey, acetic acid, and boiling water together, in a stone jug or other suitable vessel of the capacity of a gallon. To the mixture add the tar, and shake the whole vigorously for several minutes. The vessel is then to be tightly stopped and placed upon a stove or in a water-bath, resting upon folds of paper, and the mixture digested, for an hour or two, at a temperature of from 150° to 160° F. During the digestion the mixture should be frequently well shaken. When the digestion is completed, the mixture is to be set aside to macerate, in a warm place, for a few days, it being well shaken occasionally during the process. Lastly, strain through muslin, and filter the strained liquid through paper.

† *Liquor Picis Alkalinus.* Dr. L. D. Bulkley, of New York, gives the following formula for this preparation, which was originally devised by his father. Tar, ℥ij; Caustic Potash, ℥j; Water, f ℥v. Mix and dissolve for external use. This mixes with water in all proportions, and only moderately discolors the skin. It dries rapidly and leaves very little stickiness. (*Medical News and Library*, June, 1873.)

surface when newly melted or cut. It has a perceptible taste, and a peculiar smell when rubbed. It undergoes but little change in the air, but is acted on by the combined influence of air and rain water, which gives rise to a hydrate, which is afterwards changed, in part, into carbonate, by absorbing carbonic acid from the atmosphere; and if in water, the carbonate is imparted to it in the state of bicarbonate, which dissolves and renders the liquid poisonous. This chemical effect on the metal is greater in proportion as the water is purer. Aqueous vapor passed through leaden pipes has a similar corroding effect, which is greater as the lead is purer. (*A. J. P.*, Nov. 1863, p. 507.) Spring and river water act on lead differently, the lead becoming slowly oxidized, and covering itself with a black coating of suboxide, which adheres strongly to the metal, and thus in some measure protects the water. (Langlois, *Journ. de Pharm. et de Chim.*, 4e sér., ii. 29.) M. Stalmann has satisfied himself, by experiment, that an extremely minute quantity of ammonia or of nitric acid will very much promote the action of water upon lead,—a millionth of ammonia being sufficient for the purpose. (*Ibid.*, iv. 467.) Metallic lead seems to be liable to the attacks of certain insects, which bore into and sometimes through it, not using it as food, but apparently in search of secure places of retreat for future development. A knowledge of this fact may sometimes be important. (*A. J. P.*, Jan. 1865, p. 72.) Its sp. gr. is 11·4, melting point 334° C. (633·2° F.), and atomic weight 206·4. Exposed to a stream of oxygen on ignited charcoal, it burns with a blue flame, throwing off dense yellow fumes. The best solvent of lead is nitric acid; but the presence of sulphuric acid destroys, and that of hydrochloric acid lessens, its solvent power, on account of the insolubility of the lead sulphate and chloride. Lead forms a suboxide, Pb_2O, a monoxide, PbO, a sesquioxide, Pb_2O_3, a dioxide, PbO_2, and a compound of the monoxide and the dioxide, which has a varying composition, but is usually Pb_3O_4. The *monoxide*, called in commerce *massicot*, or *litharge*, may be obtained by calcining, in a platinum crucible, lead subnitrate, formed by precipitating a solution of the nitrate by ammonium. On a large scale it is manufactured by exposing melted lead to the action of the air. Its surface becomes encrusted with a gray pellicle, which, being scraped off, is quickly succeeded by another; and the whole of the metal, being in this way successively presented to the air, becomes converted into a greenish-gray powder, consisting of monoxide and metallic lead. This, on exposure to a moderate heat, absorbs more oxygen, and is converted wholly into monoxide. This oxide has a yellow color, and is the only lead oxide capable of forming salts with the acids. It consists of one atom of lead and one of oxygen. *Litharge* is very much used in pharmacy, and is official in all the Pharmacopœias. (See *Plumbi Oxidum.*) The *sesquioxide*, discovered by Winckelblech, is unimportant. The *dioxide*, called also *puce* oxide, from its *flea*-brown color, may be obtained by treating red lead with nitric acid. The acid takes up the monoxide and leaves the dioxide, which may be purified by washing with boiling water. A more productive process is to precipitate four parts of lead acetate by three of sodium carbonate, and then to pass into the thin pasty mass of lead carbonate a stream of chlorine, which converts the monoxide of the carbonate into the brown dioxide. (*F. Wöhler.*) Solution of chlorinated soda may be conveniently employed to furnish the necessary chlorine. (F. F. Mayer, *A. J. P.*, 1856, p. 410.) Lead dioxide is a tasteless powder, of a dark-brown color. When heated to redness it loses half its oxygen and becomes monoxide. It consists of one atom of lead and two atoms of oxygen. The *red oxide*, Pb_3O_4, called in commerce *minium*, or *red lead*, is described under another head. (See *Plumbi Oxidum Rubrum.*) Lead combines with iodine, forming the official lead iodide. The acetate, carbonate, and nitrate are also official.

The best tests of lead are hydrogen sulphide and a solution of potassium iodide. The former produces a black precipitate of lead sulphide, the latter a yellow one of lead iodide.

Medical Properties and Uses. In concentrated form and sufficient amount the soluble preparations of lead are violent irritant poisons, producing burning in the œsophagus and stomach, soon involving the whole abdominal cavity, followed by vomiting and sometimes by purging, or more rarely by constipation. The insoluble preparations of lead are incapable of acting as acute irritant poisons, but are the common causes of subacute and chronic lead poisoning. The subacute form of the poisoning, the so-called *colica pictonum*, is very common among painters, makers of white lead, and other artisans who work in the metal. It is, however, also frequently seen in other persons, into whom the lead finds entrance in almost innumerable ways, especially with drinking-water and food. Colica pictonum usually begins with dyspeptic symptoms and obstinate constipation, associated with violent pain of a twisting character, which seems to centre round the umbilicus; the abdominal walls are spasmodically retracted, and there is even early malaise, lassitude, depression of spirits, and a failure of the general health.

The stools are whitish and scanty. A characteristic symptom is a blue line situated upon the margin of the gums where they join the teeth, due to the deposit of the lead sulphide. This blue line is usually present in all forms of subacute and chronic lead-poisoning, and is pathognomonic. It may, however, be absent even in the most severe cases.

The symptoms of chronic lead-poisoning may conform to the regular type or may be most bizarre. They are frequently, but not always, preceded by colica pictonum. The most characteristic phenomenon is the double wrist-drop, which is due to a paralysis of the extensors of the forearm, and is associated with wasting and degenerative changes in the diseased muscles. If these symptoms progress, failure of strength and anæmia gradually develop, the extensors of the leg become affected, irregular, localized, or wide-spread tracts of anæsthesia appear, and neuralgic pains occur in various parts of the body; little by little the whole muscular system becomes involved, emaciation progresses, anæmia becomes extreme, and death in a condition of cachexia ensues. Albuminuria is not a rare symptom of chronic lead poisoning; it may be due simply to the momentary irritation of the kidney, or may be the result of degenerative changes which end in complete destruction of the secreting structure, with final contraction of the organ. As the result either of primary changes in the renal organs or of a direct action of the lead upon the cerebral tissue, epileptic convulsions may occur at long intervals, or they may be associated with delirium, coma, or other evidences of cerebral disturbance. When these attacks are secondary to kidney disease they are uræmic; in saturnine cerebritis, furious convulsions, coma, and wild delirium may come on suddenly, and may prove fatal in a very few hours.

Another irregular form of lead-poisoning is that in which the symptoms exactly resemble those of gout; swelling of the joints, with pain, excessive tenderness, and even secondary degeneration of the arteries, similar to that which occurs in chronic gout, may make the likeness complete. Saturnine amaurosis, due to atrophy of the optic nerve, is a rare form of plumbism. A variety of lead-poisoning rarely spoken of in books, of which Dr. H. C. Wood has seen a number of instances, is that in which the symptoms closely resemble those of acute poliomyelitis; wide-spread paralysis scattered in different groups of muscles, with wasting and change in the electrical reactions of the affected parts, may very closely simulate the ordinary form of spinal disease, but almost invariably the true nature of the attack may be recognized by noticing that the bladder and the rectum are affected, and not rarely the occurrence of violent neuralgic pain points still more definitely to a saturnine origin.

The symptoms of lead-poisoning may also take the form of simple progressive anæmia, with failure of health and obscure nervous phenomena, such as apparently causeless neuralgic pains, wide-spread formications, insomnia, etc. The diagnosis of the true nature of an attack of lead-poisoning is of the utmost importance. In most cases it is to be readily made by noticing the blue line on the gums. When this is absent it is essential that the urine be examined chemically for lead.* As the elimination takes place irregularly and is much favored by the internal administration of potassium iodide, that salt should always be given for a few days before the examination of the urine.

* The most delicate method of testing urine for lead is that devised by Prof. Lehmann as modified by Dr. John Marshall. Concentrated hydrochloric acid is added to the urine in the proportion of 10 C.c. to 100 C.c. To the boiling mixture are added from time to time small portions (0·2 Gm.) of potassium chlorate until the liquid is of a pale straw-color and the odor of chlorine strongly perceptible. The heating is then continued without further addition of potassium chlorate until the chlorine odor disappears. On cooling, the liquid is filtered and the filtrate diluted with water until its volume equals the original volume employed. The filtrate is then placed in a glass tube of about 3·5 Cm. diameter in length, the end of the tube being covered with parchment-paper fastened with twine. (A new piece of parchment-paper should be used in each analysis, and care be taken to see that it and the twine as well as the other reagents used are free from lead.) A glass tripod on which there is a piece of platinum foil about 2·5 Cm. square attached to a platinum wire is placed in a glass vessel containing distilled water very slightly acidulated with chemically pure sulphuric acid, the liquid covering the platinum foil. The parchment tube containing the urine to be examined is then set on the foil on the tripod, the parchment-covered end being placed directly over the foil. Another piece of platinum foil, purposely cut round so as nearly to equal the calibre of the parchment-covered tube, attached at the centre to a wire (which wire, for the purpose of insulation, passes through a glass tube about twenty-five centimeters in length, and sealed at both ends), is put into the urine, so that the platinum foil in the tube, serving as a negative pole, should lie on the parchment-paper as nearly as possible over the positive platinum pole, which is under the parchment-paper on the glass tripod. The wires are connected with a battery consisting of three Grove cells. The current is kept up from one to six hours, according to the quantity of lead in the solution. A dark-gray or black deposit on the electrode in the urine indicates the probable presence of lead. The electrode upon which the deposition occurs is taken out of the urine without interrupting the electrical current, and washed by gently dipping it several times in distilled water. The foil is then placed in a small beaker, covered with nitric acid, and, after warming five or ten minutes on a water-bath, taken out, washed with distilled water, and the wash-water collected in the beaker containing the nitric acid. The nitric acid solution is evaporated to dryness, and the residue dissolved with a few drops of dilute potassium hydrate solution, and then slightly acidulated with acetic acid. The solution thus prepared was tested by special tests for lead.

The treatment of cases of acute lead-poisoning consists in the administration of alkaline carbonates, soap, soluble sulphates, sodium chloride, or other antidote, and in washing out the stomach with large draughts of water, the exhibition of castor oil or other non-irritating laxative if it be thought advisable to sweep out the intestines, and the employment of opium, counter-irritation, and the other means habitually used against toxic gastro-enteritis. In the treatment of subacute and chronic lead-poisoning the efforts are to be directed first to combating the symptoms, secondly to aiding in the elimination of the lead. The late Dr. George B. Wood was accustomed to consider alum as almost a specific remedy for the relief of painter's colic, in which disease it is also essential to employ opium for the relief of pain, and laxatives to overcome the constipation; with these latter should always be given extract of belladonna in full dose, to aid in the relaxation of the intestinal spasm. Magnesium sulphate is probably the best purgative. In chronic lead-poisoning the paralysis is to be combated by hygienic means, massage, and electricity, precisely as when it arises from other causes. Dr. H. C. Wood has seen in that form of lead-poisoning which resembles poliomyelitis the immediate arrest of progressive symptoms by the use of doses of strychnine continually increased until evidences of physiological action were obtained. For the purpose of eliminating lead from the system potassium iodide should be administered continuously for weeks and months in such doses as the stomach will bear. Warm sulphur baths are also useful.* Lead has been found in almost all the tissues of the body in fatal cases of poisoning.

In moderate dose, or in not too concentrated solution or amount, the soluble preparations of lead act as sedative astringents. When locally applied they contract relaxed vessels or tissues. When taken internally they check secretion in the alimentary canal,—according to the views of the older therapeutists, reducing the action of the heart and of the arteries, and restraining secretions generally. The insoluble preparations of lead differ therapeutically from the soluble preparations, in being free from irritant properties and acting only as feeble astringent sedatives. The preparations of lead are at present chiefly used as local applications.

Orfila has determined, by experiments on dogs, the appearance exhibited by the mucous membrane of the stomach after the use of small doses of the salts of lead. After the action of such doses for two hours, dull white points are visible on the membrane, sometimes in rows and sometimes disseminated, and evidently consisting of the metal, united with the organic tissue. If the animal be allowed to live for four days, the same spots may be seen with the magnifier; and if hydrogen sulphide be applied to the surface, they are instantly blackened. (*Archives Générales*, 3e sér., iv. 244.)

PLUMBI ACETAS. U. S., Br. Lead Acetate. [Sugar of Lead.]

$Pb(C_2H_3O_2)_2.3H_2O$; 378. (PLŬM'BĪ Ą-CĒ'TĄS.) $Pb(C_2H_3O_2)_2.3H_2O$; 378·5.

"A salt, $Pb(C_2H_3O_2)_2,3H_2O$, obtained by dissolving lead oxide or lead carbonate in acetic acid." *Br.*

Plumbi Aceticum, *P. G.;* Acetas Plumbicus, Saccharum Saturni, Cerussa Acetata; Acétate de Plomb, Sucre de Plomb, Sel de Saturne, *Fr.;* Essigsaures Bleioxyd, Bleizucker, *G.;* Zucchero di Saturno, *It.;* Azucar de Plomo, *Sp.*

Preparation. Lead acetate is obtained by two methods. By one method, thin plates of lead are placed in shallow vessels filled with distilled vinegar, in such a manner as to have a part of each plate rising above the vinegar; and these are turned from time to time, so as to bring different portions of the metallic surface in contact with the air. The metal, in the presence of the oxygen of the air, dissolves in the vinegar to saturation, and the solution is evaporated to the point of crystallization. This process is a slow one, but furnishes a salt which is perfectly neutral. The other method consists in dissolving, by the assistance of heat, litharge, or lead protoxide obtained by calcination, in an excess of distilled vinegar or of purified pyroligneous acid, contained in leaden boilers. The oxide is quickly dissolved, and, when the acid has become saturated, the solution is transferred to other vessels to cool and crystallize. The crystals having formed, the mother-waters are decanted, and, by evaporation, made to yield a new crop. These are generally yellow, but may be rendered white by repeated solutions and crystallizations.

* Warm *sulphuretted baths* are useful, formed by dissolving four ounces of potassium sulphide in thirty gallons of water, in a wooden tub. These baths cause discoloration of the skin, from the formation of lead sulphide, and should be repeated every few days, until this effect ceases to be produced. During each bath the patient should be well washed with soap and water with the aid of a flesh-brush, in order to remove the discoloration. By proceeding in this way, the lead on the skin, or in its pores, is rendered insoluble and inert, and at the same time removed.

Lead acetate is extensively manufactured in Germany, Holland, France, and England, as well as in the United States. It is principally consumed in the arts of dyeing and calico-printing, in which it is employed to form, with alum, aluminum acetate, to act as a mordant.

Properties. "Colorless, shining, transparent, monoclinic prisms or plates, or heavy, white, crystalline masses, or granular crystals, having a faintly acetous odor, and a sweetish, astringent, afterwards metallic taste. Efflorescent, and absorbing carbon dioxide, on exposure to the air. Soluble, at 15° C. (59° F.), in 2·3 parts of water, and in 21 parts of alcohol; in 0·5 part of boiling water, and in 1 part of boiling alcohol. When heated to 40° C. (104° F.), the salt loses its water of crystallization (14·25 per cent.). It fuses at 200° C. (392° F.) with the loss of acetic acid, and, when strongly heated, it is completely decomposed, with the evolution of carbon dioxide and acetone, leaving a residue of finely divided metallic lead mixed with oxide and carbonate. On heating the salt with sulphuric acid, vapors of acetic acid are evolved. The aqueous solution of the salt has a slightly acid reaction, and yields a black precipitate with hydrogen sulphide test-solution, a yellow one with potassium iodide test-solution, and a white one with diluted sulphuric acid. A 10-per-cent. solution of the salt, prepared with water which has recently been boiled, should be clear, or only slightly opalescent (limit of *carbonate*), and should yield, with potassium ferrocyanide test-solution, a pure white precipitate (absence of *iron* or *copper*). If to the aqueous solution hydrochloric acid be added until no further precipitate is produced, and the remainder of the lead removed from the filtrate by hydrogen sulphide, a portion of the new filtrate should not be affected by the addition of a slight excess of ammonia water (absence of *zinc* or *iron*). If another portion of the last filtrate be evaporated to dryness, it should leave no residue (absence of salts of the *alkalies* or of *zinc*)." *U. S.* "It is soluble in less than 3 parts of cold *water*, and in 30 parts of *alcohol* (90 per cent.). Its solution in *water* slightly reddens *litmus*, and is clear, or has only a slight milkiness, which disappears on the addition of *acetic acid*. It affords the reactions characteristic of lead and of acetates. It should yield no characteristic reaction with the tests for silver, copper, arsenium, iron, zinc, calcium, sodium, potassium, ammonium, chlorides, or nitrates. Each gramme dissolved in *water* should require for complete precipitation 53·1 cubic centimetres of the *decinormal volumetric solution of sulphuric acid*." *Br.* Exposed to the air, it effloresces slowly. In pure distilled water, free from carbonic acid, it ought to dissolve entirely and form a clear solution. The commercial acetate is sometimes impure from the presence of lead sulphate and carbonate. In purchasing it the apothecary should select large crystalline masses. Mr. John Mackay analyzed a specimen of this salt, derived from the London market, which contained nearly 30 per cent. of lead sulphate. (*P. J. Tr.*, Jan. 1856, 316.) Sulphuric acid, when added to a solution of lead acetate, produces instantly a precipitate of lead sulphate, and the disengaged acetic acid gives rise to vapors having the smell of vinegar. The salt, when heated, first fuses and parts with its water of crystallization, and afterwards is decomposed, yielding acetic acid and pyroacetic spirit (acetone), and leaving a residue of charcoal and reduced lead. An important property of sugar of lead is its power of dissolving a large quantity of lead monoxide. (See *Liquor Plumbi Subacetatis.*)* It consists of one atom of lead, which has replaced the two hydrogen atoms furnished by two molecules of acetic acid, $C_2H_3O_2.H$, so that its formula becomes $Pb(C_2H_3O_2)_2$, and this in crystallizing takes $3H_2O$. Its molecular weight is therefore 378.

Incompatibles and Tests. Lead acetate is decomposed by all acids, and by those soluble salts the acids of which produce with lead protoxide insoluble or sparingly soluble compounds. Acids of this character are sulphuric, hydrochloric, citric, and tartaric. It is also decomposed by lime water, and by ammonia, potassa, and soda; the last two, if added in excess, dissolving the precipitate at first formed. It is decomposed by hard water, in consequence of the calcium sulphate and common salt which such water usually contains.

Medical Properties and Uses. Lead acetate, in medicinal doses, is a powerful astringent and sedative; in overdoses, an irritant poison, which has in a number of cases caused death. Burning epigastric pain, vomiting of a white curdy matter (lead chloride), and diarrhœa or constipation with black stools (lead sulphide), and finally collapse, are the characteristic symptoms. Its antidote is any soluble sulphate, common salt, soap, or an alkali. In

* *Lead Subacetate* (*Crystallized*). Mr. James Kennedy recommends this salt for preparing the cerate, as follows: Dissolve 4 parts of Lead Acetate in 4 parts of Boiling Distilled Water, add 3 parts of Litharge, boil for fifteen or twenty minutes, stirring, and occasionally adding water to replace that evaporated, allow to stand a few minutes, decant and filter the solution; concentrate by evaporation and allow to crystallize. By dissolving 25 parts of this salt in 75 parts of previously boiled water, *Liquor Plumbi Subacetatis*, corresponding to the official requirements, is obtained. (*Pharm. Rec.*, 1886, p. 50.)

medicinal doses lead acetate is a powerful sedative astringent. It is especially useful in the treatment of *diarrhœas*, and even of *dysentery*, when the discharges are excessive. At one time it was much used for the relief of *internal hemorrhages*, but it has been substituted by more effective remedies. It may be, however, effective in *gastric* or *intestinal hemorrhages*. In many cases of *chronic diarrhœa* or in diarrhœas occurring in exhaustive, uncontrollable disease, such as phthisis, lead acetate, combined with opium, may be a valuable palliative in checking discharges. It has been given also in *aneurism* of the aorta. The prolonged medicinal use of acetate of lead may give rise to subacute or chronic lead-poisoning.

The dose of lead acetate is from one to three grains (0·065–0·20 Gm.), in the form of pill, repeated every two or three hours. It is generally given combined with opium. The solution for external use may be made by dissolving from two to three drachms in a pint of water; and, if it be wanted clear, a fluidrachm of vinegar or of dilute acetic acid may be added, which immediately dissolves the lead carbonate, to which its turbidity is owing. When the skin is denuded of the cuticle, the solution should be weaker. The usual strength of the solution as a collyrium is from one to two grains (0·065 to 0·13 Gm.) to the fluidounce (30 C.c.) of *distilled* water.

PLUMBI CARBONAS. U. S., Br. Lead Carbonate. [White Lead.]

$(PbCO_3)_2.Pb(OH)_2$; 772·82. (PLŬM'BĪ CĂR'BŌ-NĂS.) $Pb(CO_3)_2.Pb(HO)_2$; 773·5.

"Lead Carbonate or hydroxy-carbonate, $2PbCO_3,Pb(OH)_2$, may be prepared by the interaction of lead, water, and carbonic anhydride, in the presence of vapors of acetic acid." *Br.*

Cerussa, *P. G.;* Plumbum Carbonicum, Carbonas Plumbicus, Ceruse; Céruse, Carbonate de Plomb, Blanc de Plomb, Blanc de Céruse, *Fr.;* Bleiweiss, *G.;* Cerussa, *Lat., It.;* Albayalde, *Sp.*

Preparation. Lead carbonate is prepared by two principal methods. By one method it is obtained by passing a stream of carbonic acid through a solution of lead subacetate. The acid combines with the lead hydrate of the basic salt, and precipitates as lead carbonate, while a neutral acetate remains in solution. This, by being boiled with a fresh portion of oxide, is again brought to the state of basic salt, when it is treated with carbonic acid as before. In this way the same portion of acetate repeatedly serves the purpose of being converted into subacetate and of being decomposed by carbonic acid. The carbonate obtained is washed, dried with a gentle heat, and thrown into commerce. This process, which produces white lead of the first quality, was invented by Thénard, about the year 1802, and is that which is usually pursued in France and Sweden, and known as the "Clichy process." A modification of the process of Thénard, known as Benson's, is now used by some manufacturers in England. It consists in mixing litharge with a hundredth part of lead acetate, and subjecting the mixture, previously moistened with very little water, to a stream of carbonic acid.

The other method, which consists in exposing lead to the vapors of vinegar, originated in Holland, whence the name "Dutch process," and is usually pursued in England and the United States,—but in England with some modifications which are not well known. We shall describe this process as employed by our own manufacturers. The lead is cast into thin sheets, made by pouring the melted lead over an oblong sheet-iron shovel, with a flat bottom, and with raised edges on its sides, which is held in a slanting direction over the melting-pot. As many of these sheets are then loosely rolled up as may be sufficient to form a cylinder five or six inches in diameter, and seven or eight high, which is placed in an earthen pot containing about half a pint of vinegar, and having within a few inches from the bottom three equidistant projecting knobs in the earthen-ware, on which the cylinder of lead is supported in order to keep it from contact with the vinegar. The pots thus prepared are placed side by side, in horizontal layers, in a building roughly constructed of boards, with interstices between them. The first layer is covered with boards, on which a stratum of tan or of refuse straw from the stables is strewed; and fresh layers of pots, boards, and tan or straw are successively placed until the building is filled. The sides are also enclosed with straw. The layers of pots contained in one building, called a stack, are allowed to remain undisturbed for about six weeks, at the end of which time they are unpacked, and the cylinder of sheet-lead in each pot, though still retaining its shape, is found almost entirely converted into a flaky, white, friable substance, which is the white lead. This is separated from the lead yet remaining in the metallic state, ground in water, whereby it is washed and reduced to fine powder, and finally dried in long shallow reservoirs, heated by steam. Pelouze has succeeded in explaining these processes on one general principle. In Thénard's process it is admitted that the same portion of lead acetate unites with oxide, and gives it up again to carbonic acid to form the carbonate. In the modified English process,

referred to above, he supposes that the one per cent. of lead acetate combines with sufficient litharge to convert it into subacetate, which immediately returns to the state of neutral acetate by yielding up its excess of base to form the carbonate with the carbonic acid. The acetate is now ready to combine with a fresh portion of litharge, to be transferred to the carbonic acid as before; and thus the small proportion of acetate, by combining with successive portions of the litharge, finally causes the whole of the latter to unite with the carbonic acid. In the Dutch process, Pelouze has rendered it almost certain that none of the oxygen or carbonic acid of the carbonate is derived from the vinegar. In this process he supposes that the heat generated by the fermentation of the tan or straw volatilizes the vinegar, the acetic acid of which, with the assistance of the oxygen of the air, forms with the lead a small portion of subacetate. This, by reacting with the carbonic acid resulting from the decomposition of the tan or straw, or derived from the atmosphere, forms lead carbonate, and is brought to the state of neutral acetate. The neutral acetate returns again to the state of subacetate, and, by alternately combining with and yielding up the oxide, causes the whole of the lead to be finally converted into carbonate.

The temperature of the stacks of pots in the Dutch process is about 45° C. (113° F.). If it falls below 35° C. (95° F.), a part of the lead escapes corrosion, and if it rises above 50° C. (122° F.), the product is yellow. The form of acetic acid usually employed in this process is vinegar; but the variable nature of that liquid as to strength and purity is an objection to its use; and, accordingly, other forms of the acid have been substituted with advantage, as, for example, the purified acetic acid from wood in a diluted state. The German or chamber process differs from the Dutch process only in that the vessels containing the lead are placed in chambers having a perforated floor, through the openings of which the fumes of acetic acid rise, acting upon the lead, while carbon dioxide from the burning of coke is passed in and through the chamber. This process is cheaper than the Dutch method, and is said to give an equally satisfactory product. Another method, which yields a white lead of excellent covering power, is the process patented in England by Dale and Milner. This consists in carefully grinding between millstones a mixture of litharge or any insoluble basic lead salt with water and sodium bicarbonate. Milner has improved upon this method by grinding a mixture of 4 parts of finely divided litharge with 1 part of common salt and 16 parts of water. After about 4½ hours the reaction is complete. The mixture of basic lead chloride and caustic soda is then transferred to a leaden vessel, well stirred with a wooden pestle, and a current of carbon dioxide passed through it until the liquid is neutral. If the carbon dioxide be passed in too long, the product will be spoiled. (*Roscoe and Schorlemmer*, vol. ii., 1, 293.) The production of white lead in the United States reaches large proportions, amounting in 1897 to 103,235 tons, valued at $9,291,150.

Properties. "A heavy, white, opaque powder, or a pulverulent mass, without odor or taste. Permanent in the air. Insoluble in water or alcohol, but soluble in acetic or diluted nitric acid, with effervescence. When strongly heated, the salt turns yellow without charring, and, if heated in contact with charcoal, it is reduced to metallic lead. If 2 Gm. of the salt be dissolved in a mixture of 2 C.c. of nitric acid and 10 C.c. of water, it should not leave more than 0·02 Gm. of residue (limit of *insoluble foreign salts*). This solution yields a black precipitate with hydrogen sulphide test-solution, a yellow one with potassium iodide test-solution, and a white one with diluted sulphuric acid. On completely precipitating the solution with hydrogen sulphide, the filtrate should not leave more than a trifling residue on evaporation (limit of *salts of the alkalies, alkaline earths*, or of *zinc*). If 1 Gm. of the salt be strongly ignited, in a porcelain crucible, it should leave a residue of lead oxide weighing not less than 0·85 Gm." *U. S.* It is sometimes adulterated with barium, calcium, and lead sulphates, particularly the first. A mixture of equal parts of white lead and barium sulphate is known as *Venetian white*, whilst *Hamburg white* is a mixture of 1 part of white lead and 2 parts of barium sulphate, and *Dutch white* of 1 part to 3 of barium sulphate. M. Louyet has examined samples of French white lead containing considerably more than half their weight of barium sulphate. These sulphates, if present, are left undissolved by nitric acid. Chalk or whiting is another adulteration. This may be detected by adding to the nitric solution of the white lead an excess of potassa, which will redissolve the lead monoxide first thrown down, but leave a white powder of lime. The British Pharm. describes it as a soft, heavy powder, insoluble in water, entirely soluble in diluted acetic acid. Neutral lead carbonate consists of one atom of lead, one of carbon, and three of oxygen. Commercial white lead is a compound of lead carbonate and hydrate. Its formula is generally taken as $(PbCO_3)_2 + Pb(OH)_2$. According to

Stein, white lead, when submitted to simple calcination, loses 14·5 per cent. of its weight; and a mode of determining its purity is thus afforded. (*Journ. de Pharm.*, Janv. 1859, 78.) But the fact seems to be, from the observations of Mr. Wm. Baker, that commercial white lead contains variable proportions of the hydrated oxide, from a mere trace to the amount of 1 mol. to 3 mols. of the neutral carbonate. (*Chem. News*, Aug. 10, 1861, 74.)

Medical Properties and Uses. White lead is ranked in the Materia Medica as an astringent and sedative. It is employed externally only, being used, in the form of ointment, as an application to *ulcers* and to *inflamed and excoriated surfaces*. It was recommended in *scalds* and *burns* by the late Prof. Gross; and Mr. Alfred Freer has found it very useful in *erysipelas*, *eczema*, *carbuncle*, etc. (*P. J. Tr.*, Aug. 1859.) The white lead is first brought to the consistence of cream by linseed oil, as in making common white paint, and then brushed over the inflamed surface. Its free continued external use has produced lead-poisoning. (Case, *N. A. Medico-Chir. Rev.*, July, 1857, p. 605.) Although highly insoluble, on account of its frequent use in the arts and of the ease of its formation when lead is exposed to chemical influences, lead carbonate probably produces chronic poisoning more often than any other preparation of the metal. The constant use of face-powders and cosmetics containing lead carbonate, or "*flake white*," as it is sometimes called, has produced serious results.

PLUMBI IODIDUM. U. S., Br. Lead Iodide.

PbI_2; 459·46. (PLŬM′BĪ Ī-ŎD′Ī-DŬM.) PbI_2; 459·7.

"Precipitated Lead Iodide, PbI_2, is obtained by the interaction of lead nitrate or acetate and potassium iodide." *Br.*

Plumbum Iodatum, *P. G.;* Ioduretum Plumbicum; Iodure de Plomb, *Fr.;* Jodblei, *G.*

"Take of Nitrate of Lead, Iodide of Potassium, each, *four ounces* [avoirdupois]; Distilled Water *a sufficiency*. Dissolve the Nitrate of Lead, by the aid of heat, in a pint and a half, and the Iodide of Potassium in half a pint of the Water, and mix the solutions. Collect the precipitate on a filter, wash it with Distilled Water, and dry it in a warm place." *Br.* 1885.

No process is given in the U. S. P. 1890 nor Br. Ph. 1898 for Lead Iodide. The process of the U. S. P. 1870 was identical with that of the British Pharm. 1885 given above.

The lead nitrate gives up its metal to the iodine, receiving the potassium; the operation taking place between one mol. of the lead nitrate and two mols. of the potassium iodide. The potassium nitrate thus formed remains in solution, while the lead iodide is precipitated, $Pb2NO_3 + 2KI = 2KNO_3 + PbI_2$. The theoretical quantities of lead nitrate and potassium iodide are 330·18 of the former and 331·12 of the latter, or almost precisely equal quantities. The proportions should be as nearly as possible those of exact saturation. An excess of the potassium iodide, independently of the waste, has the disadvantage of holding a portion of the lead iodide in solution; while, according to Christison, an excess of lead over the iodine disposes to the formation of the lemon-yellow insoluble lead oxyiodide. By the use of equal quantities of the two salts these disadvantages are avoided. As lead iodide is slightly soluble in cold water, it is desirable to use as little of the solvent as will answer; and hence the comparatively small proportion of water employed.

In the former London process lead acetate was employed instead of the nitrate; but M. Depaire, of Brussels, ascertained that in this process a considerable amount of iodide remains in solution after the precipitation of the lead iodide; and M. F. Boudet states that the quantity of the iodide resulting from the process is 10 per cent. less than theory would indicate. By the addition of nitric acid to the solution, after precipitation, an additional quantity of lead iodide is obtained. M. Boudet ascribes this result to the formation of a portion of soluble potassium and lead iodide, whenever lead iodide and potassium acetate are in contact. By substituting lead nitrate for acetate, he found that a quantity of lead iodide was obtained as near that required by theory as the solubility of the lead iodide permits. (*Journ. de Pharm.*, 3e sér., xi. 274.) The official process is on the whole to be preferred to that in which lead acetate is used, and especially as the nitrate is more easily obtained pure. Some interesting experiments have been made by M. T. Huraut, of Paris, on the different methods of preparing lead iodide. It may be obtained by the reaction between any of the soluble iodides and the soluble lead salts. It resulted from his observations that of the two lead salts employed, the nitrate was to be preferred, and of the various iodides, though potassium iodide yielded a very handsome product, yet calcium iodide afforded one not inferior in quality, and somewhat greater in quantity. Upon a small scale, as the process is performed by the apothecary, the difference would be of little consequence; but it might be important to the manufacturer. (See *A. J. P.*, xxi.)

As obtained by the official process, lead iodide is in the form of "a heavy, bright yellow powder, without odor or taste. Permanent in the air. Soluble in about 2000 parts of water at 15° C. (59° F.), and in about 200 parts of boiling water, separating from the latter solution in brilliant, golden-yellow spangles or crystalline laminæ. Very slightly soluble in alcohol, but soluble, without color, in solutions of the fixed alkalies, in concentrated solutions of the acetates of the alkalies, of potassium iodide, and of sodium hyposulphite, and in a hot solution of ammonium chloride. When moderately heated, the salt fuses to a thick, reddish-brown liquid, which congeals, on cooling, to a yellow, crystalline mass. At a higher temperature it is decomposed, with the evolution of violet vapors of iodine, leaving a lemon-yellow residue of lead oxyiodide. If 1 Gm. of the salt be triturated with 2 Gm. of ammonium chloride and 2 C.c. of water, a nearly white mixture will result. If this be transferred to a test-tube, and heated in a water-bath for a few minutes, a clear and almost colorless solution should be formed (absence of *chromate* and of *other insoluble foreign salts*). On cooling this solution, a solid mass of nearly colorless, fine, silky crystals will be produced, and on adding water or diluted sulphuric acid to this mass, yellow lead iodide will be separated. If 1 Gm. of the salt be boiled for a few minutes with 20 C.c. of water, the mixture then cooled and filtered, the lead removed from the filtrate by hydrogen sulphide, and the new filtrate somewhat concentrated by evaporation, a portion of this liquid, when mixed with a little sulphuric acid, and tinted with a drop of indigo test-solution, should not become decolorized on heating (absence of *nitrate*). If another portion of the liquid be carefully neutralized with ammonia water, it should not become colored red by a drop of ferric chloride test-solution (absence of *acetate*). If the remainder of the filtrate be evaporated to dryness, it should leave no residue (absence of *soluble foreign salts*)." *U. S.* "A heavy bright-yellow powder, soluble in about 2000 parts of cold and in about 200 parts of boiling *water*, and deposited in golden-yellow crystalline scales as the latter solution cools; entirely soluble in *solution of ammonium chloride*. It affords the reactions characteristic of lead and of iodides. It should yield no characteristic reaction with the tests for nitrates or acetates." *Br.* According to Soubeiran, it is soluble in 1235 parts of cold water, and 194 of boiling water, which, on cooling, deposits it in minute, shining, golden-yellow, crystalline scales. It is freely soluble in a concentrated solution of sodium acetate (Donato Tommasi, *P. J. Tr.*, 3d series, ii. 805). It should be kept excluded from the light. It is stated by Engelhardt that iodine is separated from lead iodide by iron and copper perchlorides; while the other metallic chlorides have no such effect, producing compounds of iodides of the metal employed with lead chlorides. (*Chem. Gaz.*, Jan. 15, 1856, p. 24.)

Medical Properties and Uses. This compound is supposed to have the resolvent properties of iodine, combined with those which are peculiar to lead, and was at one time recommended in *tuberculous diseases*, in which, however, it has proved wholly inefficient. It is said to have been usefully employed in the discussion of *scrofulous tumors* and other indolent swellings, and in the cure of obstinate *ulcers*, and for these purposes has been used both internally and locally in the form of an ointment. According to Dr. Cogswell, if given for some time in small doses, it produces the effects of lead, but not those of iodine, upon the system. (*Christison's Dispensatory.*) Dose, from half a grain to four grains (0·03–0·26 Gm.).

PLUMBI NITRAS. U. S. Lead Nitrate.

$Pb(NO_3)_2$; 330·18. (PLŬM'BĪ NĪ'TRĂS.) $Pb(NO_3)_2$; 330·5.

Nitrate of Lead; Plumbum Nitricum, Nitras (Azotas) Plumbicus, *Lat.;* Nitrate de Plomb, *Fr.;* Salpetersaures Bleioxyd, Bleisalpeter, *G.;* Nitrato di Piombo, *It.;* Nitrato de Plomo, *Sp.*

Neither the U. S. nor the Br. Pharmacopœia gives a formula for the preparation of this salt. It may be readily prepared by the process of the old Dublin Pharmacopœia: "Take of Litharge, in fine powder, *five ounces* [avoirdupois]; Pure Nitric Acid *two fluidounces;* Distilled Water *three pints* [Imp. meas.]; Dilute Nitric Acid *a sufficient quantity*. To the Litharge, placed in a porcelain dish, add the Acid with a pint and a half of the Water, and, applying a sand heat, and occasionally stirring the mixture, evaporate the whole to dryness. Upon the residue boil the remainder of the Water, clear the solution by filtration, and, having acidulated it by the addition of a few drops of the Dilute Nitric Acid, evaporate until a pellicle begins to form. The heat being now withdrawn, crystals will form on the cooling of the solution, which should be dried on blotting-paper in a warm atmosphere, and preserved in a close bottle."

Properties. In this process the nitric acid unites directly with the lead oxide to form the nitrate. This nitrate is officially described as in "colorless, transparent, octohedral crystals, when obtained by the spontaneous evaporation of cold solutions, or white, nearly opaque crys-

tals, when formed by the cooling of hot solutions; without odor, and having a sweetish, astringent, afterwards metallic taste. Permanent in the air. Soluble in 2 parts of water at 15° C. (59° F.), and in 0·75 part of boiling water; almost insoluble in alcohol. When strongly heated, the salt decrepitates, emits nitrous vapors, and finally leaves a residue of lead oxide. The aqueous solution has an acid reaction, and yields a black precipitate with hydrogen sulphide test-solution, a yellow one with potassium iodide test-solution, and a white one with diluted sulphuric acid. A 10-per-cent. aqueous solution of the salt should give, with potassium ferrocyanide test-solution, a pure white precipitate (absence of *iron* or *copper*). If hydrochloric acid be added to the aqueous solution until no further precipitate is produced, and the remainder of the lead be removed from the filtrate by hydrogen sulphide, a portion of the new filtrate should not be affected by the addition of a slight excess of ammonia water (absence of *zinc* or *iron*). If another portion be evaporated to dryness, it should leave no residue (absence of *salts of the alkalies*, or of *zinc*)." *U. S.* It is composed of one atom of lead, combined with two nitric acid groups, $(NO_3)_2$, without water of crystallization. This salt is largely used in dyeing and calico-printing, for the preparation of mordants, and of chrome yellow.

Medical Properties. The effects of this salt upon the system are the same as those of the other soluble lead salts; but, though formerly employed, it is now quite out of use as an internal remedy. Externally it is occasionally applied to excoriated surfaces; and a solution made in the proportion of ten grains to an ounce of water, and colored probably with alkanet, has been used on the continent of Europe as a secret remedy in *sore nipples*, *chapped hands*, *cracked lips*, etc., and it undoubtedly, in solutions whose strength should be adapted to the individual case, is a valuable local remedy in diseases of the skin and mucous membranes, such as *leucorrhœa*, *gonorrhœa*, *ulcers*, and *chronic impetiginous affections*. It may be used to correct fetid odors dependent on the presence of hydrogen sulphide or ammonium sulphydrate, which it decomposes; but it is not a germicide or true disinfectant. *Ledoyen's disinfecting fluid* is a solution of lead nitrate in the proportion of a drachm to an ounce. Should the salt be used internally, the dose would be from the fourth to the half of a grain (0·016–0·03 Gm.). Moerlonge and Vanzette ascribe remarkable efficiency to lead nitrate in *onychia maligna*, and their statements have been confirmed by other practitioners. It is applied by sprinkling the powder on the surface, and, according to Dr. J. Scott, of Belfast, Ireland, a complete cure may be relied on in from fourteen to thirty days. (*Dublin Journ. of Med. Sci.*, Feb. 1874, p. 145.)

PLUMBI OXIDUM. U. S., Br. Lead Oxide. [Litharge.]

PbO; 222·36. (PLŬM'BĪ ŎX'Ĭ-DŬM.) PbO; 222·5.

"Lead Oxide, PbO, is prepared by the action of air on melted lead." *Br.*

Oxide of Lead; Lithargyrum, Plumbum Oxydatum, Plumbi Oxidum Semivitreum; Oxide de Plomb fondu, Litharge, Protoxide de Plomb, *Fr.;* Bleiglätte, Bleioxyd, *G.;* Litargirio, *It.;* Almartaga, *Sp.*

When lead oxide is rendered semi-crystalline by incomplete fusion it becomes the *semivitrified oxide*, or litharge. Almost all the litharge of commerce is obtained, as a secondary product, in the process for extracting silver from argentiferous galenas. After extracting the argentiferous lead from the ore, the alloy is placed upon an oval slightly excavated dish, about three feet long and twenty inches wide, called a *test*, made by beating pulverized bone-ash, formed into a paste with water, into a mould, the sides of which consist of an elliptical band of iron, and the bottom of strips of sheet-iron, placed at short distances apart. The test is of such a size as exactly to fit an opening in the floor of a reverberatory furnace, where it is placed and adjusted to the level of the floor. On one side of the test the fireplace is situated, and exactly opposite, the chimney; while at one extremity of it the pipe of a strong bellows is placed, and at the other a vertical hole is made, communicating with a gutter leading from the test. The furnace is now lighted, and shortly afterwards the bellows are put in motion. The lead fuses and combines with oxygen, and the resulting oxide, melting also, forms a stratum which floats on the surface, and which is driven by the blast of the bellows along the gutter and through the vertical hole into a recipient below, where, upon solidifying, it crystallizes in small scales, which form the litharge. In proportion as the lead is oxidized and blown off the test, fresh portions are added so as to keep it always sufficiently full. The process is continued for eight or ten days, after which no more lead is added. The operation is now confined to the metal remaining on the test; and, the oxidation proceeding, a period at last arrives when the whole of the lead has been blown off as litharge, and the silver, known to be pure by its brilliant appearance in the fused state, alone remains. This is then removed, and the process repeated on a fresh portion of argentiferous lead. The yellow amorphous

lead oxide used as a paint color is known as *massicot*, and is prepared by careful heating of lead carbonate or nitrate to a point short of the fusion of the resulting oxide.

Properties. "A heavy, yellowish or reddish-yellow powder, or minute scales, without odor or taste. On exposure to the air it slowly absorbs moisture and carbon dioxide. Almost insoluble in water, to which it, however, imparts a faintly alkaline reaction; insoluble in alcohol; but soluble in acetic or diluted nitric acid, and in warm solutions of the fixed alkalies. When heated, the Oxide assumes a brownish-red color, becoming yellow again on cooling. It fuses at a red heat. When heated in contact with charcoal, it is reduced to metallic lead. Lead Oxide should be soluble in diluted nitric acid with but little effervescence (limit of *carbonate*), and without the development of the odor of *nitrous acid*, leaving not more than a trifling residue (absence of *silicate*, *barium sulphate*, etc.). The solution, which should be colorless, yields with hydrogen sulphide test-solution a black precipitate, with potassium iodide test-solution a yellow one, and with diluted sulphuric acid a white precipitate, the latter being soluble in a strong solution of sodium hydrate. If from the solution in diluted nitric acid the lead be precipitated by sulphuric acid, the filtrate, after the addition of an excess of ammonia water, should not assume more than a slight bluish tint (limit of *copper*), nor yield more than traces of a reddish-yellow precipitate (limit of *iron*). If 5 Gm. of the Oxide contained in a small flask be shaken with 5 C.c. of water, then 20 C.c. of acetic acid added, and the mixture boiled for a few minutes and filtered, the insoluble residue, when well washed and dried, should not weigh more than 0·075 Gm. (absence of more than 1·5 per cent. of *insoluble impurities*). When strongly heated, in a porcelain crucible, the Oxide should not lose more than 2 per cent. of its weight (limit of *carbonate* and of *moisture*)." *U. S.* "Heavy scales of a pale yellowish-red color, completely soluble in *diluted nitric acid* and in *acetic acid*. It gives the reactions of lead, but should yield no characteristic reaction with the tests for copper, iron, or carbonates." *Br.* It slowly attracts carbonic acid from the air, and contains more of this acid the longer it has been exposed. It is on this account that it commonly effervesces slightly with the diluted acids. It has the property of decolorizing wines, when agitated with them. When heated with the fats and oils, in connection with water, it saponifies them. (See *Emplastrum Plumbi.*) Heated with charcoal, it is reduced to the metallic state. In diluted nitric acid it should be almost entirely soluble; and the solution is affected by potassa in the same manner as that of the carbonate. (See *Plumbi Carbonas.*) As it occurs in commerce, it usually contains iron, copper, and a little silver and silica. It may be purified from iron and copper by digestion in diluted sulphuric acid. The English litharge is most esteemed, that from Germany being generally contaminated with iron and copper. In choosing litharge, samples should be selected which are free from copper and from fragments of vegetable matter. Copper is detected if upon adding potassium ferrocyanide to a nitric acid solution of the litharge a brown instead of a white precipitate is produced. Two varieties of litharge are distinguished in commerce, named from their color, and dependent on differences in the process employed. Sometimes it has a pale yellow color and silvery appearance, and is then denominated *silver litharge* or *yellow litharge;* at other times it is of a red color, and is known under the name of *gold litharge* or *red litharge*. The latter was supposed to owe its color to the presence of a portion of red lead; but M. Leblanc has shown that the two varieties of litharge differ in color, structure, and density only, and not in chemical composition. In this respect litharge is essentially identical with lead oxide. (See *Plumbum.*) The carbonic acid which it contains is variable; but its average amount is about 4 per cent. Lead peroxide and red lead in litharge may be detected by heating it in a test-tube with sodium chloride and potassium bisulphate and introducing a slip of paper colored blue by indigo. If either of these oxides be present, the paper will be bleached by the chlorine evolved.

Litharge is never used internally, but is employed in several pharmaceutical operations, and forms an ingredient in various external applications, used for abating inflammation, and for other purposes. In the arts it is employed in the glazing of pottery, in painting to render oils drying, and as an ingredient in flint glass.

PODOPHYLLUM. U. S. (Br.) Podophyllum. [May-Apple.]

(PŎD-Ǫ-PHĬL'LŬM.)

"The rhizome and roots of Podophyllum peltatum, Linné (nat. ord. Berberideæ)." *U. S.*
"The dried rhizome and roots of Podophyllum peltatum, Linn." *Br.*

Podophylli Rhizoma, *Br.;* **Podophyllum Root, Mandrake Root; Rhizome de Podophyllum,** *Fr.;* **Fussblattwurzel,** *G.*

Podophyllum peltatum. L. *Sp. Pl.* (1753) 505; Willd. *Sp. Plant.* ii. 1141; Barton, *Med. Bot.* ii. 9; Carson, *Illust. of Med. Bot.* i. 18, pl. 11; *B. & T.* 17. The may-apple, sometimes also called *mandrake*, is an indigenous herbaceous plant. The rhizome is perennial, creeping, usually several feet in length, about one-quarter of an inch thick, brown externally, smooth, jointed, and furnished with roots at the joints. The stem is about a foot high, erect, round, smooth. The basal leaves are centrally peltate, with six or seven wedge-shaped lobes, irregularly incised at the extremity, yellowish green on their upper surface, paler and slightly pubescent beneath. The flower-bearing stems bear from one to three similar leaves. The flower is nodding, and appears generally between two leaves at the apex of the stem or at the base of the upper leaf when three leaves are present. The calyx is composed of three oval, obtuse, concave, deciduous sepals. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The stamens are from thirteen to twenty, shorter than the petals, with oblong, yellow anthers, of twice the length of the filaments. The stigma is sessile, and rendered irregular on its surface by numerous folds or convolutions. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish fleshy pulp, in which about twelve ovate seeds are embedded. It is, when ripe, of a lemon-yellow color, diversified by round brownish spots.

The plant has been found on Mount Togakushi, in Japan, and is extensively diffused through the United States, growing luxuriantly in moist shady woods and in low marshy grounds. It is propagated by its creeping root, and is often found in large patches. The flowers appear about the end of May and the beginning of June; and the fruit ripens in the latter part of September. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its color and shape, it is sometimes called *wild lemon*. The root is the official portion, and is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying.

The rhizome of the Himalayan species, *Podophyllum emodi*, is an active cathartic, which has been found by Dymock and Hooper to yield 12 per cent. of resin. It was at first believed that the Indian plant would prove more active than the American, but experience has shown that these expectations are fallacious. (*P. J. Tr.*, 1898, 304.)

Properties. The dried root is much wrinkled lengthwise, is yellowish or reddish brown externally, and furnished with fibres of a similar but somewhat paler color. It was determined, by an experiment of Mr. Wm. Saunders, that these fibres contain as much active matter as the rhizome itself. The fracture is short and irregular, and the internal color whitish. The microscopic examination of the section shows the rhizome to be composed of loose parenchymatous tissue, with sixteen or more yellowish vascular bundles arranged in a circle, and a cortical layer of a double row of thick-walled yellowish cells surmounted by the epidermis. It is officially described as "of horizontal growth, consisting of joints about 5 Cm. long, flattish cylindrical, about 5 Mm. thick, but somewhat enlarged at the end, which has a circular scar on the upper side, a tuft of about ten, nearly simple, fragile roots on the lower side, and is sometimes branched laterally; smooth or somewhat wrinkled, orange-brown, internally white and mealy, with a circle of small wood-bundles; pith large; nearly inodorous; taste sweetish, somewhat bitter and acrid." *U. S.* The powder is light yellowish gray, resembling that of jalap. The root in its aggregate state is nearly inodorous, but in powder has a sweetish not unpleasant smell. The taste is at first sweetish, afterwards bitter, nauseous, and slightly acrid. Both the decoction and the tincture are bitter; but alcohol is said to be the best solvent of the active matter. Dr. V. Podwyssotzki, 1882 (*Pharm. Zeitschrift für Russland*, Bd. xx. 777), made a careful examination of the root and the resin, and announced the active principle to be solely a neutral crystalline principle, *picropodophyllin*. This principle is associated with an inactive resin-acid, *picropodophyllic acid*, and the combination of the two he names *podophyllotoxin*. Picropodophyllin is in colorless, silky, extremely delicate needles, very soluble in chloroform, readily soluble in 95 per cent. alcohol, but very slightly in 75 per cent. alcohol. It is soluble in ether, and crystallizes from a warm saturated solution on cooling. It is insoluble in water, turpentine, or benzin. Podophyllotoxin is a bitter, white, resinous powder, soluble in weak alcohol and hot water. It may be precipitated from its alcoholic solution by water in large quantity. (*P. J. Tr.*, 1882, 1011.) Podwyssotzki also obtained *podophylloquercetin*, the coloring principle, which is closely allied to quercetin and is the cause of the varying color of resin of podophyllum. His results have since been corrected and supplemented by R. Kürsten (*A. J. P.*, 1891, 485), who has obtained the several principles in a purer state. The results of Kürsten's investigation are as follows. The podophyllotoxin prepared by Podwyssotzki's method was not constant

in composition, and its melting point varied from 100° to 125° C.; further, the podophyllic acid of that author is composed mainly of a crystallizable, active, but very impure substance.

Podophyllotoxin, $C_{15}H_{14}O_6$, is obtained by extracting the coarsely powdered rhizome with cold, light petroleum, until freed from fat; after drying in the air, the extraction is continued with chloroform, until the liquid comes away almost free from yellow color. As it is not possible to work with alcohol-free chloroform, too prolonged extraction with chloroform would yield a more impure extract. The chloroform extract is distilled and the residue is dried over a not too warm water-bath, partially dissolved in benzene, filtered, and the filtrate allowed to remain from three to eight days, when a brownish-yellow mass of well-formed, thick, strongly refractive prisms is produced, which is purified by washing with a 50 per cent. alcohol, then with ether, recrystallizing first from boiling benzene, and finally from solution in hot 45 per cent. alcohol; the compound is thus obtained in long, well-formed prisms.

Podophyllotoxin, when oxidized in an alkaline solution in the cold by means of potassium permanganate, yielded, besides a little carbonic anhydride and a brown amorphous substance, principally two compounds, the more considerable of which was *podophyllic acid*, obtained as well-formed, colorless crystals from solution in a mixture of benzene and alcohol. The compound is without action on animals. It melts at from 158°–160° C. Its aqueous solution, neutralized with aqueous potash, gives no precipitate with gold, calcium, or barium chlorides; silver nitrate gives a white precipitate, soluble in much water; copper acetate gives a blue precipitate. The copper salt was prepared as beautiful light green prisms and analyzed.

Picropodophyllin results from the action of alkalies on podophyllotoxin; thus, on heating the latter with aqueous ammonia, a well-crystallized product is obtained, which at first was recrystallized from strong alcohol; but this was found to be unnecessary, as the melting point, 227° C., was not affected by it. Picropodophyllin has the same composition as podophyllotoxin, but they differ in melting point and in their action on polarized light,—the former inactive, the latter lævo-rotatory; the former is less soluble in all liquids than the latter; the latter gives Millon's reaction, the former does not. By oxidation and reduction the two compounds yield the same products.

Dunstan and Henry (*Proc. Chem. Soc.*, March, 1898) find that the constituents of the Indian podophyllum (*Podophyllum emodi*) and of the American podophyllum (*Podophyllum peltatum*) are identical. The chief constituent is the *podophyllotoxin* of Podwyssotzki and Kürsten, which is a neutral crystalline substance (melting point, 117° C.) to which is ascribed the formula $C_{15}H_{14}O_6$. It is strongly lævo-rotatory, and acts as a powerful purgative and intestinal irritant. When heated with alkalies, it is converted by hydration into the salt of an unstable gelatinous acid, *podophyllic acid*, $C_{15}H_{16}O_7$, of which several salts were obtained and analyzed. This acid very readily loses water, and furnishes the crystalline *picropodophyllin* of Podwyssotzki and Kürsten, which is isomeric with podophyllotoxin. It passes again into podophyllic acid when warmed with aqueous alkalies. It melts at 227° C., and is optically inactive. Podophyllotoxin and picropodophyllin furnish identical decomposition products; when oxidized with nitric acid, oxalic acid is the principal product; when fused with alkalies, orcinol and acetic acid are produced. Both substances contain two methyl groups and no hydroxyl. It is likely that picropodophyllin is the lactone of podophyllic acid. Picropodophyllin is therapeutically inactive. The yellow coloring matter of podophyllum, called by Podwyssotzki *podophylloquercetin*, is proved by the authors to be identical with quercetin, the yellow coloring matter of quercitron bark. An uncrystallizable resin, *podophylloresin*, was also isolated and found to exert a purgative action.

Dr. Manlius Smith recommended that the resin should be prepared by forming an alcoholic tincture of the root, evaporating the tincture till most of the alcohol is driven off, and throwing the residue into water, by which the resin is precipitated. The concentration should not be carried too far, as otherwise the resin separates in clots, which cannot be easily washed. According to Dr. Smith, the resin, when pure, is white, and purges actively. It has been called *podophyllin* for many years. (*A. J. P.*, xxiv. 306. See *Resina Podophylli.*)

The *leaves of Podophyllum peltatum* were chemically examined by Mr. Thomas J. Husband, Jr., who obtained from them a resinous matter and a portion of the alkaloid berberine, which is found in the root. This resinous matter consisted of two distinct resins, one soluble in ether and alcohol, the other in alcohol, and both in caustic alkalies and chloroform. Mr. Husband states that the resin obtained from the leaves is similar in its chemical relations to podophyllin, but proved when taken internally to be without its purgative properties, eight grains being taken without other effect than slight headache. (*A. J. P.*, 1869, 200.)

B. F. Carter (*A. J. P.*, 1886, p. 449) has since examined the leaves. He finds tannin, uncrystallizable sugar, coloring matter, and 6 per cent. of resin. This latter seems to be of twofold character, ether dissolving the soft resin, while the hard resin remains behind. The resin has a bitter taste and a much milder action than that of the rhizome. Fused with caustic potash a small amount of protocatechuic acid seems to be formed.

Medical Properties and Uses. Podophyllum is a slow but active and certain cathartic, producing copious liquid discharges, often with much griping. It is generally thought by the profession to be an efficient cholagogue, and the experiments of Prof. Rutherford upon dogs certainly confirm this belief. It is very much employed in various parts of the country in *bilious fevers* and *hepatic congestions*, and as a general cathartic. In minute doses, frequently repeated, podophyllum has been thought to diminish the frequency of the pulse and to relieve cough, and for these effects has been given in *hæmoptysis* and *catarrh*, but this employment of it is of doubtful advantage. In over-doses podophyllum acts as an irritant poison: an amount estimated at five grains of the resin caused death in a woman sixty years old (*N. Y. Med. Rec.*, April, 1890): the symptoms were vomiting and purging, followed some hours after their cessation by coma, full soft pulse, slight elevation of temperature, and hæmoglobinuria.

The powdered root is never administered, the official extract very rarely: the official resin is much used, under the improper name of *podophyllin*. Dose as a laxative, from one-eighth to one-quarter grain (0·008–0·017 Gm.); as a purgative, from one-quarter to one-half grain (0·017–0·033 Gm.).

POTASSIUM. Potassium.

K; 39·03. (PŌ-TĂS'SĬ-ŬM.) K; 39.

Potassium, *Fr.;* Kalium, Kalimetall, *G.;* Potassio, *It.;* Potasio, *Sp.*

Potassium is a peculiar metal, forming the radical of potassa, and of a number of other compounds used in medicine. It was discovered in 1807 by Sir H. Davy, who obtained it by decomposing fused potassium hydrate by a voltaic current. It was afterwards procured in larger quantity by Gay-Lussac and Thénard, by bringing the fused alkali in contact with white-hot iron, which attracted the oxygen and set free the metal. The process of Brunner, as modified by Wöhler, consists in decomposing potassium carbonate, mixed with charcoal. The mixture of carbonate and charcoal is obtained by heating cream of tartar to redness in a covered crucible. For an account of some improvements in Brunner's process by MM. Mareska and Donny, see *A. J. P.*, xxv. 70. Castner has also prepared it by the process invented by him for the manufacture of metallic sodium. (See *Sodium.*)

Potassium is solid, softer and more ductile than wax, easily cut with a knife, and of a silver-white color. A newly-cut surface is brilliant; but the metal quickly tarnishes by combining with the oxygen of the air, and assumes the appearance of lead. It possesses a remarkably strong affinity for oxygen, and is capable of taking that element from almost every other substance. On account of this property it must be kept in liquids, such as naphtha, which are devoid of oxygen. On the same account, when exposed with a fresh-cut surface to the air, it becomes luminous through a slow combustion, like phosphorus, in the dark. (*Chem. News*, Feb. 28, 1868, p. 108.) Its sp. gr. is 0·865, melting point 62·5° C. (144·5° F.), atomic weight 39·03, and symbol K. When thrown upon water it floats, takes fire, and burns with a rose-colored flame, combining with oxygen, and generating potassium hydrate which dissolves in the water. It forms numerous combinations, uniting with most of the non-metallic elements, and with several of the metals. It combines in three proportions with oxygen, forming a suboxide (K_4O) and a monoxide (K_2O) of a gray color, and a tetroxide (K_2O_4) of a yellowish-brown color. It also unites with chlorine, and forms official compounds with iodine, bromine, cyanogen, ferrocyanogen, and sulphur, under the names of potassium iodide, bromide, cyanide, and ferrocyanide, and sulphurated potassa. Its monoxide is a strong salifiable base existing in nature always in combination, and forming with acids a numerous and important class of salts.

POTASSA. U. S. (Br.) Potassa. [Potassium Hydrate. Potassium Hydroxide. Caustic Potash.]

KOH; 55·99. (PŌ-TĂS'SĄ.) KHO; 56.

"Potassa should be kept in well-stoppered bottles made of hard glass." *U. S.* "Potassium hydroxide, KOH, with not more than 10 per cent. of combined water and impurities, prepared by the interaction of potassium carbonate and calcium hydroxide." *Br.*

Potassa Caustica, *Br.;* Kali Purum; Caustic Potassa, Hydrate of Potassa, Potassium Hydrate; Kali Causticum Fusum, *P. G.;* Potassæ (Potassii) Hydras, Kali Hydricum Fusum, Oxydum Potassicum, Lapis Causticus Chirurgorum; Caustic Potash; Potasse caustique, *Fr.;* Kalium-Hydrat, Kaustisches Kali, *G.*

"Take of Solution of Potash *two pints* [Imperial measure]. Boil down the Solution of Potash rapidly in a [clean] silver vessel, until there remains a [clear] fluid of oily consistence, a drop of which when removed on a warm glass rod solidifies on cooling. Pour this into proper moulds, and when it has solidified, and while it is still warm, put it into stoppered bottles." *Br.* 1885. A process for Potassa is no longer in the U. S. Pharmacopœia: that of 1870 is identical with the British (1885).

The solid alkali obtained from these processes is potassium hydrate, sufficiently pure for medicinal purposes. The solution of the alkali freed from carbonic acid having been obtained by another formula (see *Liquor Potassæ*), the formation of the present preparation requires merely the evaporation of this solution until the whole of its uncombined water is driven off. The evaporation must be performed in metallic vessels, as those of glass or earthen-ware are acted on by the alkali; and it should be completed as quickly as possible, in order to abridge the period during which the solution would be liable to absorb carbonic acid from the atmosphere. When poured out on a metallic plate or dish, the cake, just as it solidifies, may be marked with a knife in the directions in which it is to be divided, and when cold it readily breaks in those directions. A better plan, however, is to run the fused alkali into suitable moulds, as directed in the former U. S. and British formulas. These should be made of silver or iron and have a cylindrical shape, which is the most convenient form of the alkali for surgical use. Green glass bottles with ground stoppers are best adapted for preserving this preparation, as white flint glass is attacked by the alkali.

Properties. It is officially described as in "dry, white, translucent pencils, or fused masses, hard and brittle, showing a crystalline fracture; odorless, or having a faint odor of lye, and of a very acrid and caustic taste. Great caution is necessary in tasting and handling it, as it rapidly destroys organic tissues. Exposed to the air, it rapidly absorbs carbon dioxide and moisture, and deliquesces. Soluble, at 15° C. (59° F.), in about 0·5 part of water, and in 2 parts of alcohol; very soluble in boiling water, and in boiling alcohol; slightly soluble in ether. When heated to about 530° C. (986° F.), Potassa melts to a clear, oily liquid, and at a bright red heat it is volatilized unchanged. When introduced into a non-luminous flame, it imparts to it a violet color. A solution of Potassa, even when greatly diluted, gives an intensely alkaline reaction with litmus paper. The aqueous solution (1 in 20) should be perfectly clear and colorless (absence of *organic matter*). After acidulation with hydrochloric acid it yields bright yellow precipitates with platinic chloride test-solution, and with sodium cobaltic nitrite test-solution. A concentrated, aqueous solution (1 in 10), when dropped into tartaric acid test-solution, produces a white, crystalline precipitate, which redissolves when the Potassa is added in excess. If 1 Gm. of Potassa be dissolved in 10 C.c. of water, and slightly supersaturated with acetic acid, 10 C.c. of the solution should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *lead*, etc.), nor by the subsequent addition of ammonia water in slight excess (absence of *iron*, *aluminum*, etc.). The remainder of the acidulated solution should not be rendered turbid by ammonium oxalate test-solution (absence of *calcium*). If a solution of 1·5 Gm. of Potassa in 10 C.c. of water be slightly supersaturated with nitric acid, then 0·5 C.c. of silver nitrate decinormal volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the addition of more silver nitrate volumetric solution (limit of *chloride*). If to a solution of 3·5 Gm. of Potassa in 10 C.c. of water, strongly supersaturated with hydrochloric acid, 0·1 C.c. of barium chloride test-solution be added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate*). If 1 Gm. of Potassa be dissolved in 2 C.c. of water, and added to 10 C.c. of alcohol, not more than a slight, colorless precipitate should occur within ten minutes (limit of *silicate*). After boiling this alcoholic solution with 5 C.c. of calcium hydrate test-solution and filtering, not the slightest effervescence should take place on adding the filtrate to an excess of diluted hydrochloric acid (limit of *carbonate*). If 0·2 Gm. of Potassa be dissolved in 2 C.c. of water, and carefully mixed with 4 C.c. of pure sulphuric acid and 2 drops of indigo test-solution, the blue color should not be discharged (limit of *nitrate*). To test for *soda*, dissolve 0·56 Gm. of Potassa in 5 C.c. of water, add a few drops of phenolphtalein test-solution, and then, from a burette, enough tartaric acid test-solution (3 Gm. in 20 C.c.) to accurately neutralize the solution. Next add another volume of the tartaric acid test-solution equal to that first used, and then enough absolute alcohol to completely precipitate the potassium bitartrate formed. Separate the precipitate by filtration and wash it with a little alcohol. The filtrate should not require more than 0·2 C.c. of potassium hydrate normal volu-

metric solution to restore the red color (absence of more than 1·5 per cent. of *soda*). To neutralize 0·56 Gm. of Potassa should require not less than 9 C.c. of normal sulphuric acid (each C.c. corresponding to 10 per cent. of pure potassium hydrate), phenolphtalein being used as indicator." *U. S.* "White pencils or cakes, very deliquescent, powerfully alkaline and corrosive. Soluble in half its weight of *water*, and in twice its weight of *alcohol* (90 per cent.). It affords the reactions characteristic of potassium. Each gramme dissolved in *water* or in *alcohol* (90 per cent.) should leave only a trace of sediment, and should require for neutralization at least 16·1 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, copper, or arsenium." *Br.* It is important that the requirements of the Pharmacopœia be complied with, and that potassium hydrate should not contain more than 10 per cent. of impurity. The *white stick caustic potassa* of commerce usually contains from 15 to 28 per cent. of water, which seems to be a necessary impurity, for if a certain quantity of water is not present it is impossible to mould the stick. By heating this so as to drive off the water a purified hydrate in cakes may be obtained. On account of its deliquescent property, and its strong attraction for carbonic acid, caustic potassa requires to be kept in very accurately stopped bottles. As formerly obtained, from solution of potassa derived from an impure carbonate, it contained various impurities, which, however, did not interfere with its medicinal value,—such as potassium chloride and tetroxide, ferric oxide, lime, silica, alumina, potassium sulphate, and a portion of the alkali still in a carbonated state. Official potassa may be rendered nearly pure by digestion in alcohol, which takes up only the alkaline hydrate, evaporating the solution to dryness, and fusing the dry mass obtained. *Potassium hydrate*, when thus procured, is called *potash by alcohol*. It is generally in flat white pieces, which are dry, hard, brittle, and extremely caustic. Its other properties are similar to those of the impure hydrate above described. According to Mr. H. Wurtz, of New York, commercial potash by alcohol usually contains a trace of potassium silicate, which appears to be taken up by the alcohol. The source of this is the potassium carbonate employed, which may be freed from this impurity by evaporating its aqueous solution, in a sheet-iron dish, to dryness, and adding, from time to time, lumps of ammonium carbonate. The silicate is thus converted into the carbonate; and on dissolving the residue the silica appears in flakes, which may be separated by filtration. Potassa may be distinguished from the other fixed alkalies (soda and lithia) by its affording, when in solution, a crystalline precipitate (cream of tartar) with an excess of tartaric acid, and a yellow one with platinic chloride.* Potassa imparts to the flame of burning alcohol in which it is dissolved a reddish tint; soda colors it yellow even in the presence of potassa; and thus a method is afforded of detecting an admixture of the latter with the former alkali. According to Bunsen, when the flame is viewed through a glass having a cobalt-blue color, only the color imparted by potassa is seen, the yellow color of the sodium flame being absorbed by the blue glass. (*Journ. de Pharm.*, Oct. 1860, p. 319.) Potassa is known chemically as potassium hydrate, KOH, and is composed of one atom of potassium, united with one hydroxyl group, OH.

Medical Properties and Uses. This is the old *causticum commune acerrimum*, or *strongest common caustic*. It is a powerful escharotic, quickly destroying the life of the part with which it comes in contact, and extending its action to a considerable depth beneath the surface. In this latter respect it differs from silver nitrate, or lunar caustic, to which it is, therefore, preferred in forming issues and opening abscesses. The most convenient mode of employing the caustic for the formation of an issue is to apply to the skin a piece of linen spread with adhesive plaster, having a circular opening in its centre corresponding with the intended size of the issue, and then to rub upon the skin, within the opening, a piece of the caustic previously moistened at one end.† The application is to be continued till the life of the part is destroyed, when the caustic should be carefully washed off with a wet sponge or wet tow, or neutralized by vinegar. In forming from it solutions of potassa of definite strength, whether for medicinal or for pharmaceutical use, an allowance should be made for the percentage of water it always contains. (See *Liquor Potassæ*.)

* For a method of analyzing commercial potash so as to determine the percentage and character of impurities, see *A. J. P.*, xlvii. 464.

† At the suggestion of Dr. Maunoury, of Chartres, M. E. Robiquet has prepared a paste consisting of gutta-percha and caustic potassa, which offers many advantages of manipulation, in the application of the latter substance. It is prepared by simply melting together equal weights of the two substances. The resulting paste can be moulded into any form that may be thought desirable, either of cylinders, plates, or lozenges, and retains its form indefinitely, even when introduced into cavities. All that is necessary, before applying it, is to dip it into alcohol for a few seconds. The resulting eschars are very precise in their form. (*Journ. de Pharm.*, xxx. 275.)

POTASSA CUM CALCE. U. S. Potassa with Lime.

(PŌ-TĂS'SĄ CŬM CĂL'CĒ.)

Pulvis Causticus cum Calce, Pulvis Causticus Viennensis; Vienna Caustic, Vienna Paste; Caustique (Poudre) de Vienne, *Fr.;* Wiener Aetzpulver, *G.*

"Potassa, *five hundred grammes* [or 17 ounces av., 279 grains]; Lime, *five hundred grammes* [or 17 ounces av., 279 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Rub them together, in a warm iron mortar, so as to form a powder, and keep it in a well-stoppered bottle." *U. S.*

This preparation is "a grayish-white powder, deliquescent, having a strongly alkaline reaction, and responding to the tests for calcium and potassium. It should be soluble in diluted hydrochloric acid without leaving more than a small residue." *U. S.* It should not effervesce on the addition of an acid. It is prepared for use by being made up into a paste with a little alcohol. The paste is applied for ten or fifteen minutes to the part to be cauterized, and is conveniently limited in its operation by a piece of adhesive plaster, in the manner explained under potassa. The former Edinburgh preparation, made by evaporating the solution of potassa to one-third, and adding lime enough to bring it to the state of a firm paste, was often called *causticum commune mitius*, or *milder common caustic.* Potassa with lime is a more manageable caustic than the official potassa, on account of the presence of the lime, which renders it milder, slower in its operation, and less deliquescent, and causes it to spread less beyond the part intended to be affected. Dr. Filhos has improved this caustic by forming it into sticks. To prepare it thus, the potassa is perfectly fused in an iron spoon, and one-third of its weight of quicklime is added in divided portions, the whole being stirred with an iron rod. The fused mass is then run into lead tubes, closed at one end, about three inches long, and from a quarter to half an inch in diameter in the clear. The sticks are kept, still enclosed in the lead tubes with the open end downward, in thick glass tubes, containing some powdered quicklime, and closed with a cork, between which and the stick some cotton is put to steady the caustic. When employed, as much of the caustic is uncovered at the end, by scraping off the lead, as it is proposed to use. This form of caustic is particularly recommended for cauterizing the neck of the uterus. M. E. Robiquet has modified the caustic, by fusing the potassa and lime at a higher heat, running the fused mass into iron moulds, and quickly coating the sticks, when cold, with melted gutta-percha. The higher heat employed renders the caustic harder and more homogeneous.*

POTASSA SULPHURATA. U. S., Br. Sulphurated Potassa. [Liver of Sulphur.]

(PŌ-TĂS'SĄ SŬL-PHŪ-RĀ'TĄ.)

"A mixture of salts of potassium, of which the chief are potassium sulphides." *Br.*

Hepar Sulphuris; Potassii Sulphuretum, *U. S.* 1870; Sulphuret of Potassium, Sulphurated Potash; Kalium Sulfuratum, *P. G.;* Sulfure de Potasse, Foie de Soufre, *Fr.;* Kalischwefelleber, *G.*

"Sublimed Sulphur, *one hundred grammes* [or 3 ounces av., 231 grains]; Potassium Carbonate, dried, *two hundred grammes* [or 7 ounces av., 24 grains]. Mix the powdered and dried Potassium Carbonate thoroughly with the Sublimed Sulphur, and gradually heat the mixture, in a covered crucible, which should be only about half filled with it, until the mass ceases to foam and is in a state of perfect fusion. Then pour the fused mass on a cold marble slab, and, after it has cooled, break it into pieces, and keep it in a well-stoppered bottle." *U. S.*

"Potassium Carbonate, in powder, 10 *ounces* (Imperial) or 100 grammes; Sublimed Sulphur, 5 *ounces* (Imp.) or 50 grammes. Mix the Potassium Carbonate, previously dried, and the Sulphur, in a warm mortar; introduce them into a crucible; heat this, at first gradually, until effervescence has ceased, and finally to dull redness, so as to produce perfect fusion; pour out the liquid contents of the crucible on a clean flagstone, and cover quickly with an inverted porcelain basin so as to prevent free access of air while solidification is taking place. The solid product thus obtained should, when cool, be broken into fragments, and immediately enclosed in a green glass bottle furnished with an air-tight stopper." *Br.*

These processes are essentially the same, except that a greater heat is used in the British process, which somewhat modifies the result. When potassium carbonate is melted with half its weight of sulphur, as in the U. S. process, the carbonic acid is expelled. The composition

* M. Piédagnel states that by mixing the Vienna powder with morphine hydrochlorate, in the proportion of three parts of the former to one of the latter, a caustic is obtained which will produce an eschar without causing pain. He first mixes them intimately in the dry state, and then with alcohol, chloroform, or water, making a paste, which may be applied by means of adhesive plaster. (*Journ. de Pharm.*, 3e sér., xxxiii. 469.)

varies with the heat employed. If the heat does not exceed 185° C. (365° F.), the resulting preparation will contain potassium hyposulphite; if above 300° C. (572° F.), potassium sulphate. (*Fordos and Gélis.*) The reaction for the preparation at the lower temperature is $3K_2CO_3 + (S_2)_4 = 2K_2S_3 + K_2S_2O_3 + 3CO_2$, which at the higher temperature is changed as follows: $4K_2S_2O_3 = 3K_2SO_4 + K_2S_5$. The potassium pentasulphide formed is decomposed at this high temperature into sulphur, which burns off, and K_2S_3. The U. S. preparation, therefore, which is made at the temperature of fusion, probably contains potassium hyposulphite, and may be represented by the formula $2K_2S_3 + K_2S_2O_3$; three mols. of CO_2 escaping; while the British, being prepared at a red heat, contains potassium sulphate, the reaction probably being $4K_2CO_3 + (S_2)_5 = K_2SO_4 + 3K_2S_3 + 4CO_2$.

Potassium carbonate from pearlash is usually employed by the manufacturer; but in the process of M. Henry, which is stated to be the best yet devised, the pure potassium carbonate is employed. His formula is as follows. Mix two parts of pure potassium carbonate with one of sulphur reduced to powder, and put the mixture into flat-bottomed matrasses, which should be only two-thirds filled. These are placed on a sand-bath, and the fire is applied so as, at first, to produce only a gentle heat, which is afterwards increased. Care must be taken that the necks of the matrasses do not become obstructed. The heat is continued until the matter is brought to a state of tranquil fusion, when it is allowed to cool. The mass obtained, which is compact, smooth, and of a fine yellow color, is broken into pieces, and preserved in well-stopped bottles. W. Elborne (*Yearbook of Pharmacy*, 1896, 331) states that when commercial potassium carbonate is used in making sulphurated potassa, a product is obtained which more closely approaches the official compound (Br. Ph. 1885) than does one made from a pure potassium carbonate. He recommends that dried commercial carbonate containing not less than 90 per cent. K_2CO_3 be employed.

Properties. Sulphurated potassa, when properly prepared, is a hard, brittle substance, having a nauseous, alkaline, and bitter taste. Its color is liver-brown, and hence its name of *hepar sulphuris*, or *liver of sulphur*. The color of the surface of a fresh fracture is brownish yellow. It is inodorous when dry, but emits a slightly fetid smell when moist, owing to the extrication of a little hydrogen sulphide gas. It is soluble in water, forming an orange-yellow liquid, and exhaling the smell of hydrogen sulphide. It is officially described as follows. "When freshly prepared, Sulphurated Potassa forms irregular pieces of a liver-brown color, which, by exposure to the air, gradually absorb moisture, oxygen, and carbon dioxide, and change to a greenish-yellow and finally to a gray mass containing potassium carbonate, hyposulphite, and sulphate. The compound has a faint odor of hydrogen sulphide, and a bitter, alkaline taste. Soluble in 2 parts of water at 15° C. (59° F.), with the exception of a small residue. Alcohol dissolves only the potassium sulphide, leaving the other constituents (hyposulphite and sulphate) undissolved. The aqueous solution (1 in 10) is of an orange-yellow color, is strongly alkaline to litmus paper, and gives off the odor of hydrogen sulphide. On adding to it acetic acid in slight excess, an abundance of hydrogen sulphide is evolved, while sulphur is precipitated. In this liquid, after filtration, sodium bitartrate test-solution produces an abundant, white, crystalline precipitate. On triturating 1 Gm. of Sulphurated Potassa with 1 Gm. of crystallized copper sulphate and 10 C.c. of water, and filtering, the filtrate should remain unaffected by hydrogen sulphide test-solution, corresponding to at least 12·85 per cent. of sulphur combined with potassium to form sulphide." *U. S.* "Solid greenish fragments, liver-brown when recently broken, alkaline and acrid to the taste, readily forming with *water* a yellow solution which has the odor of *hydrogen sulphide*, and evolves it freely when excess of *hydrochloric acid* is dropped into it, sulphur being at the same time deposited. This acid liquid when boiled and filtered gives a yellow precipitate with *solution of platinum chloride*, and a white precipitate with *solution of barium chloride*." *Br.* By exposure to the air it attracts oxygen, and the potassium sulphide is gradually changed into potassium sulphate, when the preparation becomes inodorous, and white on the surface. The solution is decomposed by the mineral acids, which extricate hydrogen sulphide and precipitate the excess of sulphur. It is also incompatible with solutions of most of the metals, which are precipitated as sulphides. When boiled with an excess of hydrochloric acid and filtered, it gives a yellow precipitate with platinic chloride, and a white one with barium chloride. The preparation of the Br. Pharmacopœia yields about one-half of its weight to alcohol (90 per cent.),—the portion dissolved being potassium sulphide, and the undissolved portion potassium sulphate.

Medical Properties and Uses. Sulphurated potassa is a local irritant, and, in small and repeated doses, is said to increase the frequency of the pulse, heat of the skin, and different

secretions, especially the mucous. Occasionally it vomits and purges. It acts, moreover, as an antacid, and produces the alterative effects of sulphur. By some it is maintained to be sedative, and directly to reduce the action of the heart. It probably does so, when taken in considerable quantities, by the development of hydrogen sulphide. In overdoses it acts, according to Orfila, as a violent poison, corroding the stomach, and depressing the powers of the nervous system. Lead acetate or zinc acetate may be used as an antidote; but the latter is preferable, as less likely to act injuriously in an overdose, and having, besides, emetic properties. The complaints in which it has been most advantageously employed are *chronic rheumatism* and *gout*, and various *cutaneous affections*. It has been given also in *painter's colic*, *asthma*, and *chronic catarrh*, and acquired a short-lived reputation as a remedy in *croup*, after the publication of the essay to which the prize offered by Napoleon for the best dissertation on that disease was awarded. In consequence of forming insoluble sulphides with the metallic salts, it has been proposed as an antidote for some mineral poisons; but Orfila has shown that it does not prevent their effects. Dissolved in water, it has proved efficacious as an external application in *cutaneous diseases*, and in *scabies* is an almost certain remedy. It may be used for this purpose in the form of lotion, bath, or ointment. For a lotion it may be dissolved in water in the proportion of from fifteen to thirty grains to the fluidounce (1–1·95 Gm. to 30 C.c.), and for a bath the same quantity or rather more may be added to a gallon of water. A very small proportion of hydrochloric or sulphuric acid may in either case be added to the solution. The ointment is made by mixing half a drachm of the sulphide with an ounce of lard. The odor is very favorably modified, whether in solution or in the state of ointment, by incorporating with it a little oil of anise. The dose of potassium sulphide is from two to ten grains (0·13–0·65 Gm.), repeated several times a day, and given in pill with liquorice, or in solution with syrup. In *infantile croup*, from one to four grains (0·065–0·26 Gm.) were given every three or four hours.

POTASSII ACETAS. U. S., Br. Potassium Acetate.

$KC_2H_3O_2$; 97·89. (PŌ-TĂS'SĬ-Ī Ą-CĒ'TĂS.) $KC_2H_3O_2$; 98.

"Potassium Acetate should be kept in well-stoppered bottles." *U. S.* "Potassium Acetate, $CH_3.COOK$, is prepared by fusing the product of the interaction of acetic acid and potassium carbonate." *Br.*

Acetate of Potassium: Kali Aceticum, *P. G.;* Sal Diureticum, Acetas Potassicus, s. Kalicus, Terra Foliata Tartari; Acetate of Potash (Potassa), Diuretic Salt; Acétate de Potasse, *Fr.;* Essigsaures Kali, *G.*

The substitution in the U. S. Pharmacopœia of 1870* of potassium bicarbonate for the carbonate used in the British formula was an improvement, as it insured a purer product. The form of acid for generating the salt is official acetic acid, and a colorless solution is obtained. This is evaporated to dryness, but the Br. Pharm. 1885 directed the dry salt to be melted, so that it could be obtained as a solid mass on cooling. When fusion is resorted to, great care must be taken not to use too high a heat, as otherwise part of the acetic acid will be decomposed, and the resulting salt will be discolored. For drying the potassium acetate, Dr. Christison considers the heat of a vapor-bath too low, and that of a sand-bath apt to become too high. He therefore recommends the use of a bath of calcium chloride when operating on a small scale. In conducting the evaporation, it is best to have the solution always slightly acid; for if the alkali predominate, it will react upon the acetic acid when the solution is concentrated, and give rise to discoloration. On account of the liability to discoloration, great care must be observed to avoid the contamination of iron. Some manufacturers use silver dishes.

Potassium acetate may also be obtained by double decomposition between lead acetate and potassium sulphate. When thus procured, it is very white and pure, but liable to the objection, for medical use, that it may possibly contain a little lead. Another method by double decomposition is between calcium acetate and potassium sulphate.

Properties. It is officially described as "a white powder, or crystalline masses of a satiny lustre, odorless, and having a warming, saline taste. Very deliquescent on exposure to the air. Soluble, at 15° C. (59° F.), in 0·36 part of water, and in 1·9 parts of alcohol; with increasing temperature it becomes much more soluble in both liquids. When heated to 292° C. (557·6° F.), the salt fuses. At a higher temperature it decomposes, blackens, and evolves vapors having an empyreumatic odor (an alliaceous odor would indicate the presence of *arsenic*), and finally leaves a white residue of potassium carbonate, which should be completely soluble in water. The

* "Take of Acetic Acid *a pint;* Bicarbonate of Potassium *a sufficient quantity.* Add the Bicarbonate gradually to the Acid until it is neutralized; then filter the solution, and evaporate cautiously, by means of a sand-bath, until a dry salt remains." *U. S.* 1870.

aqueous solution (1 in 20) colors litmus paper blue, but does not redden phenolphtalein test-solution. Upon the addition of sodium cobaltic nitrite test-solution, a copious yellow precipitate is formed. The addition of sodium bitartrate test-solution to the aqueous solution causes a white, crystalline precipitate. When the salt is heated with a small amount of sulphuric acid, vapors of acetic acid are evolved. The addition of a little ferric chloride test-solution to a solution of the salt produces a deep red color, and, upon the application of heat, a pale brown, flocculent precipitate of basic ferric acetate separates." *U. S.* "Either in white foliaceous satiny masses, or in granular particles, very deliquescent, alkaline to *litmus*, soluble in half its weight of *water*, and in 2 parts of *alcohol* (90 per cent.)." *Br.* When unskilfully prepared, it is apt to be more or less colored. Its state of aggregation differs according to the manner in which it is procured. As obtained by evaporating the solution to dryness, agreeably to the directions of the U. S. Pharmacopœia of 1870, it is in the form of soft fibrous masses. As usually prepared and found in commerce, it has a foliated texture, which is given to it by fusion and cooling. On account of this appearance, it was formerly called *foliated earth of tartar*. It must always be preserved in well-stopped bottles.

Tests. The most usual impurities contained in it are silica, potassium sulphate, tartrate, and chloride, and the lead and copper salts. "Having prepared a solution of 2·5 Gm. of the salt in 50 C.c. of water, use 10 C.c. of it for each of the following tests: After a portion has been acidulated with a few drops of hydrochloric acid, the addition of an equal volume of hydrogen sulphide test-solution should produce no precipitate (absence of *arsenic*, *lead*, etc.). In another portion, acidulated with hydrochloric acid, 1 C.c. of barium chloride test-solution should produce no visible change (absence of *sulphate*). If to a portion of the solution, acidulated with nitric acid, 0·1 C.c of silver nitrate decinormal volumetric solution be added, the liquid should, after filtration, show no further change on the addition of more silver nitrate volumetric solution (limit of *chloride*). The addition of 0·3 C.c. of potassium ferrocyanide test-solution should effect no change in the solution within fifteen minutes (limit of *iron*). No coloration or precipitate should be produced by adding 1 C.c. of ammonium sulphide test-solution (absence of *iron*, *aluminum*, etc.). Fragments of the salt, sprinkled upon sulphuric acid, should produce no effervescence (absence of *carbonate*), nor impart any color (absence of *readily carbonizable*, *organic impurities*). If 1 Gm. of Potassium Acetate be, by thorough ignition, converted into carbonate, the residue should require, for complete neutralization, not less than 10 C.c. of normal sulphuric acid (corresponding to at least 98 per cent. of pure Potassium Acetate), methyl-orange being used as indicator." *U. S.* Since the introduction of the cheap method of obtaining pure acetic acid from wood, this salt has scarcely been subjected to adulteration. Potassium acetate is incompatible with the mineral acids, which expel the acetic acid; with sodium and magnesium sulphates; with corrosive sublimate and silver nitrate; and with several other earthy and metallic salts. This salt exists in the juices of many plants, and especially in the sap of trees, and is the principal source of the potassium carbonate existing in the ashes of wood. It consists of one atom of potassium combined with one acetic acid group, $C_2H_3O_2$.

Medical Properties and Uses. In doses of from a scruple to a drachm (1·3–3·9 Gm.) potassium acetate acts as a diuretic, and as a mild cathartic when given to the extent of three or four drachms (11·65–15·5 Gm.). It is employed in *dropsies*, but is not so useful as the bitartrate. Dr. J. A. Easton, of Glasgow, has found it useful in several skin diseases, such as *psoriasis*, *eczema*, and *lepra*, in doses of half a drachm (1·95 Gm.) three times a day. The alkaline treatment of *acute rheumatism* which originated with Dr. Golding Bird is very well carried out by this salt, half an ounce to an ounce (15·5–31·1 Gm.), in dilute solution, being given during the twenty-four hours. Potassium acetate, like the other alkaline salts containing a vegetable acid, may be given in the uric acid diathesis, to render the urine alkaline; for the experiments of Wöhler and others have shown that the acid of these salts undergoes decomposition in the system, leaving the alkali free to act as a carbonate. Vegetable potassium salts increase the oxidation of tissue, and may therefore be very useful as depuratives.

POTASSII BICARBONAS. U. S., Br. Potassium Bicarbonate.

$KHCO_3$; 99·88. (PŌ-TĂS'SĬ-Ī BĪ-CĂR'BŌ-NĂS.) $KHCO_3$; 100.

"Potassium Bicarbonate, $KHCO_3$, may be obtained by saturating a strong aqueous solution of potassium carbonate with carbonic anhydride." *Br.*

Potassium Hydrogen Carbonate; Acid Carbonate of Potassium; Kali Bicarbonicum, *P. G.*; Bicarbonas Potassicus, s. Kalicus; Bicarbonate of Potash; Bicarbonate de Potasse, *Fr.*; Doppelt-Kohlensaures Kali, *G.*

The process of the U. S. P. 1870,* and also that of the British Pharmacopœia, for this salt were abandoned at former revisions.

Mr. Brande gives the following proportions for the preparation of potassium bicarbonate: "100 lbs. of purified potassium carbonate are dissolved in 17 gallons of water [Imperial measure], which, when saturated with carbonic acid, yield from 35 to 40 lbs. of crystallized bicarbonate; 50 lbs. of potassium carbonate are then added to the mother-liquor, with a sufficient quantity of water to make up 17 gallons, and the operation repeated." Wöhler states that charcoal, when mixed with the carbonate, facilitates by its porosity, in a remarkable degree, the formation of the bicarbonate. Thus, he found that, when crude tartar was charred in a covered crucible, and the carbonaceous mass, after having been slightly moistened with water, was subjected to a stream of carbonic acid, the gas was absorbed with great rapidity, and heated the mass so considerably as to render it necessary to surround the vessel with cold water, to prevent the decomposition of the bicarbonate formed. When the temperature diminished, the saturation was known to be completed. The mass was lixiviated in the smallest quantity of water at the temperature of from 29·4° to 37·7° C. (85° to 100° F.), and the solution, after filtration and cooling, deposited the greater part of the bicarbonate in fine crystals. (See *A. J. P.*, x. 82.)

M. Behrens has proposed to obtain potassium bicarbonate by partially saturating the carbonate, dissolved in an equal weight of water, with acetic acid gradually added. Up to a certain point, no carbonic acid is extricated, and a precipitate takes place of pure potassium bicarbonate, equal to half the weight of the carbonate employed. After the bicarbonate is separated, the saturation may be completed, and potassium acetate obtained. (*Journ. de Pharm.*, 3e sér., iv. 464.) L. Pesci dissolves purified caustic potassa in 80-per-cent. alcohol, and passes a stream of carbonic acid through the solution until it is saturated. The white precipitate is collected and washed with alcohol; it is free from chlorides and nitrates. (*Ber. d. Chem. Ges.*, 1876.)

According to Berzelius, the cheapest method of obtaining potassium bicarbonate is to suspend a concentrated solution of the purified carbonate, contained in a stone-ware dish, within a cask, over a liquid undergoing the vinous fermentation. The alkali is thus surrounded by an atmosphere of carbonic acid, and, by absorbing it, crystallizes into bicarbonate in the course of five or six weeks. Distillers and brewers may prepare this salt with great facility by suspending the alkaline solution in the fermenting tun. The salt in powder called *potash sal aëratus*, made principally in New England, is prepared in this way. In composition it is between a carbonate and a bicarbonate.

Properties. Potassium bicarbonate is officially described as in "colorless, transparent, monoclinic prisms, odorless, and having a saline and slightly alkaline taste. Permanent in the air. Soluble in 3·2 parts of water at 15° C. (59° F.), and in 1·9 parts at 50° C. (122° F.). At a higher temperature the solution rapidly loses carbon dioxide, and, after being boiled, contains only potassium carbonate. Almost insoluble in alcohol. The dry salt begins to lose carbon dioxide at 100° C. (212° F.), and this loss increases at a higher temperature, until, at a red heat, the salt has lost 30·97 per cent. of its original weight, leaving a residue of carbonate, The pure salt, when dissolved in water, is at first neutral to litmus paper and to phenolphtalein test-solution, but the solution soon becomes feebly alkaline by partial conversion of the salt into carbonate. Sodium cobaltic nitrite test-solution produces in the aqueous solution a copious yellow precipitate. Tartaric acid test-solution, added to the aqueous solution in excess, causes a white, crystalline precipitate. A solution of 0·5 Gm. of Potassium Bicarbonate in 10 C.c. of water should not at once be colored red by one drop of phenolphtalein test-solution (limit of *carbonate*). Dissolve 2·5 Gm. of the salt in 30 C.c. of diluted acetic acid, and, having made up the volume to 50 C.c. with water, use 10 C.c. for each of the following tests: No visible change should occur in a portion of this solution upon the addition of an equal volume of hydrogen sulphide test-solution (absence of *metallic impurities*). The addition of 0·3 C.c. of potassium ferrocyanide test-solution to another portion should not produce a blue color within fifteen minutes (limit of *iron*). After adding a few drops of nitric acid and 0·1 C.c. of silver nitrate decinormal volumetric solution to another portion, and filtering, the further addition of silver nitrate volumetric solution should not affect the filtrate (limit of *chloride*). To

* "Take of Carbonate of Potassium *forty-eight troyounces;* Distilled Water *ten pints.* Dissolve the Carbonate of Potassium in the Distilled Water, and pass Carbonic Acid through the solution till it is fully saturated. Then filter the liquid, and evaporate that crystals may form, taking care that the heat does not exceed 160°. Lastly, pour off the supernatant liquid, and dry the crystals upon bibulous paper. Carbonic acid may be obtained from marble by the addition of dilute sulphuric acid." *U. S.* 1870.

neutralize 1 Gm. of Potassium Bicarbonate should require 10 C.c. of normal sulphuric acid (corresponding to 100 per cent of the pure salt), methyl-orange being used as indicator." *U. S.* "Colorless monoclinic prisms, not deliquescent, of a saline feebly alkaline taste. It is soluble in 4 parts of cold *water*, but almost insoluble in *alcohol* (90 per cent.). It affords the reactions characteristic of potassium and of bicarbonates. Each gramme exposed to a low red heat leaves 0·69 gramme of a white residue, which requires for exact neutralization 10 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, aluminium, calcium, magnesium, sodium, nitrates, sulphates, or sulphides, and only the slightest reactions with the tests for iron or for chlorides. 20 parts by weight of Potassium Bicarbonate are neutralized by 14 parts of Citric Acid, and by 15 parts of Tartaric Acid." *Br.* When heated to redness it loses carbonic acid and returns to the state of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. This method was adopted in the U. S. Pharmacopœia of 1870 for obtaining the pure carbonate. When a perfect bicarbonate, its solution, unless heated, does not precipitate a solution of magnesium sulphate. This negative indication, however, cannot be depended upon as showing the absence of carbonate; for, according to Dr. Christison, no precipitate will be occasioned even when 50 per cent. of this impurity is present. Potassium bicarbonate does not decompose calomel. When dissolved in 40 parts of water, it produces a white haze merely with a solution of corrosive sublimate; but if it contain so much as a hundredth part of carbonate, a brick-red precipitate is immediately produced. (Christison.) Another way of detecting the presence of carbonate is to add pure glucose to a heated solution of the suspected bicarbonate. If any carbonate be present, the mixture will turn yellow or brown. (Chevallier.) The official test (Hirsch's) given above is, however, more reliable, and admits but traces of carbonate. Potassium bicarbonate consists of one atom of potassium and one of hydrogen, in combination with one carbonic acid group, CO_3.

Medical Properties. The medical properties of this salt are similar to those of the carbonate, to which it is preferable from its milder taste and its greater acceptability to the stomach. The dose is from twenty grains to a drachm (1·3–3·9 Gm.). It is, however, much more disagreeable than the salts of potassium made from the fruit acids which are now universally used when a decided effect upon the system is desired, the bicarbonate and the carbonate being employed almost exclusively as antacids.

POTASSII BICHROMAS. U. S., Br. Potassium Bichromate. [Potassium Dichromate.]

$K_2Cr_2O_7$; **293·78.** (PŌ-TĂS'SI-Ī BĪ-ĊHRŌ'MĂS.) $K_2Cr_2O_7$; 294·8.

"Potassium Bichromate, K_2CrO_4,CrO_3, is obtained by roasting chrome ironstone with lime in the presence of air, and by treating the resulting chromate with a potassium salt, and subsequently with an acid." *Br.*

Red Chromate of Potash (Potassa); Kali Bichromicum, Kali Chromicum Rubrum; Bichrômate de Potasse, *Fr.*; Zweifach Chromsaures Kali, Doppeltchromsaures Kali, *G.*

This salt is most conveniently prepared from the neutral or yellow *potassium chromate*, by acidulating its solution with sulphuric acid and setting it aside for a day or two. In the action which follows we may suppose two reactions to take place: $(K_2CrO_4)_2 + H_2SO_4 = K_2SO_4 + (KHCrO_4)_2$, $(KHCrO_4)_2 = K_2Cr_2O_7 + H_2O$. Here the sulphuric acid, taking half the base from the two molecules of neutral chromate, changes them into two molecules of an acid chromate. This, however, is unstable, and the two molecules condense to form one of the dichromate with the elimination of one molecule of water. The yellow chromate is obtained by igniting four parts of powdered chrome-iron ore (FeO,Cr_2O_3) with one part of potassium nitrate, and lixiviating the resulting mass with water. The solution, by evaporation, yields the yellow salt in crystals. In this process, the nitric acid of the potassium nitrate furnishes oxygen to convert the chromium sesquioxide into chromic acid, which then unites with the potassium of the same salt. The iron, in the mean time, is sesquioxidized and rendered insoluble. Sometimes impure potassium carbonate (pearlash) is substituted for part of the potassium nitrate in the calcination. Omitting the potassium nitrate entirely, Stromeyer, of Norway, in performing the ignition, has used lime along with the pearlash, with economical results. When lime is employed, calcium chromate is formed, which is extracted by lixiviation and decomposed by a soluble potassium salt. When desired, the bichromate may be obtained directly from the solution of potassium chromate, derived from the treatment of the ore by acidulating it with sul-

phuric acid, without first crystallizing it. The production of chrome ore in the United States has practically ceased, as the California deposits are no longer worked. The manufacture of potassium and sodium bichromates is therefore carried on with imported ore brought chiefly from Asia Minor. The amount of the ore so imported in 1895 was 5230 tons, valued at $82,845; in 1896, 8869 tons, valued at $187,400; in 1897, 11,566 tons, valued at $186,313. In 1897, 71,220 pounds of chromic acid were also imported.

Potassium bichromate is in the form of "large, orange-red, transparent, triclinic prisms or four-sided tables, odorless, and having a bitter, metallic taste. Permanent in the air. Soluble in 10 parts of water at 15° C. (59° F.), and in 1·5 parts of boiling water; insoluble in alcohol. The salt fuses below a red heat, without loss of weight, forming a dark-brown liquid. At a white heat it evolves oxygen and leaves a residue of neutral potassium chromate and green chromic oxide. The aqueous solution (1 in 20) has an acid reaction upon litmus paper. On mixing 4 C.c. of the aqueous solution with 0·5 C.c. of alcohol, and then with 1 C.c. of sulphuric acid, the liquid will assume a green color and emit the odor of aldehyde. Sodium cobaltic nitrite test-solution produces in the aqueous solution a copious yellow precipitate." *U. S.* "Potassium Bichromate dissolved in *water* gives a yellowish-white precipitate with *solution of barium chloride*, and a purplish-red precipitate with *solution of silver nitrate*, the filtrate from either solution affording the reactions characteristic of potassium, and each precipitate being entirely soluble in *diluted nitric acid* (absence of sulphates and chlorides). The aqueous solution, digested with *sulphuric acid* and ethylic alcohol, or with many other organic compounds, acquires an emerald-green color. 5·66 grammes of *ferrous sulphate*, dissolved in a little *water* and acidulated with *sulphuric acid*, should not cease to yield a blue color with solution of *potassium ferricyanide* until such a quantity of solution as contains 1 gramme of the Potassium Bichromate has been added." *Br.*

Medical Properties. Potassium bichromate is an irritant caustic. It was first used internally in 1850, by M. Robin, as an alterative in *secondary syphilis*, in doses of one-fifth of a grain (0·012 Gm.), given in pill form; and Prof. Heyfelder, of Erlangen, and M. Vicente afterwards employed it in the same disease with asserted encouraging results. It is said to cause salivation; but it is at present never used internally. Its saturated solution was recommended, in 1827, by Dr. Cumin, as a caustic application to *tubercular elevations*, *excrescences*, and *warts*, and in 1850 by M. Puche in *syphilitic vegetations*. It causes the morbid parts to shrivel and fall off. Dissolved in water, in the proportion of five grains gradually increased to a drachm to the fluidounce, it has been found useful in affections of the mucous membranes requiring astringents; and a solution has also been used with advantage for correcting the fetor of *sloughing wounds*.*

In overdoses it operates as a violent irritative and corrosive poison, producing severe vomiting, frequent dark hemorrhagic dejections, violent abdominal pains, pronounced disturbance of the circulation, coma, heart-failure, collapse, etc. Less than an ounce has caused unconsciousness in five minutes, with death thirty-five minutes later. (*Brit. Med. Journ.*, ii. 1888.) Soap, an alkaline carbonate, or magnesia, is the antidote. Potassium bichromate is manufactured largely for the use of calico-printers. The workmen engaged in making it are liable to painful ulcerations of the hands; and, in consequence of the acrid vapors evolved, violent irritation of the nostrils is apt to be experienced, with severe pricking sensations and excessive sneezing, followed in time by destruction of the mucous membrane and even of the septum itself. It is asserted that this result may be avoided by breathing through the mouth exclusively, the profuse secretion of saliva produced carrying off the poisonous particles. (*B. and F. Med.-Chir. Rev.*, Oct. 1863.) For a full account of the manufacture of the chromium salts, for dyes and pigments, see *P. J. Tr.* (xv. 32).

POTASSII BITARTRAS. U. S. (Br.) Potassium Bitartrate. [Cream of Tartar.]

$KHC_4H_4O_6$; 187·67. (PŌ-TĂS'SĮ-Ī BĪ-TĂR'TRĂS.) $KHC_4H_4O_6$; 188.

"Acid Potassium Tartrate, $(CHOH)_2COOH.COOK$, is obtained from the crude cream of tartar which is deposited during the fermentation of grape juice, and from the lees of wine." *Br.*

Potassii Tartras Acidus, *Br.*, Acid Potassium Tartrate, Supertartrate of Potassa, Crystals of Tartar, Cream of Tartar; Tartaras Depuratus, *P. G.*; Kali Bitartaricum, Bitartras Potassicus, s. Kalicus, Cremor Tartari; Tartrate

* *Mueller's Fluid* is used for preserving anatomical specimens. It consists of from 2 to 2·5 parts of potassium bichromate, 1 part of sodium sulphate, and 100 parts of water.

acide de Potasse, Crême de Tartre, Bitartrate de Potasse, Pierre de Vin, *Fr.;* Doppeltweinsaures Kali, Weinsteinrahm, Weinstein, *G.;* Cremore di Tartaro, *It.;* Cremor de Tartaro, *Sp.*

During the fermentation of wines, especially those that are tart, a peculiar matter is deposited in the casks, forming a crystalline crust, called *crude tartar*, or *argol*. That deposited from red wines is of a reddish color, and called *red tartar;* while that derived from white wines is of a dirty-white color, and denominated *white tartar*. Both kinds consist of potassa, united with an excess of tartaric acid, forming acid potassium tartrate, rendered impure by calcium tartrate, more or less coloring matter, and other matters which are deposited during the clarification of the wine. The deposition of the tartar is thus explained. The acid tartrate exists naturally in the juice of the grape, held in solution by saccharine matter. When the juice is submitted to fermentation in the process for converting it into wine, the sugar disappears, and is replaced by alcohol, in which the salt is insoluble. It is from this substance that acid potassium tartrate is obtained by a process of purification. The importation of crude tartar, or argol, for the year 1895 was 27,911,122 lbs., valued at $1,893,780; for 1896, 28,481,665 lbs., valued at $2,724,709; for 1897, 23,457,576 lbs., valued at $1,967,042. Although the amount of crude tartar produced in the United States is small, compared with the quantity imported from Europe, yet the amount from American wines is rapidly increasing. The process for purifying crude tartar is founded upon the greater solubility of acid potassium tartrate in hot than in cold water. The tartar, previously pulverized, is boiled with water in copper boilers. The solution, when saturated, is transferred to earthen pans, where it deposits on cooling a crystalline layer, nearly free from color. This is redissolved in boiling water, and the solution, having been mixed with 4 or 5 per cent. of pipe-clay,* is evaporated to a pellicle. The clay precipitates with the coloring matter, and the clear solution, as it cools, deposits white crystals in crusts, which, upon being exposed to the air on linen for several days, acquire an increased degree of whiteness. These constitute the *crystals of tartar* of pharmacy. The salt, as met with in commerce, is generally, for greater convenience, in the form of powder, to which the name *cream of tartar* properly belongs. (See *Bull. Pharm.*, 1898, 405.) Wittstein proposes to free cream of tartar from lime by dilute hydrochloric acid, which dissolves the lime preferably, and, if not used in excess, will take up very little of the potassium salt.

Properties. Potassium bitartrate occurs in commerce in white crystalline crusts or masses of aggregated crystals, which are usually powdered before being sold to pharmacists. It is officially described as in "colorless or slightly opaque, rhombic crystals, or a white, somewhat gritty powder, odorless, and having a pleasant, acidulous taste. Permanent in the air. Soluble in about 201 parts of water at 15° C. (59° F.), and about 16·7 parts of boiling water; very sparingly soluble in alcohol. When a small portion of the salt is heated on platinum foil, it chars and emits inflammable vapors having the odor of burning sugar. At a higher temperature, with free access of air, the carbon of the black residue is oxidized, and a white, fused mass of potassium carbonate remains, which has an alkaline reaction, and effervesces strongly with acids. The aqueous solution of the salt has an acid reaction upon litmus paper. With sodium cobaltic nitrite test-solution it yields a copious yellow precipitate. In the aqueous solution of the salt, rendered neutral by potassium or sodium hydrate test-solution, silver nitrate test-solution produces a white precipitate which, on boiling, becomes black by the separation of metallic silver. If, before applying heat, enough ammonia water be added to dissolve the white precipitate, upon boiling the solution a mirror will be deposited on the sides of the test-tube." *U. S.* "A gritty white powder, or fragments of cakes crystallized on one surface, with an acid taste. Soluble in 200 parts of cold *water*, insoluble in *alcohol*. It affords the reactions characteristic of potassium and of tartrates. Each gramme of the dry salt should require for neutralization at least 5·2 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no characteristic reaction with the tests for lead, copper, or iron, and only the slightest reaction with the tests for calcium, magnesium, sodium, chlorides, or sulphates. The total amount of impurities should not exceed 2½ per cent. of the dried salt." *Br.* With salifiable bases which form soluble tartrates, it gives rise to double salts, consisting of neutral potassium tartrate, and the tartrate of the base added. Several of these are important medicines. Cream of tartar, though sparingly soluble in water, becomes abundantly so by the addition of borax or boric acid.† (See *Sodii Boras.*)

* The use of egg albumen and animal charcoal is also availed of for this clarifying and decolorizing.

† *Soluble Tartar. Tartarus boraxatus, s. Kali tartaricum boraxatum, s. Cremor tartari solubilis.* Borax, 2 parts; distilled water, 20 parts. Dissolve, and add 5 parts purified cream of tartar. Agitate to dissolve, filter, evaporate to dryness, and powder.

Tests. "If 1·5 Gm. of the salt be shaken with 30 C.c. of water and the mixture filtered, 10 C.c. of the filtrate, after being acidulated with nitric acid, should not be rendered turbid by 0·5 C.c. of silver nitrate test-solution (absence of *chloride*), nor by 0·5 C.c. of barium chloride test-solution (absence of *sulphate*). A solution of 0·5 Gm. of the salt in 3 C.c. of ammonia water should leave no insoluble residue (absence of *insoluble matter*), nor be affected by ammonium sulphide test-solution (absence of *copper*, *lead*, *iron*, etc.). If 1·2 Gm. of Potassium Bitartrate be repeatedly agitated, during half an hour, with a mixture of 5 C.c. of acetic acid and 1 C.c. of water, and the mixture be then diluted with 30 C.c. of water, and filtered, the clear filtrate should not be rendered turbid, within one minute, by the addition of 0·5 C.c. of ammonium oxalate test-solution (limit of *calcium salt*). The odor of ammonia should not be evolved on heating the salt with a slight excess of potassium or sodium hydrate test-solution. If 1·88 Gm. of Potassium Bitartrate be thoroughly ignited at a red heat, it should require for complete neutralization not less than 9·9 C.c. of normal sulphuric acid (each C.c. corresponding to 10 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.*

The cream of tartar of commerce is not pure potassium bitartrate. It usually contains from 2 to 7 per cent. of calcium tartrate, an amount admissible in samples for medicinal use. But it sometimes contains from 8 to 13 per cent. of calcium tartrate, the amount being especially large in tartar from Spanish wines and those from the south of France. It is often purposely mixed with various substances, such as sand, clay, gypsum, flour, chalk, alum, and potassium sulphate. Sand, clay, and gypsum may be detected by their insolubility in a hot solution of potassa; flour, by its striking a blue color with iodine; chalk, by its effervescing with dilute acids; alum (an unlikely sophistication), by its astringency; and any soluble sulphate, by its causing a precipitate with barium chloride, not entirely soluble in nitric acid. The action of the last-mentioned test is explained by the fact that the barium tartrate is soluble and the sulphate insoluble in nitric acid. Another sophistication of cream of tartar is said to be with sugar of milk, but this cannot often happen, because of the cost of the latter. The best security against fraud is to purchase the crystals and have them powdered. Geo. F. Payne examined commercial cream of tartar; of ten samples obtained from grocery stores, five contained no cream of tartar whatever. Some of the spurious samples were mainly composed of a mixture of dried alum and acid calcium phosphate. (*Proc. A. P. A.*, 1897, 695.) The U. S. Pharmacopœia 1890 admits a slight impurity. It should contain 99 per cent. of pure potassium bitartrate.

Composition. Cream of tartar consists of one molecule of tartaric acid, $C_4H_4O_6.H_2$, in which one of the two replaceable hydrogen atoms has been replaced by an atom of potassium.

Medical Properties and Uses. Potassium bitartrate is a very mild saline cathartic, and an active, soothing, hydragogue diuretic. In small doses it acts as a cooling aperient and in large ones as a hydragogue cathartic, producing copious watery stools. It is much used in *dropsy*. It is frequently prescribed in combination with senna, sulphur, or jalap. (See *Confectio Sulphuris* and *Pulvis Jalapæ Compositus*.) Its solution in boiling water, sweetened with sugar and allowed to cool, forms an acid, not unpleasant, refrigerant drink, advantageously used in some *febrile affections*, and frequently employed as a domestic remedy. The beverage called *imperial* (*potus imperialis*) is a drink of this kind, made by dissolving half an ounce of the salt in three pints of boiling water, and adding to the solution four ounces of white sugar and half an ounce of fresh lemon-peel. *Cream of tartar whey* is prepared by adding about two drachms of the bitartrate to a pint of milk. It may be given, diluted with water, in dropsical complaints. The dose of cream of tartar is a drachm or two (3·9–7·8 Gm.) as an aperient; and from half an ounce to an ounce (15·5–31·1 Gm.) as a hydragogue cathartic, mixed with molasses, or suspended in water. As a diuretic in dropsical cases, it may be given in the dose of a drachm and a half or two drachms (5·9–7·8 Gm.) several times a day. It is believed to escape from the system unchanged, and hence is not available when an alkaline influence upon the blood or renal secretion is desired. In pharmacy, cream of tartar is employed to obtain the neutral potassium tartrate (soluble tartar), potassium and sodium tartrate (Rochelle salt), antimony and potassium tartrate (tartar emetic), and iron and potassium tartrate (tartarized iron). Deflagrated with potassium nitrate, or incinerated alone, it is converted into a pure form of potassium carbonate, called salt of tartar. In the laboratory it is used to procure potassa in a pure state, and for making black and white flux. *Black flux* is prepared by deflagrating cream of tartar with half its weight of potassium nitrate; and *white flux*, by deflagrating it with twice its weight of the same salt.

POTASSII BROMIDUM. U. S., Br. Potassium Bromide.

KBr; 118·79. (PŌ-TĂS'SĮ-Ī BRŌ'MĮ-DŬM.) KBr; 118·8.

"Potassium Bromide, KBr, may be obtained by adding a slight excess of bromine to a strong solution of potassium hydroxide, evaporating the solution of potassium bromide and bromate to dryness, decomposing the bromate by fusing the mixture with charcoal, and purifying by crystallization." *Br.*

Bromide of Potassium; Kalium Bromatum, *P. G.;* Bromuretum Potassicum, s. Kalicum; Bromure de Potassium, *Fr.;* Bromkalium, *G.*

In the first step of the U. S. process of 1870 * a solution of ferrous bromide was formed, and this, by the addition of the solution of potassium carbonate, was decomposed so as to produce ferrous carbonate, which precipitated, and potassium bromide, which remained in solution. By straining, the precipitated carbonate was separated, and from the strained liquor potassium bromide was obtained by due evaporation. In the Br. Ph. 1885, by reaction between potassa and bromine, the potassium bromide and bromate are produced in solution, and, having been obtained dry by evaporation, are exposed with the powder of charcoal to a red heat, whereby the potassium bromate is converted into potassium bromide by the separation of its oxygen. The remainder of the process consists in obtaining the bromide in crystals by solution in boiling water, which deposits it on cooling. "Potassium Bromide should be kept in well-stoppered bottles." *U. S.*

Properties. Potassium bromide is in "colorless or white, cubical crystals, or granules, odorless, and having a pungent, saline taste. Permanent in the air. Soluble, at 15° C. (59° F.), in about 1·6 parts of water, and in 200 parts of alcohol; in less than 1 part of boiling water, and in 16 parts of boiling alcohol; also soluble in 4 parts of glycerin. On heating the salt upon platinum foil, it decrepitates; near 700° C. (1290° F.) it fuses without decomposing, and at a bright red heat it volatilizes, communicating a violet color to the flame. The aqueous solution (1 in 20) is neutral, or has, at most, only a scarcely perceptible alkaline reaction upon litmus paper. The addition of tartaric acid test-solution, or of sodium bitartrate test-solution, produces in it, after some time, a white crystalline precipitate. Sodium cobaltic nitrite test-solution produces in it at once a copious yellow precipitate. If to 10 C.c. of the aqueous solution of the salt a few drops of chloroform be added, then 1 C.c. of chlorine water, and the mixture be agitated, the liberated bromine will dissolve in the chloroform, imparting to it a yellow or brownish-yellow color without a violet tint." *U. S.* "Soluble in 2 parts of cold *water*, and in 200 parts of *alcohol* (90 per cent.). It affords the reactions characteristic of potassium and of bromides. Each gramme, dissolved in *water*, requires for complete precipitation not less than 83·7 nor more than 85·4 cubic centimetres of the *volumetric solution of silver nitrate*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, zinc, calcium, magnesium, sodium, ammonium, bromates, iodates, or cyanides, and only the slightest reactions with the tests for chlorides, iodides, or sulphates. *Test-solution of ferric chloride* should not cause a red coloration in the cold aqueous solution (absence of thiocyanates.)" *Br.* According to Mr. Chas. D. Chase, the commercial salt often is decidedly alkaline, and will precipitate the alkaloids from the solution of their salts: a serious mishap from such cause is very conceivable.

Tests. To determine the percentage of chloride in an impure bromide the process of M. Baudrimont, as improved by M. Falières, may be used. It is founded upon the fact that chlorides precipitate more silver than the bromides, because of the lower atomic weight of chlorine as compared with bromine; for an explanation see *P. J. Tr.*, 1872, p. 542. Prepare a titrated solution of 0·852 gramme of silver nitrate in 100 cubic centimeters of distilled water. It is necessary, by means of ferric chloride, salts of barium, and strong sulphuric acid in excess, to insure that there are present no other salts, such as potassium iodide, carbonate, or sulphate, or sodium nitrate, which shall interfere with the results. Then dissolve one gramme of the bromide in thirty or forty grammes of water in a stoppered bottle, and add 1·427 grammes of silver nitrate in solution. When the precipitate has subsided, add, drop by

* "Take of Bromine *two troyounces;* Iron, in the form of Filings, *a troyounce;* Pure Carbonate of Potassium *two troyounces and sixty grains;* Distilled Water *four pints.* Add the Iron, and afterwards the Bromine, to a pint and a half of the Distilled Water, stirring the mixture frequently with a glass rod for half an hour. Apply a gentle heat, and, when the liquid assumes a greenish color, add gradually the Pure Carbonate of Potassium, previously dissolved in a pint and a half of the Distilled Water, until it ceases to produce a precipitate. Continue the heat for half an hour, and then filter. Wash the precipitate with the remainder of the Distilled Water, boiling hot, and again filter. Mix the filtered liquids, and evaporate that crystals may form. Lastly, pour off the mother-water, and, having dried the crystals on bibulous paper, keep them in a well-stopped bottle." *U. S.* 1870.

drop, from a Gay-Lussac burette the titrated solution. If the bromide be pure, no precipitate forms; otherwise the number of cubic centimeters required to completely precipitate it equals the percentage of the chloride. An iodide of alkaline metal may be detected by adding to the solution of the bromide the palladium chloride, which will precipitate all the iodine in the form of palladium iodide, while the bromide of that metal will remain in solution. (*Ibid.*) According to MM. Bobieure and Herbelin, potassium bromide containing iodide may be purified by boiling with bromine water and evaporating, the liberated iodine and the excess of bromine being driven off during the evaporation. (*Journ. de Pharm.*, 4e sér., x. 166.) The U. S. Pharmacopœia permits the presence of 3 per cent. of chloride in potassium bromide, but insists on the absence of iodide and bromate. "If 1 Gm. of the salt be dissolved in 10 C.c. of a mixture of 100 C.c. of water and 0·2 C.c. of normal sulphuric acid, no red tint should be imparted to the solution by the addition of a few drops of phenolphtalein test-solution (limit of *potassium carbonate*). If a little of the salt be held in a non-luminous flame on a perfectly clean platinum wire, the flame should be colored violet at once, without any appearance of yellow (absence of *sodium*). If diluted sulphuric acid be dropped upon crushed crystals of the salt, they should not at once assume a yellow color (absence of *bromate*). If 10 C.c. of the aqueous solution (1 in 20) of the salt be mixed with a little starch test-solution, the addition of a few drops of chlorine water should not produce a blue color (absence of *iodine*). Ten C.c. of the aqueous solution (1 in 12) should not be rendered turbid by the addition of 0·5 C.c. of ammonia water and of 0·5 C.c. of ammonium sulphide test-solution (absence of *iron*, *aluminum*, etc.); nor should 10 C.c., after being slightly acidulated with acetic acid, be rendered turbid by an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *lead*, *copper*, etc.); nor by 0·5 C.c. of ammonium oxalate test-solution (*calcium*); nor by 0·5 C.c. of potassium sulphate test-solution (*barium*); nor by 0·5 C.c. of barium chloride test-solution (*sulphate*); nor be colored blue by 0·5 C.c. of potassium ferrocyanide test-solution (*iron*). If 0·5 Gm. of the well-dried salt be dissolved in 10 C.c. of water, and 2 drops of potassium chromate test-solution be added, it should not require more than 42·85 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color of silver chromate (absence of more than 3 per cent. of *chloride*)." *U. S.*

Medical Properties. When given to either cold- or warm-blooded animals in repeated doses of sufficient amount, potassium bromide produces a condition of universal depression, with failure of the circulation, progressively increasing paralysis, lowering of temperature, and finally death from asphyxia or exhaustion. In man the remedy causes similar results,—the series of phenomena being known as *bromism*. The symptoms are muscular weakness, general mental and bodily sluggishness, loss of memory, often marked sleepiness, depression of spirits deepening into complete apathy, lowering of temperature, and finally a universal depression of function, the patient lying in bed scarcely more than a feeble automaton. Fetor of breath is usually well marked, and an eruption of acne may be the first indication of the constitutional action of the drug. In some cases the effects of the drug upon the skin are most marked, and the pustules, under its continuous exhibition, become furuncular or go on to ulceration. It seems to be proved that the bromide affects the whole nervous system, but that the portions most susceptible to its influence are those tissues of the spinal cord whose function it is to receive the impulse from without, and the peripheral ends of the afferent or sensitive nerves. Its action upon the circulation has not been clearly determined, but it is somewhat probable that in small doses it contracts, in large ones relaxes, the capillaries; in sufficient amount it lessens the force of the heart's beats. It is probably eliminated with all the secretions, having been found in the sweat, saliva, urine, and intestinal mucus. When taken largely for some time it accumulates in the system, and it has been found in the urine a month after the ingestion of the last dose. It has been employed in almost all diseases to which human flesh is heir; but experience has shown that it is chiefly valuable as a means of quieting non-inflammatory excitement of the reflex centres of the cord, of the peripheral afferent nerves, of the genital function, and of the cerebrum. It is especially valuable in *epilepsy*, in which disease, however, it is necessary to maintain its decided action for years. In various forms of *convulsions*, such as *hysterical*, *infantile*, and *puerperal*, it is often of great service. In *tetanus* and *strychnine poisoning*, if given with sufficient boldness, it is an excellent remedy. In general nervous excitement,—or unrest,—in *delirium tremens*, in *nymphomania*, *satyriasis*, and other forms of genital irritation without inflammation, and in *semi-impotence* from over-irritability of the sexual organs, it is of great service. Given with opium it will often avert the secondary nausea which that narcotic produces in some persons. In *reflex vomiting*, as that of pregnancy, it is often of advantage. According to Dr.

J. T. Rothrock, it is of service in preventing the so-called *urethral fever* produced in some very susceptible males by the passage of a catheter or bougie. It was formerly used as an alterative and resolvent in *syphilis*, *scrofula*, *bronchocele*, and other affections; but this employment of it has passed entirely out of vogue.

Potassium bromide may be given, dissolved in water, in doses of from twenty grains to a drachm (1·3–3·9 Gm.) three times a day. In some cases much larger amounts are required. In severe strychnine poisoning a half-ounce (15·5 Gm.), properly diluted, may be exhibited at once; and in tetanus there is little use in giving less than the same amount in the twenty-four hours.

POTASSII CARBONAS. U. S., Br. Potassium Carbonate.

K_2CO_3; 137·91. (PŌ-TĂS'SĬ-Ī CĂR'BŌ-NĂS.) K_2CO_3; 138.

Carbonate of Potassa from Pearlash; Kali Carbonicum, Carbonas Potassicus, s. Kalicus; Carbonate de Potasse, *Fr.*; Kohlensaureskali, *G.*

The British Pharmacopœia defines this salt as "K_2CO_3, associated with either one or two molecules of water," and states that "it may be obtained from the ashes of wood, or by the interaction of crude potassium sulphate and crude calcium carbonate and carbon." The present U. S. Pharmacopœia does not give a process for this salt.*

The object of the process is to purify the impure potassium carbonate, or pearlash. This generally contains certain insoluble impurities, as well as small portions of potassium sulphate, silicate, and chloride, as explained under another head. (See *Potassii Carbonas Impura.*) By dissolving it in a due proportion of water, and filtering the solution, the insoluble impurities are disposed of, as well as the greater part of the foreign salts, which, being much less soluble than the potassium carbonate, are excluded by the superior affinity of this salt for the water. The proper way of conducting the purification is to mix the impure carbonate with an equal weight of *cold water*, and to allow the mixture to stand for a day or two, stirring it frequently to promote the action of the water. The clear liquor obtained by decantation or filtration is then evaporated to dryness. The former official process was conducted very much in this way, cold water being employed, and about equal weights of alkali and water being used. The prolonged contact of the water with the salt, and the occasional stirring of the mixture, formerly ordered by the Dublin College, were useful directions. In no case should the undissolved residue be washed with a fresh portion of water, as by such a proceeding the foreign salts, which it is the object of the process to separate, would be dissolved. Iron vessels are directed, because this metal is not acted on by the alkali, while glass is attacked by it. In granulating the salt by stirring, it is better, when the solution is brought nearly to dryness, to keep it on the fire at a reduced heat until the process is finished, than to remove it the moment it thickens. According to Berzelius, a more productive process for purifying pearlash, though the resulting salt is not so pure as when obtained in the way just described, is to dissolve the pearlash in more than its weight of water, to evaporate the solution till it has the sp. gr. 1·52, and then to put it in a cool place, that the foreign salts, principally potassium sulphate and chloride, may crystallize. The solution is then decanted, and evaporated to dryness. To get rid of the silica, Rieckher proposes to evaporate the solution, exempt from sulphate, to dryness, to moisten the residue with solution of ammonium carbonate, and again evaporate. The silica separates, and passes into the insoluble state at the temperature necessary for evaporation. By again dissolving and evaporating, the carbonate is obtained free from this impurity. (*Chem. Centralbl.*, 1863, p. 158.) "Potassium Carbonate should be kept in well-stoppered bottles." *U. S.*

Properties. "A white, granular powder, odorless, and having a strongly alkaline taste; very deliquescent. Soluble in 1·1 parts of water at 15° C. (59° F.), and in about 0·65 part of boiling water; insoluble in alcohol. When heated to 130° C. (266° F.), the salt loses all the water which it may have retained or absorbed; at a bright red heat it melts, and at a white heat it volatilizes, communicating to the flame a pure violet color. Its aqueous solution (1 in 20) has a strongly alkaline reaction upon litmus paper, and effervesces with acids. With excess of tartaric acid test-solution it slowly yields a white, crystalline precipitate; with sodium cobaltic nitrite test-solution a copious yellow precipitate is formed at once." *U. S.* It is extremely deliquescent; and hence a portion of it, exposed to the air for some time, attracts so much water as to dissolve completely into an oily liquid, called by the older chemists *oleum*

* "Take of Impure Carbonate of Potassium [pearlash] *thirty-six troyounces*; Water *two pints and a half*. Dissolve the Impure Carbonate in the Water, and filter the solution; then pour it into an iron vessel, and evaporate over a gentle fire until it thickens. Lastly, remove it from the fire, and stir constantly with an iron spatula so as to form a granular salt." *U. S.* 1870.

tartari per deliquium. On account of this property, potassium carbonate should be kept in bottles with accurately-ground stoppers. The usual impurities are earthy matters, potassium sulphate and chloride, and silica in the state of potassium silicate.

Tests. "When a small portion of the salt, treated with a drop of hydrochloric acid, is introduced into a non-luminous flame on a perfectly clean platinum wire, the flame should be colored violet at once, without any appearance of yellow (absence of *sodium*). No residue should be left on dissolving 1 Gm. of the salt in 20 C.c. of water (absence of *earthy impurities*). No precipitate or coloration should be produced in the aqueous solution (1 in 20) by an equal volume of hydrogen sulphide test-solution (absence of *metallic impurities*). On neutralizing the solution with hydrochloric acid, no odor of burning sulphur, nor any white precipitate, should appear (absence of *hyposulphite*). If 2 C.c. of the aqueous solution (1 in 20) be carefully mixed with an equal volume of concentrated sulphuric acid, and, after cooling, 1 C.c. of ferrous sulphate test-solution be poured upon it so as to form a separate layer, no brown color should appear at the line of contact (absence of *nitrate*). If 0·5 Gm. of Potassium Carbonate be dissolved in 5 C.c. of diluted hydrochloric acid and 5 C.c. of water, the addition of 1 C.c. of barium chloride test-solution should not produce any turbidity (absence of *sulphate*). A solution of 0·5 Gm. of the salt in 5 C.c. of diluted hydrochloric acid mixed with 5 C.c. of water should not be colored blue within fifteen minutes by 0·3 C.c. of potassium ferrocyanide test-solution (limit of *iron*). If 0·5 Gm. of the salt be dissolved in 6 C.c. of diluted nitric acid and 4 C.c. of water, then 0·1 C.c. of silver nitrate decinormal volumetric solution be added, and the mixture filtered, no change should be produced in the filtrate by the further addition of silver nitrate volumetric solution (limit of *chloride*). If 10 C.c. of the aqueous solution (1 in 20) be mixed with 2 drops, each, of ferrous sulphate test-solution and ferric chloride test-solution, and the mixture heated, and slightly supersaturated with hydrochloric acid, no blue color should appear (absence of *cyanide*). The addition of a few drops of lead acetate test-solution to the aqueous solution should produce a pure white precipitate (absence of *sulphide*). To neutralize 0·69 Gm. of Potassium Carbonate should require not less than 9·5 C.c. of normal sulphuric acid (each C.c. corresponding to 10 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* The official test permits the presence of 5 per cent. of impurities. It is incompatible with acids and acidulous salts, ammonium chloride and acetate, lime water, calcium chloride, magnesium sulphate, alum, tartar emetic, silver nitrate, ammoniated copper and ammoniated iron, ferrous sulphate, tincture of ferric chloride, calomel and corrosive sublimate, lead acetate and subacetate, and zinc sulphate. It is not decomposed by iron and potassium tartrate. "Each gramme should require for neutralization at least 11·9 C.c. of volumetric solution of sulphuric acid. 2 grammes, after exposure to a red heat, should leave between 1·66 and 1·7 grammes of anhydrous potassium carbonate, K_2CO_3." *Br.* A solution of the salt, on exposure to the air, or on the addition of an acid, deposits flocculi consisting of hydrated silica, resulting from the decomposition of potassium silicate, which is always present as an impurity. The spontaneous deposition of silica is owing to the absorption of carbonic acid.

Composition. Potassium carbonate, after exposure to a red heat, is anhydrous, consisting of two atoms of potassium and one carbonic acid group, CO_3. Obtained by the official formulas, it is a hydrate, containing two mols. of carbonate and three of water. When exposed to the air, potassium carbonate absorbs sufficient water, before losing its solid form, to give it three mols.; with more it begins to deliquesce. (Dr. Pohl, *A. J. P.*, 1861, p. 532.)

Medical Properties and Uses. Purified pearlash is the form of potassium carbonate usually employed in this country, where it is frequently, though incorrectly, called *salt of tartar*, the latter name being strictly applicable to the purer carbonate obtained by decomposing cream of tartar. It is occasionally used as an antacid in *dyspepsia*, a diuretic in *dropsy*, and an antilithic in *uric acid gravel;* but the purpose to which it was most commonly applied in former years was the formation of the *neutral mixture* and the *effervescing draught*. It is also useful in some cases of *jaundice*, directly exciting the hepatic function. The dose is from ten to thirty grains (0·65–1·95 Gm.), given in some aromatic water sweetened with sugar. In large quantities it acts as a corrosive poison, and is capable of producing death in a few hours; three ounces in very concentrated solution have been recovered from by an adult female. (Dr. Espagne, *Arch. Gén.*, Fév. 1867.) The antidotes are the fixed oils and the vegetable acids. As a local remedy in *cutaneous affections*, potassium carbonate is used in the form of bath, lotion, and ointment. From eight to sixteen ounces may be used for a single bath, the quantity being gradually increased. Lotions may be made by dissolving two or three drachms in a pint of water; and ointments, by rubbing from ten grains to a drachm with an ounce of lard.

POTASSII CARBONAS IMPURA. U. S. 1870. Impure Carbonate of Potassium.

(PŌ-TĂS'SI-Ī CĂR'BŌ-NĂS IM-PŪ'RA.)

Pearlash, Pearlashes, Impure Potassa; Potasse du Commerce, *Fr.;* Rohe Pottasche, *G.;* Potasch, *Dutch;* Potaske, *Dan.;* Potaska, *Swed.;* Potassa del Commercio, *It.;* Cenizas claveladas, *Sp.*

The alkali potassa is the hydrate of the metal potassium. (See *Potassium.*) It exists in various states of purity admixed with carbonate. In its most impure state, it is the common potash or *potashes* of commerce. This, subjected to calcination, is rendered purer, and is then called *pearlash*, the form of the alkali designated by the name at the head of this article.

Natural State and Preparation. Potash and pearlash of commerce are procured largely from the ashes of wood by lixiviation, and the subsequent evaporation of the solution obtained. The alkali exists in the wood principally in the state of acetate, and, being of a fixed and incombustible nature, is left behind after the incineration. The wood is burnt on the ground, in a place sheltered from the wind. The ashes consist of a soluble and an insoluble portion. The soluble part is made up of potassium carbonate, together with potassium sulphate, phosphate, and silicate, and potassium and sodium chlorides; the insoluble portion, of calcium, aluminum, oxidized iron and manganese carbonate and phosphate, and a little carbonaceous matter that has escaped combustion. The ashes are lixiviated in barrels with the addition of a portion of lime, and the soluble substances above mentioned are taken up. The lixivium is then evaporated in large iron kettles, which for several days are kept constantly full. The evaporation is continued until the mass has become of a black color and of the consistence of brown sugar. It is now subjected to as powerful a heat as can be produced by the best wood fire for a number of hours, by which it is fused. During the fusion the combustible impurities are for the most part burnt out, and a gaseous matter is emitted, which agitates the more fluid part. When the fusion is complete, the liquid becomes quiescent, and looks like melted iron. It is now transferred, by means of large iron ladles, to iron pots, where it congeals in cakes. These are broken up and packed in tight barrels, and constitute the *potash* of commerce. If it is intended to make *pearlash*, the process is varied. In this case the black matter of the consistence of brown sugar, called *black salts* by our manufacturers, instead of being fused, is transferred from the kettles to a large oven-shaped furnace so constructed that the flame may play over the alkaline mass, which in the mean time is stirred by means of an iron rod. The ignition is in this way continued until the combustible impurities are burnt out, and the mass, from being black, becomes of a bluish-white color. (*Rogers.*)

The ashes of plants amount generally to not more than a few parts in the hundred; and of these a portion only consists of potassa. The different parts of the same vegetable, and, for a stronger reason, different plants, furnish variable quantities of ashes. Ligneous plants yield less than herbaceous, the trunk less than the branches, and the branches less than the leaves. The bark yields more ashes than the wood; and the leaves of trees which drop their foliage in winter yield more than the leaves of evergreens. The following table gives the quantity of potassa contained in the ashes of one thousand parts of the plants:

Pine . . . . . 0·45	Wheat straw . . . . . 4·18	Dry oak leaves . . . . . 24·0
Poplar . . . . . 0·75	Flax . . . . . 5·0	Common nettle . . . . . 25·0
Birch . . . . . 1·29	Rush . . . . . 5·08	Black elder . . . . . 25·5
Beech . . . . . 1·45	Common thistle . . . . . 5·37	Vetch . . . . . 27·5
Oak . . . . . 2·03	Vine branches . . . . . 5·5	Poke . . . . . 45·6
Oak bark . . . . . 2·08	Barley straw . . . . . 5·8	Wheat stalks . . . . . 47·0
Box . . . . . 2·26	Beech bark . . . . . 6·0	Stems of potatoes . . . . . 55·0
Willow . . . . . 2·85	Fern . . . . . 6·2	Wormwood . . . . . 73·0
Linden . . . . . 3·27	Indian corn stalks . . . . . 17·5	Fumitory . . . . . 79·0
Elm . . . . . 3·9	Sunflower stalks . . . . . 19·4	Angelica . . . . . 96·2
Maple . . . . . 3·9		

Commercial History. Potash and pearlash are made in those countries in which forests abound. Accordingly, the alkali has been extensively manufactured in Canada. In the United States, with the disappearance of our forests, its production has been greatly curtailed. While the exports at one time were very large, they have diminished so that in 1892 only 1,307,634 lbs. were exported. Some idea of the falling off in manufacture may be gained by comparing this output of 1892 with that of 1850, the year of greatest production, when 27,000,000 lbs. were exported from Canada alone. (See an interesting report on "Canadian Potash," by

Dr. T. D. Reed, *Proc. A. P. A.*, 1893, 126.) It is produced in considerable quantities in the northern countries of Europe, especially in Russia and on the shores of the Baltic. It is of different qualities as it occurs in commerce, and is distinguished by the country or place of manufacture, as *American*, *Russian*, *Dantzic potash*, etc. Within recent years the residues of beet-root molasses, after fermentation of the sugar and distillation of the spirit, have served as a source of potash. It is thus obtained in large quantity in Germany and France.

The *suint* of sheep's wool constitutes another source of potashes. Potassium sulphate, either the crude salt from the Stassfurt deposits or that obtained from the crude potassium chloride of the same locality, is also converted into carbonate by a process analogous to Leblanc's soda process. The principle of the ammonia soda process can also be applied to the crude potassium chloride of Stassfurt, with this difference in the practical operation, that, because of the ready solubility of the acid potassium carbonate, trimethylamine is used instead of ammonia, as the chloride of this base is much more soluble than is ammonium chloride. Potash has been extracted from feldspar by Prof. Fuchs, by igniting it with lime, which renders the alkali slowly soluble in water. Dr. E. Meyer, of Berlin, has found that the extraction is facilitated by digesting the united mass with water under a pressure of seven or eight atmospheres. (*P. J. Tr.*, June, 1857, p. 607.) Other minerals have recently become the sources of potassa salts, especially a deposit of mixed potassium and magnesium chlorides, overlying a bed of common salt, at Stassfurt, near Magdeburg, in Prussia. The sales of the Leopoldshall-Stassfurt works for 1896 and 1897 were as follows: 1896, potassium chloride 147,679 metric tons, potassium sulphate 13,889 metric tons, kieserite 25,198 metric tons, kainite and sylvite, crude, 802,586 metric tons, carnallite 60,504 metric tons; 1897, potassium chloride 142,314 metric tons, potassium sulphate 15,403 metric tons, kieserite 25,882 metric tons, kainite and sylvite, crude, 964,105 metric tons, carnallite 63,701 metric tons.

Properties. *Potash* is in the form of fused masses, of a stony appearance and hardness, and a caustic burning taste. Its color is variegated; but reddish and dark brown are the predominant hues. When exposed to the air, it absorbs moisture and deliquesces, and, if sufficiently long exposed, finally becomes liquid. *Pearlash* is of a white color, with usually a tinge of blue. As it occurs in commerce, it is in tight casks, containing about three hundred and fifty pounds, in which it forms one entire, hard, concrete mass. In commerce it is found in coarse powder, intermingled with lumps as dug out of the casks, presenting an opaque granular appearance, like table salt or Havana sugar. It is deliquescent, and has a burning alkaline taste. It is soluble in water, with the exception of impurities. The soluble matter in 100 grains of the salt of medium quality will neutralize about 58 grains of official sulphuric acid. It differs from potash principally in containing fewer combustible impurities and in being less caustic and deliquescent. The coloring matter of both these forms of alkali is derived from carbonaceous impurities and small portions of iron and manganese.

Composition. The basis of both potash and pearlash is potassium carbonate; but this is associated with certain salts and with insoluble impurities. Several varieties of potash found in commerce were analyzed by Vauquelin, whose principal results are contained in the following table. The quantity examined of each kind was 1152 parts.

Kinds of Potash.	Caustic Potassium Hydrate.	Potassium Sulphate.	Potassium Chloride.	Insoluble Residue.	Carbonic Acid and Water.
American potash	857	154	20	2	119
Russian potash	772	65	5	56	254
Pearlash	754	80	4	6	308
Dantzic potash	603	152	14	79	304

These results, calculated for 100 parts, show that the American potash contains 74 per cent. of pure hydrated alkali, and the Russian 67 per cent. Pearlash, it is seen, is more rich in carbonic acid than potash; and this result of analysis corresponds with the qualities of the two substances as prepared in the United States,—potash being known to be far more caustic than pearlash. Besides the impurities shown by the table, potassium phosphate and silicate and sodium chloride are present. Prof. J. U. Lloyd, in the *Proc. A. P. A.*, 1892, p. 190, gives the results of an examination of American commercial potashes: he found that what was sold in

the market as "first sorts" was largely adulterated with common salt, this addition made to the melted potash in the kettle tending to whiten the crude potash and give it increased value in the eyes of those consumers who judge merely by appearances and do not take the trouble to assay it. According to Mr. Stevenson Macadam, the potashes of commerce contain iodine and a trace of bromine, which shows that the forest trees from which the alkali is obtained must contain a very minute proportion of these non-metallic elements.

As the potash of commerce is valuable in the arts in proportion to the quantity of real alkali which it contains, it is important to possess an easy method of ascertaining its quality in that respect. The process by which this is accomplished is called *alkalimetry*. One of the best methods is by the use of a decinormal solution of oxalic acid (6·3 Gm. in a liter). A 50-C.c. burette, graduated to fifths, and a beaker will be required.

Prof. H. B. Parsons gives the following practical points about estimating the amount of hydrate or carbonate. "100 C.c. of the decinormal solution will neutralize one one-hundredth of the molecular weight, in grammes, of any alkaline hydrate or bicarbonate, or one two-hundredths of the molecular weight of any alkaline normal carbonate or oxide. The reason for weighing out $\frac{1}{2}\frac{1}{0}\frac{1}{0}$ of the molecular weight for normal carbonates is because the oxalic acid in one liter is only sufficient to saturate one atom of K in any hydrate or carbonate; the normal carbonates and the oxides of the alkalies contain *two* atoms of K, Na, etc., and, consequently, require twice the volume of acid solution for neutralization. Hence it is proper to weigh out of carbonates or oxides $\frac{1}{1}\frac{1}{0}\frac{1}{0}$ of $\frac{1}{2}$ their molecular weights when estimating their purity volumetrically. If the proper quantities are weighed and titrated, each C.c. of acid used shows one per cent. of the substance sought. In practice, weigh out the amount of alkaline hydrate theoretically equivalent to 100 C.c. of the acid used, add about 20 drops of cochineal tincture, and drop the acid from a burette into the aqueous solution of alkali until the purple color changes to the straw-yellow or amber color due to slight excess of acid. The number of C.c. of acid employed shows the percentage of pure salt. Beginners are often troubled to know the 'end-reaction,' because they do not know the exact shade of color showing the change from alkaline to acid reaction. To obviate this difficulty, select two beakers of the same size as those used in titration, place in each 100 C.c. of pure water and 20 drops of cochineal tincture. To one solution add a single drop of acid, and to the other add a single drop of alkali. By comparing the solutions titrated with these standard colors, it soon becomes easy to catch the neutral point. To secure greater accuracy, it is best to make several titrations and take the average as the true result. By dissolving the weighed amount of alkali in a definite measure of water, and taking aliquot parts, very little extra trouble is experienced. For instance, it is required to determine the percentage of pure K_2CO_3 in a commercial sample. Weigh accurately 0·690 gramme ($\frac{1}{1}\frac{1}{0}\frac{1}{0}$ of $\frac{1}{2}$ of 138), and add water to make 100 C.c. Then, by means of the burette, measure out into separate beakers four portions of 20 C.c. each. Rinse the burette thoroughly with water, then with a little of the standard oxalic acid, and fill with the standard acid. Having added the same amount of cochineal tincture to each solution, carefully run in the acid until the neutral point is obtained; the number of C.c. of acid used is, respectively, 19·7, 19·6, 19·6, 19·5, the average being 19·6. This average multiplied by five gives the percentage, 98. In the case of compounds which are variable mixtures of several salts, it is customary to state the results as all oxide, or hydrate, or carbonate. Potassii carbonas impura, U. S. P. 1870 (Pearlash), is a variable mixture of hydrate and carbonate, with more or less potassium sulphate, chloride, and silicate, with traces of organic matter, silica, iron, calcium, etc. The results do not show how much of the salt sought is actually present in that particular condition, but they do show to how much the mixture is equivalent; that is, how much of the required salt may be made from the mixture. If it is required to know how much potassium hydrate may be made from pearlash, weigh out 0·561 gramme, and if how much oxide, weigh out 0·471 gramme, and titrate with decinormal acid. The percentages thus obtained show the value of the pearlash for the purposes named. It will be noticed that alkalimetry gives no clue as to the nature of the impurities present in alkaline salts; these must be determined by qualitative and quantitative analysis." (*N. R.*, Oct. 1878.)

This method of testing the potash of commerce indicates its alkaline strength, assuming this to be dependent solely on potassa; but soda, a cheaper alkali, may be present as an adulteration, and its proportion is important to be known. To solve this problem, M. O. Henry proposes that the saturating power of a given weight should be first determined in relation to sulphuric acid, and afterwards the proportion of potassium carbonate in an equal weight, by first converting it into an acetate, and then precipitating the potassa by sodium perchlorate,

the reacting salts being in alcoholic solution. The precipitated potassium perchlorate indicates the proportion of potassium carbonate. The amount of the latter determines how much of the sulphuric acid was expended in saturating the potassa; and the soda is indicated by the amount of this alkali equivalent to the remainder of the acid. (*Journ. de Pharm.*, vii. 214.) Another method of detecting soda in the potash of commerce, proposed by Pagenstecher, is to convert the suspected alkali into a sulphate, and to wash the sulphate formed with a saturated solution of potassium sulphate. If the whole of the saline matter be potassium sulphate, the washing will cause no loss of weight; but if part of it be sodium sulphate, this will be washed away, on account of its solubility in a saturated solution of potassium sulphate. (*Ibid.*, Mars, 1848, p. 239.) Frémy has proposed potassium metantimoniate as a test for soda in potash. In applying this test the potash is converted into a neutral potassium chloride, and treated with a recent solution of the metantimoniate. If the alkali examined contain 2 or 3 per cent. of soda, a precipitate will be almost instantly formed. If a less proportion of soda be present, time and agitation will be necessary to effect the precipitation. Frémy states that by this test he can detect the half of 1 per cent. of soda in commercial potash. (*Philos. Mag.*, Oct. 1848, p. 325.) Good potash should not contain a proportion of chlorides indicating more than 2 per cent. of chlorine by the test of silver nitrate. If a larger proportion is shown, adulteration with common salt may be suspected. A standard solution of the silver salt may be made, a known measure of which shall be just sufficient to precipitate all the chlorine in a given weight of good potash, after having been supersaturated with nitric acid. If a further addition of the test causes a precipitate, the presence of too much chlorine is shown.

Pearlash, from its impurity, is never used as a medicine. Purified to a certain extent, it takes the name of potassium carbonate. (See *Potassii Carbonas.*)

POTASSII CHLORAS. U. S., Br. Potassium Chlorate.

$KClO_3$; 122·28. (PŌ-TĂS'SI-Ī ĊHLŌ'RĂS.) $KClO_3$; 122·4.

"Potassium Chlorate should be kept in glass-stoppered bottles, and *great caution should be observed* in handling the salt, as dangerous explosions are liable to occur, when it is mixed with organic matters (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances, and either heated directly or subjected to trituration or concussion." *U. S.** "Potassium Chlorate, $KClO_3$, is obtained by passing chlorine into water holding lime or magnesia in suspension, treating the clarified liquid with potassium chloride, and subsequently crystallizing the potassium chlorate." *Br.*

Chlorate of Potash; Kali Chloricum, *P.G.;* Kali Oxymuriaticum, Kali Muriaticum Oxygenatum, Chloras Potassicus, s. Kalicus; Hyperoxymuriate of Potassa; Chlorate de Potasse, *Fr.;* Chlorsaures Kali, *G.*

In the U. S. and Br. Pharmacopœias no processes are given for Potassium Chlorate.

The salt may be conveniently obtained by the process of Graham, which consists in mixing potassium carbonate with an equivalent quantity of calcium hydrate before submitting it to the action of chlorine. The gas is absorbed with avidity, and the mass becomes hot, while water is given off. The lime converts the carbonate into caustic potassa, and the reaction then takes place between six mols. of potassa and six atoms of chlorine, with the result of forming five mols. of potassium chloride and one of potassium chlorate, while three mols. of water are eliminated. ($6KOH + (Cl_2)_3 = 5KCl + KClO_3 + 3H_2O$.) The products are, therefore, calcium carbonate, potassium chloride, and potassium chlorate. The chloride and chlorate are separated from the carbonate by solution in hot water, and the chlorate from the chloride by priority of crystallization: a large proportion of the potassa is lost by being converted into potassium chloride. In the process now generally employed for the commercial manufacture of potassium chlorate this is obviated, as follows. Chlorine is passed into a solution of milk of lime having a specific gravity of 1·04 until the liquid is nearly saturated. The clear solution is evaporated until it has a specific gravity of 1·18, and then potassium chloride added, and the mixture boiled down until a specific gravity of 1·28 is attained. On cooling, crystals of potassium chlorate separate out. The reactions here are $6Ca(OH)_2 + (Cl_2)_6 = 5CaCl_2 + Ca(ClO_3)_2 + 6H_2O$, and $Ca(ClO_3)_2 + 2KCl = CaCl_2 + 2KClO_3$. *Pechiney's* improvement on this process is to separate the greater part of the calcium *chloride* from the calcium *chlorate* before adding the potassium chloride. For details, see *N. R.*, Feb. 1882.

* Tablets composed of potassium chlorate and ammonium chloride are very prone to explode violently after having been made some time, evidently on account of chemical decomposition and the sudden evolution of a large quantity of the gaseous constituents.

The potassium chlorate of commerce is also prepared by the reaction of solutions of potassium chloride and calcium hypochlorite, with the assistance of heat. The potassium chlorate crystallizes during the refrigeration of the liquor, and calcium chloride remains in solution ($2KCl + 3(Ca(OCl)_2 + CaCl_2) = 2KClO_3 + 6CaCl_2$). This process has been further improved in Muspratt and Eschellmann's English patents (*Journ. Soc. Chem. Ind.*, iii. pp. 349 and 445) by substituting magnesia for lime, as potassium chlorate is much less soluble in magnesium chloride solutions than in those of calcium chloride, and consequently much less chlorate is kept in solution. The process is said to increase the production of chlorate by from 15 to 20 per cent. For a full account of the improved methods, see *Thorpe's Dictionary of Applied Chemistry*, 1891, vol. i. 531. Potassium chlorate is also now made on a commercial scale by the electrolysis of potassium chloride solution, two companies having begun operations at Niagara Falls, while several others are operating under different patents in Europe. The reaction is most simply expressed as $6KCl + 3H_2O = KClO_3 + 5KCl + 6H$.

Properties. Potassium chlorate is in "colorless, lustrous, monoclinic prisms or plates, or a white powder, odorless, and having a cooling saline taste. Permanent in the air. Soluble in 16·7 parts of water at 15° C. (59° F.), and in 1·7 parts of boiling water; insoluble in absolute alcohol, and but slightly soluble in mixtures of alcohol and water. At 234° C. (453·2° F.) the salt fuses, and above 352° C. (665·6° F.) it is decomposed into oxygen and potassium perchlorate; above 400° C. (752° F.) all its oxygen is liberated, and a white residue of potassium chloride remains, amounting to 60·8 per cent. of the chlorate employed. This residue is readily soluble in water, and the solution yields a white, curdy precipitate with silver nitrate test-solution. The aqueous solution (1 in 20) of the salt is neutral to litmus paper. With excess of tartaric acid test-solution the solution slowly yields a scant, white, crystalline precipitate; with sodium cobaltic nitrite test-solution, or with platinic chloride test-solution, a copious yellow precipitate is produced at once. When introduced into a non-luminous flame on a clean platinum wire, Potassium Chlorate communicates to the flame a pure violet color, without admixture of yellow (absence of *sodium*). When heated with hydrochloric acid, the aqueous solution assumes a greenish-yellow color, and evolves chlorine. Separate portions, each of 5 C.c., of the aqueous solution (1 in 20) should not be rendered turbid by 0·5 C.c. of barium chloride test-solution (absence of *sulphate*); nor by 0·5 C.c. of ammonium oxalate test-solution (*calcium*); nor by 0·5 C.c. of silver nitrate test-solution (*chloride*); nor should an equal volume of hydrogen sulphide test-solution produce either a precipitate or a coloration (absence of *metals*). If a mixture of 1 Gm. of the salt with 0·5 Gm., each, of iron and of zinc, in coarse powder or filings, be heated with 5 C.c. of potassium hydrate test-solution, no evolution of *ammonia* should be perceptible either by moistened red litmus paper or by odor (absence of *nitrate* or *nitrite*)." *U. S.* "In colorless monoclinic crystals with a cool saline taste, soluble in 16 parts of cold and 3 parts of boiling *water*. Moistened with *hydrochloric acid* it evolves a yellow gas consisting of a mixture of chlorine and chloric oxide. When heated it fuses, gives off oxygen gas, and leaves a white residue soluble in *water*, forming a solution which affords the reactions characteristic of potassium and of chlorides." *Br.* Potassium chlorate is characterized also by becoming first yellow and then red by admixture with a little sulphuric acid, and by the action of that acid evolving chlorine tetroxide (Cl_2O_4), known by its yellow color, and its explosive property when heated; by its bleaching power when mixed first with hydrochloric acid and then with water; and by its property of exploding violently when triturated with a small portion of sulphur or phosphorus or kermes mineral. Potassium chlorate consists of one atom of potassium in combination with the chloric acid group. This salt is an excellent test of manganese existing in organic matter. If a small portion of such matter, containing even a trace of manganese, be thrown on the surface of the *pure* melted salt in a test-glass, after the combustion has ceased the cooled saline mass will be found to have a rose or pinkish tint, caused by the formation of potassium permanganate. (*Neues Repert.*, vi. 247.) A similar discoloration of the salt, produced by the use of pure charcoal in the same manner, will evince the presence of manganese in the chlorate as an impurity.

Medical Properties. Owing to the assertion of Dr. O'Shaughnessy that under the use of potassium chlorate all the blood of the body becomes florid, it was long supposed that the salt acts upon the system as an oxidizing agent. Dr. Isambert, however, has found the statement of O'Shaughnessy incorrect, and as the chlorate does not naturally part with its oxygen at the temperature of the body, and as it is eliminated from the kidneys unchanged, it is evident that it has not the specific action claimed for it. It is more irritant than most of the other salts of potash, and probably acts less powerfully as a cardiac depressant than do most

of them. It is a very efficient remedy in the *follicular* and even the *gangrenous stomatitis* of childhood, and in *mercurial ptyalism*, acting, however, only by its local influence, it being continually eliminated with the saliva and coming in perpetual contact with the mucous membrane of the mouth. It is much employed in *scarlatina* and *diphtheria*, but has no specific action in these affections, being useful only by its direct influence upon the mucous membrane affected. In *scurvy*, *phthisis*, and the various *dyscrasiæ* in which it was once employed, it is of no service.

As an alterative stimulant local application, potassium chlorate is often very useful in inflammations of mucous membranes, such as *stomatitis*, *pharyngitis*, *urethritis*, *vaginitis*, *chronic cystitis*, etc., as well as in indolent *ulcers* either upon the surface of the body or in such interior portions as can be reached. Its saturated solution given by injection with laudanum twice daily is an excellent remedy for *hemorrhoids*. The internal dose is from ten to twenty grains (0·7–1·3 Gm.) every three or four hours, given in sufficient gum water, sweetened water, or lemonade to dissolve it. When administered as a prophylactic in salivation, a smaller dose will answer. Taken to the extent of five drachms (19·4 Gm.) in twenty-four hours, it has been found to produce diuresis, abundant salivation, and a strong saltish taste. Such an amount as this is, however, dangerous even for the adult. When used as a wash or an injection, from a drachm to half an ounce (3·9–15·5 Gm.) of the salt may be dissolved in a pint (472 C.c.) of water. A solution in glycerin, in the proportion of one part of the salt to ten parts of the menstruum, has been especially recommended as a dressing for *ill-conditioned wounds* and *ulcers*. The remedy has also been applied in the form of very fine powder dusted on the surface.

In overdose potassium chlorate is an active poison, four drachms of it having caused death in the adult. The symptoms produced were violent vomiting, profuse diarrhœa, excessive dyspnœa, great failure of the heart's action, and marked cyanosis. The urine is lessened in quantity, albuminous, often of a dark reddish-brown or blackish color, and containing tube-casts and the débris of blood-corpuscles. In some cases there have been marked nervous symptoms, such as cramps, delirium, coma, etc. The lesions found after death are those of gastro-enteritis and acute nephritis, with alteration in the character of the blood, due to the development in it of methæmoglobin. On account of their irritant action on the kidneys, large doses are especially dangerous in *diphtheria*.

POTASSII CITRAS. U. S., Br. Potassium Citrate.

$K_3C_6H_5O_7.H_2O$; 323·59. (PŌ-TĂS'SĬ-Ī CĪ'TRĂS.) $K_3C_6H_5O_7.H_2O$; 324.

"Potassium Citrate should be kept in well-stoppered bottles." *U. S.* "Potassium Citrate, $C_3H_4.OH.(COOK)_3$, is prepared by the interaction of citric acid and potassium carbonate." *Br.*

Kali Citricum, Citras Potassicus, s. Kalicus; Citrate of Potash; Citrate de Potasse, *Fr.*; Citronsaures Kali, *G.*

Potassium citrate was known formerly by the name of *salt of Riverius*. In the U. S. formula of 1870,* mutually saturating proportions of the acid and bicarbonate were intended to be employed, the latter ingredient being preferred to the carbonate on account of its greater purity. The potassium of the bicarbonate unites with the citric acid to form the potassium citrate, and the carbonic acid escapes, producing effervescence. The resulting solution is directed to be evaporated to dryness, as affording the most convenient form for use. The granulation ordered has a tendency to retard the deliquescence of the citrate. The British 1885 process differed only in the use of the carbonate instead of the bicarbonate, and in providing more carefully for an exact neutralization.

Properties. Potassium citrate is crystallizable, but, as usually seen, is in the form of a granular powder. The U. S. P. 1890 recognizes both forms, and describes it as in "transparent, prismatic crystals, or a white, granular powder, odorless, and having a cooling, saline taste. Deliquescent on exposure to air. Soluble in 0·6 part of water at 15° C. (59° F.), and very soluble in boiling water; sparingly soluble in alcohol. When heated above 100° C. (212° F.), the salt begins to lose water; at 200° C. (392° F.) the water of crystallization (5·55 per cent.) is completely lost. At 230° C. (446° F.) the salt begins to decompose, turns brown, and at a higher temperature carbonizes and emits inflammable gases which have a very pungent, acid odor. At a red heat a blackened mass of potassium carbonate and carbon is left, which has an alkaline reaction, and strongly effervesces with acids. The aqueous solution of the salt is neutral to litmus paper. The salt yields a white, crystalline precipitate with sodium

*"Take of Citric Acid *ten troyounces;* Bicarbonate of Potassium *fourteen troyounces;* Water *a sufficient quantity.* Dissolve the Citric Acid in a pint of water, add the Bicarbonate of Potassium gradually, and, when effervescence has ceased, filter the solution and evaporate to dryness, stirring constantly, after a pellicle has begun to form, until the salt granulates. Keep it in a well-stopped bottle." *U. S.*

bitartrate test-solution. With sodium cobaltic nitrite test-solution a yellow precipitate is formed. On mixing 10 C.c. of the aqueous solution (1 in 20) with 2·5 C.c. of calcium chloride test-solution, the liquid remains clear until it is boiled, when a white, granular precipitate is produced. The aqueous solution (1 in 20) should not be colored red by a drop of phenolphtalein test-solution, nor effervesce on the addition of an acid (absence of *carbonate*). Separate portions of this solution acidulated with nitric acid should not be affected by barium chloride test-solution (absence of *sulphate*), nor by silver nitrate test-solution (absence of *chloride*). A solution of 1 Gm. of Potassium Citrate in 1 C.c. of water should not deposit any precipitate on the addition of 1 C.c. of acetic acid (absence of *tartrate*). If 1·08 (1·079) Gm. of Potassium Citrate be thoroughly ignited at a red heat, it should require for complete neutralization not less than 10 C.c. of normal sulphuric acid (corresponding to 100 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* The British Pharmacopœia gives the following tests of its character. "A white powder of saline feebly acid taste, deliquescent, very soluble in *water*. It affords the reactions characteristic of potassium salts and of citrates. Each gramme of the dry salt, heated to redness till gases cease to be evolved, should leave an alkaline residue, which when treated with *water*, filtered, and well washed, should yield a clear solution requiring for neutralization at least 9·7 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, iron, calcium, magnesium, sodium, carbonates, or tartrates, and only the slightest reactions with the tests for chlorides or sulphates."

As citric acid is tribasic, this salt consists of three atoms of potassium combined with the citric acid radical $C_6H_5O_7$, and with this one mol. of water, its formula being $K_3C_6H_5O_7,H_2O$.*

Medical Properties. Potassium citrate is a grateful refrigerant diaphoretic, and has long been used in the *fevers* of this country, in the extemporaneous forms of neutral mixture and effervescing draught. As these require time and a somewhat careful manipulation in their preparation, it has been found more convenient to keep the potassium citrate ready-made and dissolve it in water when wanted for use. This solution will no doubt produce the essential diaphoretic and refrigerant effects of the neutral mixture or the effervescing draught, but is less agreeable to the stomach and palate, because destitute of the carbonic acid contained in these preparations. Potassium citrate dissolved in an excess of lemon-juice affords the most agreeable method of securing the influence of an alkaline salt of potash upon the system, as in *rheumatism*, the *uric acid diathesis*, etc. It is also a very valuable remedy in the first or dry stage of *acute bronchitis*. The usual dose of the citrate is from twenty to twenty-five grains (1·3–1·565 Gm.). When a decided effect upon the system is desired, as much as an ounce (31·1 Gm.) of it may be given in the twenty-four hours.

POTASSII CITRAS EFFERVESCENS. U. S. Effervescent Potassium Citrate.

(PŌ-TĂS'SI-Ī CĪ'TRĂS ĔF-FĔR-VĔS'CĔNS.)

"Citric Acid, *sixty-three grammes* [or 2 ounces av., 97 grains]; Potassium Bicarbonate, *ninety grammes* [or 3 ounces av., 76 grains]; Sugar, *forty-seven grammes* [or 1 ounce av., 288 grains]. Powder the ingredients separately, and mix them thoroughly in a warm mortar. Dry the resulting, uniform paste rapidly at a temperature not exceeding 120° C. (248° F.), and, when it is perfectly dry, reduce it to a powder of the desired degree of fineness. Keep the product in well-stoppered bottles." *U. S.*

This is a new official effervescent salt: it affords an agreeable mode of administering potassium citrate. (See *Magnesii Citras Effervescens.*) The dose is from one to two teaspoonfuls, in cold water.

POTASSII CYANIDUM. U. S. Potassium Cyanide.

KCN; 65.01. (PŌ-TĂS'SI-Ī CŸ-ĂN'I-DŬM.) KCN; 65.

"Potassium Cyanide should be kept in well-stoppered bottles." *U. S.*

Cyanide of Potassium; Potassii Cyanuretum, *U. S.* 1850; Cyanuret of Potassium; Kalium Cyanatum, Cyanuretum Potassicum, s. Kalicum; Cyanure de Potassium, *Fr.*; Cyankalium, *G.*

* *Sodium and Potassium Citrate.* Mr. T. Push, of Dessau, Germany, has made a complete series of citrates, corresponding to the official tartrates, with a view of finding a stable compound. He ascertained that the double sodium and potassium citrate is an extremely stable compound, even when exposed to the air for a long time. He prepares the salt by dissolving 100 parts of citric acid in water, adding 108 parts of pure potassium carbonate and 221 parts of crystallized sodium carbonate, filtering, evaporating, and crystallizing. The crystals are allowed to drain, and the mother-liquor is further concentrated, until, on cooling, it solidifies to a crystalline mass, which is used in the condition of powder. (*Arch. d. Pharm.*, July, 1877, 47; *N. R.*, Sept. 1877.)

The process of U. S. P. 1870 * is that of F. & E. Rodgers, though generally known under the name of Liebig. It furnishes a large product, a considerable part of which is the impurity potassium cyanate. The reaction takes place between one mol. of potassium ferrocyanide and one of potassium carbonate. The iron is set free, the carbonic acid is evolved, and five mols. of potassium cyanide and one of potassium cyanate are formed. The iron occupies the lower part of the fused liquid; and, if the latter be carefully poured out to solidify, the portion contaminated with the iron may be left behind. The reaction is explained by the following equation: $K_4Fe(CN)_6 + K_2CO_3 = 5KCN + KOCN + CO_2 + Fe$. MM. Fordos and Gélis, in an able paper contained in the *Journal de Pharmacie* for Aug. 1857, have pointed out numerous causes which concur in rendering the salt, as obtained by the use of potassium carbonate, impure. The commercial cyanide, which is obtained by this process, was found by these writers to be very impure, containing only from 36 to 55 per cent. of the pure salt. The potassium cyanate may be readily detected by saturating the product with an acid, which will cause an effervescence of carbonic acid and the generation of a salt of ammonium. According to Dr. Schwarz, it may be freed from potassium cyanate and carbonate by treating the impure cyanide with carbon disulphide, which dissolves it, and may be recovered in great measure by distillation. (*Chem. News*, No. 190, p. 41.)

In the process in which the potassium ferrocyanide is ignited alone (U. S. process 1840), the salt is first deprived of its water of crystallization by exposure to a moderate heat, and then calcined at a red heat for two hours, in order to decompose the ferric cyanide. The reaction which takes place is as follows: $K_4Fe(CN)_6 = 4KCN + FeC_2 + N_2$. The product of the calcination is a black, porous mass, consisting of potassium cyanide, mixed with carbide of iron and charcoal. As the cyanide is very prone to absorb oxygen, especially when hot, whereby it is decomposed, atmospheric air is excluded from the retort while it is cooling, by luting its orifice. When the whole is cold, the black mass is reduced to coarse powder, and exhausted by cold distilled water, which dissolves the potassium cyanide and leaves the carbide of iron and charcoal behind. The filtered liquor, therefore, is an aqueous solution of potassium cyanide, which is obtained in a solid state by a rapid evaporation to dryness. During the evaporation a small portion of the cyanide is decomposed, attended with the evolution of ammonia and the production of potassium formiate. A portion of this salt, therefore, contaminates the cyanide, as obtained by this process; but the quantity is too small to interfere with its medicinal action. The decomposition here referred to takes place between one mol. of potassium cyanide and two of water, and is represented by the following equation: $KCN + (H_2O)_2 = NH_3 + HCOOK$. This decomposition is avoided by exhausting the black mass with boiling alcohol of 60 per cent. (sp. gr. 0·896) instead of with water. The alcoholic solution, by evaporation to a pellicle, lets fall the salt upon cooling, as a crystalline precipitate, perfectly white and pure.

According to the process of the French Codex, which is that of Robiquet, this cyanide is obtained in the dry way, without the use of any solvent. The calcination is performed in a coated stone-ware retort, half filled with the ferrocyanide, to which a tube is attached for collecting the gaseous products. When these cease to be disengaged, the heat is gradually raised to a very high temperature, at which it is kept for a quarter of an hour, after which the tube is closed with luting and the whole left undisturbed until quite cold. When the calcination is thus conducted, the retort, upon being broken, will be found to contain a black matter, covered with a fused layer of pure potassium cyanide, resembling white enamel. This is detached by means of a knife, and immediately transferred to a bottle with an accurately fitting stopper. The black matter, under the name of *black potassium cyanide*, is also kept for medicinal use; but the dose of this cannot be accurately fixed, on account of its containing at different times more or less impurity. According to MM. Fordos and Gélis, the French Codex process should supersede the potassium carbonate process, as it gives a product far purer, and in larger proportion to the materials employed, estimated by the pure product. The same process is preferred by Mr. Donovan, who has modified it by substituting for the stone-ware retort an iron mercury bottle, which, when cold, must be cut in two by a chisel and hammer to get out the product. The same recommendation of iron in preference to stone-ware vessels is made by Fordos

* *Potassium Cyanide.* "Take of Ferrocyanide of Potassium, dried, *eight troyounces;* Pure Carbonate of Potassium, dried, *three troyounces.* Mix the salts intimately, and throw the mixture into a deep iron crucible previously heated to redness. Maintain the temperature until effervescence ceases, and the fused mass concretes, of a pure white color, upon a warm glass rod dipped into it. Then pour out the liquid carefully into a shallow dish to solidify, ceasing to pour before the salt becomes contaminated with the precipitated iron. Break up the mass while yet warm, and keep the pieces in a well-stopped bottle." *U. S.* 1870.

and Gélis, who found that the latter, at the high heat employed, were acted on. The process of Wiggers consists in disengaging hydrocyanic acid from a mixture of potassium ferrocyanide and sulphuric acid and passing it into a cooled receiver containing an alcoholic solution of potassium hydrate. The contents of the receiver ultimately form a solid magma of the cyanide, which is drained, washed several times with strong alcohol, pressed between folds of bibulous paper, and dried as quickly as possible. Potassium cyanide may be formed by passing a current of strongly heated nitrogen over charcoal impregnated with potassium carbonate and heated to a white heat. Potassium cyanide with some sodium cyanide admixture is now made by the Niagara Electro-Chemical Co., who manufacture sodium by Castner's process. The manufacture of this sodium potassium cyanide with the aid of sodium depends upon the fact that when the yellow prussiate of potash is heated with sodium neither oxygen nor alkaline carbonates are introduced, the product being an almost chemically pure mixture of sodium and potassium cyanide. This is sold in large amounts for the cyanide extraction process for gold now coming into extensive use.

Properties. Potassium cyanide is in "white, opaque, amorphous pieces, or a white, granular powder, odorless when perfectly dry, but in moist air exhaling the odor of hydrocyanic acid. The taste is sharp, and somewhat alkaline, but should be ascertained with great care, as *the salt is very poisonous.* In moist air the salt deliquesces. Soluble in about 2 parts of water at 15° C. (59° F.). Boiling water dissolves its own weight of the salt, but rapidly decomposes it. In alcohol it is but sparingly soluble. At a low red heat the salt fuses. Its aqueous solution (1 in 20) has a strongly alkaline reaction, and emits the odor of hydrocyanic acid. With an equal volume of sodium bitartrate test-solution it yields a white, crystalline precipitate. With sodium cobaltic nitrite test-solution a copious yellow precipitate is produced. A few drops of the solution give with silver nitrate test-solution a white precipitate, which is soluble in an excess of the solution of potassium cyanide, also in ammonia water, and in concentrated nitric acid (distinction from *silver chloride*). If 5 C.c. of the solution be shaken with a few drops of ferrous sulphate test-solution, and a slight excess of hydrochloric acid then added, a blue precipitate (Prussian blue) will be produced. The aqueous solution (1 in 20) should not produce more than a slight effervescence on the addition of diluted hydrochloric acid (limit of *carbonate*). After the acid has been added in slight excess, a drop of ferric chloride test-solution should produce neither a blue (absence of *ferrocyanide*) nor a red color (*sulphocyanate*). A solution of 0·65 Gm. of Potassium Cyanide in 12 C.c. of water should require the addition of at least 45 C.c. of silver nitrate decinormal volumetric solution before the precipitate, which at first redissolves on agitation, becomes permanent (each C.c. of the volumetric solution indicating 2 per cent. of the pure salt)." *U. S.* If yellow, it contains iron. Its solution effervesces with acids. The salt and its solution, when exposed to the air, exhale the odor of hydrocyanic acid, and become weaker; but the change takes place slowly. Orfila found that the salt, after fourteen days' exposure, by which it was almost entirely liquefied, still possessed energetic poisonous properties. He thinks, therefore, that the bad effects of opening the containing bottle, in dispensing the medicine, have been exaggerated. Unfortunately, the salt varies in quality independently of the effects of time and exposure. Dr. David Stewart, of Baltimore, examined six samples of this cyanide, on sale, and found them to vary considerably in purity. Besides water, the usual impurities are potassium hydrate, carbonate, cyanate, and formiate. They sometimes amount to half the weight of the cyanide, consisting principally of the carbonate. From the extensive use at present made of potassium cyanide in electro-metallurgy and photography, it is of importance to have a reliable test of its purity. Such a test has been discovered by MM. Fordos and Gélis, founded on the fact that one mol. of iodine rapidly reacts with one of the cyanide, so as to form a colorless compound, consisting of one mol. of potassium iodide and one of cyanogen iodide: $KCN + I_2 = KI + CNI$. Accordingly, a tincture of iodine of known strength is gradually added to an aqueous solution of a given weight of the cyanide to be tested, until it assumes a permanent yellowish tinge; and the amount of iodine expended indicates the proportion of cyanide in the specimen. A necessary preliminary step, before using the tincture, is to add sufficient carbonic acid water to the solution of the cyanide to convert any potassium hydrate or carbonate present into bicarbonate, in which state neither has any action on the iodine. This test is applicable to other cyanogen compounds which are soluble. Mr. Thornton J. Herapath's test for commercial potassium cyanide is a standard solution of copper ammonio-sulphate, the blue color of which is destroyed by a solution of the cyanide. The copper solution is added to one of the cyanide of known strength, until a faint blue coloration is produced; and the richness of the sample in pure

cyanide is in proportion to the quantity of the copper solution required. Applying this test to five samples, Mr. Herapath found the proportion of pure cyanide to vary from 41 to 65 per cent. Potassium cyanide yields with silver nitrate a precipitate of silver cyanide, wholly soluble in ammonia and boiling nitric acid. It consists of one atomic group of cyanogen and one of potassium.

Besides the very extensive use of potassium cyanide in preparing electro-plating solutions for gilding and silvering by electro-deposition, and in photography, large quantities are now consumed in the extraction of gold and silver from the fine residues or "tailings" where amalgamation fails to take up the precious metals. From such solutions of gold in potassium cyanide the metal is thrown out by the action of metallic zinc.

Medical Properties. Potassium cyanide acts precisely like hydrocyanic acid as a poison and as a medicine. (See *Acidum Hydrocyanicum Dilutum.*) Five grains of it have repeatedly taken life, and hydrocyanic acid has been detected in the blood of a person who had been fatally poisoned by the cyanide. (Venghauss, *Arch. der Pharm.*, clii. 138.) The grounds on which this cyanide was proposed as a substitute for hydrocyanic acid by Robiquet and Villermé were its uniformity as a chemical product, and its less liability to undergo decomposition. The dose is the eighth of a grain (0·008 Gm.), dissolved in half a fluidounce of distilled water, to which may be added half a fluidrachm of syrup of lemon, if the prescriber wish to set the hydrocyanic acid free. The spurious cyanide formed by calcining dried muscular flesh with potash consists principally of potassium carbonate, and is but slightly poisonous. (*Orfila.*) A solution of potassium cyanide, made with from one to four grains (0·065–0·26 Gm.) to the fluidounce (30 C.c.) of water, has been recommended in *neuralgic* and other *local pains*, applied by means of pieces of linen. Mr. Guthrie found that a solution of from three to six grains (0·2–0·4 Gm.) to the fluidounce (30 C.c.) of distilled water answered admirably, applied by drops every other day, for removing the olive-colored stains of the conjunctiva caused by silver nitrate.

POTASSII ET SODII TARTRAS. U. S. (Br.) Potassium and Sodium Tartrate. [Rochelle Salt.]

$KNaC_4H_4O_6.4H_2O$; 281·51. (PŌ-TĂS'SI-Ī ĔT SŌ'DI-Ī TĂR'TRĂS.) $KNaC_4H_4O_6 + 4H_2O$; 282.

"Sodium Potassium Tartrate, $(CHOH)_2COONa.COOK,4H_2O$, is prepared by neutralizing Acid Potassium Tartrate with Sodium Carbonate." *Br.*

Soda Tartarata, *Br.;* Sodæ et Potassæ Tartras, *Br.* 1864, *U. S.* 1850; Tartarus Natronatus, *P. G.;* Natro-kali Tartaricum; Tartarated Soda; Sal Polychrestum Seignetti, Tartras Potassicosodicus; Sel de Seignette, Soude Tartarisée, *Fr.;* Seignettesalz, *G.*

This salt cannot be made profitably on the small scale (for U. S. process 1870, see the footnote):* it is a double salt, consisting of a molecule of tartaric acid, $C_4H_4O_6.H_2$, in which one of the basic hydrogen atoms is replaced by potassium and the other by sodium. The theory of its formation is very simple, being merely the replacement of the hydrogen in the potassium bitartrate by the sodium of the sodium carbonate, the carbonic acid of which escapes with effervescence. The quantities of the materials for mutual saturation are 285·45 parts of carbonate and 375·34 of bitartrate, or one mol. of crystallized sodium carbonate to two mols. of the acid tartrate. This gives the ratio of 3 to 3·95. The proportion adopted in the U. S. 1870 and Br. Pharmacopœias is as 3 to 4, which is very near the theoretical quantities. As the salts employed are apt to vary in composition and purity, the carbonate from the presence of more or less water of crystallization, and the bitartrate from containing calcium tartrate, it is perhaps best, after indicating the nearest average proportion, to present the alternative of using the cream of tartar to the point of exact saturation.

Properties. Potassium and sodium tartrate is in the form of "colorless, transparent, rhombic prisms, or a white powder, odorless, and having a cooling, saline taste. The crystals slightly effloresce in dry air. Soluble in 1·4 parts of water at 15° C. (59° F.), and in less than 1 part of boiling water; almost insoluble in alcohol. When heated to 74° C. (165·2° F.), the salt fuses to a colorless liquid, which, at a higher temperature, froths, becomes brown, and gradually carbonizes, while inflammable vapors are emitted, having the odor of burning sugar. Finally a black residue is left, consisting of alkaline carbonate mixed with carbon. The aque-

* "Take of Carbonate of Sodium *twelve troyounces;* Bitartrate of Potassium, in fine powder, *sixteen troyounces;* Boiling Water *five pints.* Dissolve the Carbonate of Sodium in the Water, and gradually add the Bitartrate of Potassium. Filter the solution, and evaporate until a pellicle begins to form; then set it aside to crystallize. Pour off the mother-water, and dry the crystals on bibulous paper. Lastly, evaporate the mother-water, that it may furnish more crystals." *U. S.* 1870.

ous solution of the salt is neutral to litmus paper. A 10 per cent. aqueous solution yields, with an equal volume of acetic acid, a white, crystalline precipitate. With sodium cobaltic nitrite test-solution the solution yields a copious yellow precipitate. With silver nitrate test-solution it produces a white precipitate, which becomes black on boiling. To a non-luminous flame it communicates a yellow color (*sodium*), which, when viewed through a blue glass, appears violet-red (*potassium*). The aqueous solution (1 in 20) should not be rendered turbid by the addition of a small amount of ammonium oxalate test-solution (absence of *calcium*), nor by an equal volume of hydrogen sulphide test-solution, either before or after acidulation with diluted hydrochloric acid (absence of *arsenic*, *lead*, *copper*, etc.). When heated with potassium hydrate test-solution, the solution should not give off the odor of *ammonia*. If 10 C.c. of the solution (1 in 20) be mixed with 1 C.c. of hydrochloric acid, the addition of 1 C.c. of barium chloride test-solution should produce no turbidity (absence of *sulphate*). If 0·36 Gm. of the salt be dissolved in 9 C.c. of water, then 1 C.c. of nitric acid and 0·2 C.c. of silver nitrate decinormal volumetric solution be added, and the mixture filtered, the filtrate should remain clear upon the further addition of silver nitrate volumetric solution (limit of *chloride*). If 1·41 Gm. of Potassium and Sodium Tartrate be completely decomposed by ignition, the alkaline residue should require for complete neutralization not less than 10 C.c. of normal sulphuric acid (corresponding to 100 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* "Trimetric prisms with hemihedral facets; it is entirely soluble in cold *water;* and has a saline taste. It affords the reactions characteristic of potassium, of sodium, and of tartrates. Each gramme, heated to redness till gases cease to be evolved, should leave an alkaline residue, which when treated with *water*, filtered, and well washed, yields a clear solution requiring for exact neutralization at least 7 cubic centimetres of the *volumetric solution of sulphuric acid*." *Br.* As it is sometimes largely adulterated with sodium sulphate (F. Mahla, *A. J. P.*, 1868, 548), it is best to test it with barium chloride. When the salt is exposed to a strong heat, it blackens, and gives out inflammable gases with the odor of burnt sugar; the tartaric acid being destroyed, and a mixture of potassium and sodium carbonates left. It sometimes contains calcium tartrate, which may be removed by solution and crystallization; but when the crystals are large and well defined, it may be assumed to be pure. It is incompatible with most acids, and with all acidulous salts except potassium bitartrate. It is also decomposed by lead acetate and subacetate, and by the soluble calcium and barium salts, unless the solution of the tartrate be considerably diluted. The way in which acids act in decomposing it is by combining with the sodium, and throwing down potassium bitartrate as a crystalline precipitate. This double salt was discovered by Seignette, an apothecary of Rochelle, and hence is frequently called *Seignette's salt*, or *Rochelle salt*.

Potassium and sodium tartrate consists of the tartaric acid group $C_4H_4O_6$, which is dibasic, in combination with one atom of potassium and one of sodium, together with 4 mols. of water.

Medical Properties and Uses. This salt is a mild, cooling purgative, well suited to delicate and irritable stomachs, being among the mildest and least unpalatable of the neutral salts. As it is not incompatible with tartar emetic, it may be associated with that salt in solution. It is an ingredient in the effervescing aperient called Seidlitz powders. (See *Pulvis Effervescens Compositus.*) The dose as a purge is from half an ounce to an ounce (15·5–31·1 Gm.). When given in small and repeated doses it usually does not purge, but is absorbed and renders the urine alkaline. (Millon and Laveran, *Journ. de Pharm.*, 3e sér., vii. 222.)

Potassium and magnesium tartrate, formed by saturating cream of tartar with magnesium carbonate, has been proposed by M. Maillier as a safe, pleasant purgative. (*Journ. de Pharm.*, xiii.)

POTASSII FERROCYANIDUM. U. S. Potassium Ferrocyanide.

$K_4Fe(CN)_6.3H_2O$; 421·76. (PŌ-TĂS'SĬ-Ī FĔR-RŌ-CĪ'ĂN'Ĭ-DŬM.) $K_4Fe(CN)_6 + 3H_2O$; 421·9.

Ferrocyanide of Potassium; Yellow Prussiate of Potash; Kalium Ferrocyanatum, *P. G.;* Kalium Borussicum, Cyanuretum Ferroso-potassicum; Ferrocyanuret of Potassium, Ferroprussiate of Potassa, Prussiate of Potassa; Protocyanure jaune de Fer et de Potassium, Prussiate jaune de Potasse, Ferrocyanure de Potassium, *Fr.;* Cyaneisenkalium, Ferrocyankalium, Gelbes Blutlaugensalz, *G.*

The yellow double potassium and iron cyanide is the salt from which potassium cyanide is obtained by calcination at a low red heat.

Potassium ferrocyanide is prepared on the large scale by heating animal matters, such as dried blood, hoofs, chips of horn, woollen rags, old leather, the refuse of tallow-chandlers called *greaves*, and other substances rich in nitrogen, with the pearlash of commerce and scrap iron, in an egg-shaped iron pot called a shell, ladling out the pasty mass called the *melt*, and, after it

has cooled sufficiently, dissolving it in water, and evaporating the solution so that crystals may form. The melt, while still hot, contains potassium cyanide only, the ferrocyanide being produced solely by the action of the water. The best temperature for making the solution is between 70° C. and 80° C. (158° F. and 176° F.); and the conversion of the cyanide into the ferrocyanide is facilitated by the presence of finely divided amorphous ferrous sulphide, and of caustic potassa. The reactions involved in the formation of the ferrocyanide are supposed to be $K_2CO_3 + 4C + 2N = 2KCN + 3CO$ and $6KCN + FeS = K_2S + K_4Fe(CN)_6$.

It has been sought to increase the yield of the ferrocyanide by avoiding the use of sulphur-containing materials and taking a relatively pure potash and fusing this first with the nitrogen-containing materials, and, after extracting with water from this fusion, to digest the liquors so obtained with ferrous hydrate or carbonate, the reaction being $6KCN + FeCO_3 = K_4Fe(CN)_6 + K_2CO_3$.

Some years ago this salt was manufactured by a process which dispensed with the use of animal matter, the necessary nitrogen being obtained by a current of atmospheric air. Fragments of charcoal, impregnated with 30 per cent. of potassium carbonate, were heated to a white heat in a cylinder through which a current of air was drawn by a suction-pump. This process is understood to have succeeded in a chemical sense, but failed on the score of economy, chiefly from the circumstance that the necessary fire-clay tubes could not be made to resist the combined action of the alkali and heat. The process of Richard Brunnquell consists in passing ammonia through tubes filled with charcoal and heated to redness, so as to form ammonium cyanide, and converting this into potassium ferrocyanide by contact with solution of potash and suitable iron compounds.

Properties. Potassium ferrocyanide is in "large, soft, transparent, yellow, four-sided, monoclinic tables, odorless, and having a mild, saline taste. Slightly efflorescent on exposure to dry air. Soluble in 4 parts of water at 15° C. (59° F.), and in 2 parts of boiling water; insoluble in alcohol. When heated to 60° C. (140° F.), the salt begins to turn white from loss of water, and when heated to 100° C. (212° F.), it is rendered anhydrous. The aqueous solution is neutral to litmus paper. With sodium bitartrate test-solution the aqueous solution yields a white, crystalline precipitate. Sodium cobaltic nitrite test-solution produces a copious yellow precipitate. The color of the precipitate produced by ferric chloride test-solution is dark blue; that produced by copper sulphate test-solution is reddish-brown; while lead acetate test-solution or silver nitrate test-solution throws down a pure white precipitate. No effervescence should be caused by the addition of diluted sulphuric acid to a concentrated solution of the salt (absence of *carbonate*). The aqueous solution (1 in 20), acidulated with hydrochloric acid, should, upon the addition of barium chloride test-solution, remain clear, or at most show but a trifling turbidity (limit of *sulphate*). If a mixture of 0·5 Gm. of the salt with 1·5 Gm. of pure potassium nitrate and 0·5 Gm. of pure, anhydrous sodium carbonate be heated to redness in a porcelain crucible, the residue dissolved in water, the filtered solution supersaturated with nitric acid, mixed with 0·1 C.c. of silver nitrate decinormal volumetric solution, and again filtered, no turbidity should be produced in the filtrate by the further addition of silver nitrate volumetric solution (limit of *chloride*). The precipitate produced in the aqueous solution, acidulated with nitric acid, by silver nitrate test-solution should be of a pure white color, without a tinge of red (absence of *ferricyanide*)." *U. S.* It acts but slightly, if at all, on turmeric paper. The alkaline reaction, when it exists, is probably owing to the presence of a little free potassa. When ignited, the insoluble residue amounts to 18·7 per cent. of ferric oxide, resulting from the oxidation of the iron of the salt. It is characterized by striking a deep-blue color with ferric salts,* a deep-brown one with the salts of copper, and a white one with those of zinc, the

* *Ferri Ferrocyanidum*, U. S. 1870. *Ferri Ferrocyanuretum*, U. S. 1850. *Ferrocyanide of Iron. Ferrocyanuret of Iron. Pure Prussian Blue.* "Take of Ferrocyanide of Potassium *nine troyounces;* Solution of Tersulphate of Iron *a pint;* Water *three pints.* Dissolve the Ferrocyanide of Potassium in two pints of the Water, and add the solution gradually to the Solution of Tersulphate of Iron, previously diluted with the remainder of the Water, stirring the mixture during the addition. Then filter the liquid, and wash the precipitate on the filter with boiling water until the washings pass nearly tasteless. Lastly, dry it, and rub it into a powder." *U. S.* 1870.

In the above process the salt is decomposed by the gradual addition of the solution of potassium ferrocyanide. Three mols. of ferrocyanide and two of ferric sulphate are mutually decomposed, with the result of forming one mol. of Prussian blue, or the 3–4 ferric ferrocyanide, which precipitates, and six mols. of potassium sulphate, which remain in solution, the reaction being $(FeK_4(CN)_6)_3 + 2Fe_2(SO_4)_3 = Fe_3Fe_4(CN)_{18} + 6K_2SO_4$.

Preparation for Use in the Arts. Prussian blue is manufactured on the large scale as follows. A mixture made of equal parts of potassium carbonate (pearlash of commerce) and of animal matter, such as dried blood, hair, the shavings of horn, etc., is calcined at a red heat, in an iron vessel, until it becomes pasty. The mass, when cold, is thrown, by portions at a time, into twelve or fifteen times its weight of water, with which it is stirred for half an hour. The whole is then put upon a linen filter, and the clear solution obtained is precipitated by a mixed solution

several precipitates formed being ferrocyanides of the respective metals. Heated with eight or ten times its weight of concentrated sulphuric acid, it evolves carbonic oxide. Half an ounce of the salt yields about 250 cubic inches of the gas. (*C. Grimm and G. Ramdohr.*) When boiled with dilute sulphuric acid, it emits the smell of hydrocyanic acid. Potassium ferrocyanide consists of six groups of the monad radical cyanogen (CN), saturated by four potassium atoms and one atom of the dyad iron. The potassium is more readily displaced than the iron, so that it is considered as the potassium salt of an acid called *ferrocyanic*. This acid in the free state would be $H_4Fe(CN)_6$. The salt is remarkably pure as it occurs in commerce.

Medical Properties. Pure potassium ferrocyanide is physiologically very inactive. Thus, Combemale and Dubiquet proved that in doses of twelve grains to the pound of bodily weight it is not poisonous to the lower animals, whilst Callies, as quoted by Pereira, found the commercial salt slightly poisonous, but the pure salt unproductive of harm in the dose of several ounces. It should be borne in mind that it is the commercial salt which is used medicinally. Westrumb and Hering proved that it passed with rapidity into the blood and urine. Many years ago, Dr. B. Smart (*Amer. Journ. of Med. Sci.*, xv. 362) attributed sedative astringent properties to this drug, and asserted that it is a valuable remedy against the *colliquative sweats* of phthisis. The form of administration which Dr. Smart preferred was that of solution, in the proportion of two drachms to the fluidounce (7·8 Gm.–30 C.c.) of water. Of this the dose for an adult is from 30 to 45 drops (1·9–2·8 C.c.), equivalent to from 10 to 15 grains (0·65–0·97 Gm.) of the salt, repeated every four or six hours.

This salt is manufactured on a large scale, chiefly for the use of dyers and calico-printers. In pharmacy it is employed to prepare diluted hydrocyanic acid, Prussian blue, and potassium and silver cyanides.

POTASSII HYPOPHOSPHIS. U. S. Potassium Hypophosphite.

KH_2PO_2; 103·91. (PŌ-TĂS′SĪ-Ī HĪ-PŌ-PHŎS′PHĪS.) KH_2PO_2; 104.

"Potassium Hypophosphite should be kept in well-stoppered bottles." *U. S.*

Kali Hypophosphorosum, Hypophosphis Potassicus, s. Kalicus; Hypophosphite de Potasse, *Fr.;* Unterphosphorigsaures Kali, *G.*

This salt is prepared by mixing solutions of calcium hypophosphite and granulated potassium carbonate, in the proportion of six ounces of the former dissolved in four pints of water to 5·75 ounces of the latter in half a pint. As a result of double decomposition between the

of two parts of alum and one of ferrous sulphate. An effervescence occurs, due principally to carbonic acid; and a very abundant precipitate is thrown down of a blackish-brown color. This precipitate is washed, by decantation, by means of a large quantity of water, which is removed every twelve hours. By these washings, which last from twenty to twenty-five days, the precipitate becomes successively greenish brown, bluish, and finally deep blue. When of the latter color, it is collected and allowed to drain upon a cloth, after which it is divided into cubical masses and dried.

A preparation under the name of *Soluble Prussian Blue* has been introduced into use for injecting anatomical preparations by Schroeder van der Kolk, and is said to be much esteemed for this purpose. To obtain it there must be a great excess of the potassium ferrocyanide in concentrated solution. The iron should be in a state of sesquichloride, in the proportion of not more than one-eighth or one-tenth of the ferrocyanide employed. After their mixture, the precipitate is washed with water till it begins to become blue, when it is expressed and dried in the air. On the small scale it may be economically obtained in the following manner. Take solutions of the ferrocyanide containing 217 grammes to the liter of water, and of the sesquichloride containing one part of the solid salt in 10 parts of water. Then, taking equal volumes of the two solutions, add to each one twice its volume of a cold concentrated solution of sodium sulphate, and mix the solutions. Put on a filter, and treat as directed above. The product dried in the air is perfectly soluble, and admirably adapted for injection. (*Journ. de Pharm.*, 4e sér., iv. 238.) For other formulæ for Soluble Prussian Blue, see *Ibid.*, 4e sér., xix. 227.

Properties. Pure Prussian blue is a tasteless powder, insoluble in water and alcohol, and having a rich deep-blue color. It is insoluble in dilute acids, decomposed by fuming nitric acid, and dissolved without decomposition by strong sulphuric acid, forming a white mass of the consistence of paste, from which the Prussian blue may be precipitated unchanged by water. Concentrated hydrochloric acid decomposes it, dissolving ferric oxide, and liberating hydroferrocyanic acid (H_2Cfy). Boiled with mercuric oxide, it generates mercuric cyanide. (See *Hydrargyri Cyanidum.*) By the contact of a red-hot body it takes fire and burns slowly, leaving a residue of ferric oxide. When it is heated in close vessels, water, hydrocyanic acid, and ammonium carbonate are evolved, and iron carbide is left. Its composition has been given above. The Prussian blue of commerce was discovered by accident, in 1710, by Diesbach, a preparer of colors at Berlin. It has the same general properties as the pure substance. It occurs in small rectangular masses, which are heavier than water and have a fracture presenting a bronzed appearance. Besides the constituents of pure Prussian blue, it always contains uncombined ferric oxide, and a portion of alumina, derived from the alum employed in its manufacture, which serves to give it body as a pigment. These substances may be detected by boiling the pigment with dilute hydrochloric acid and precipitating the filtered solution with ammonia. Pure Prussian blue treated in this manner yields no precipitate.

Medical Properties. Prussian blue has been deemed tonic, febrifuge, and alterative, but is at present very rarely used, and is probably of no medicinal value. It is sometimes employed as an application to ill-conditioned *ulcers*, mixed with simple ointment in the proportion of a drachm to the ounce. The dose is from three to five grains (0·20–0·33 Gm.), repeated several times a day, and gradually increased until some effect is produced.

two salts, calcium carbonate and potassium hypophosphite are formed, the former being precipitated, and the latter held in solution. The calcium carbonate is removed by filtration, and the clear solution is evaporated till a pellicle forms, after which it is constantly stirred, with continuance of the heat, until the salt granulates. The heat employed in the evaporation should be kept considerably below 100° C. (212° F.), for fear of explosion. If the salt be required quite pure, it should be dissolved in the granulated state, in official alcohol, and the solution evaporated to a syrupy consistence and then set aside to crystallize. The calcium hypophosphite may be prepared by a formula given under the head of Calcium Hypophosphite.

Properties. Potassium hypophosphite, according to the Pharmacopœia, is in "white, opaque, hexagonal plates, or crystalline masses, or a granular powder, odorless, and having a pungent, saline taste; very deliquescent. Soluble, at 15° C. (59° F.), in 0·6 part of water, and in 7·3 parts of alcohol; in 0·3 part of boiling water, and in 3·6 parts of boiling alcohol; insoluble in ether. When heated in a dry test-tube, the salt at first loses moisture, and then evolves spontaneously inflammable hydrogen phosphide gas, which burns with a bright yellow flame. On triturating or heating the salt with nitrates, chlorates, or other oxidizing agents, it detonates violently. The aqueous solution (1 in 20) is neutral to litmus paper, and yields, with sodium bitartrate test-solution, a white, crystalline precipitate. With silver nitrate test-solution a white precipitate is formed, which rapidly turns brown and black, owing to the separation of metallic silver. If a small quantity of an aqueous solution of the salt be acidulated with hydrochloric acid, and mercuric chloride test-solution added, so that the latter remain in excess, a white precipitate of mercurous chloride will at first be produced, which, upon further addition of the acidulated solution, is reduced to metallic mercury. The aqueous solution of the salt (1 in 20) should not effervesce on the addition of an acid (absence of *carbonate*); nor should it be rendered turbid by ammonium oxalate test-solution (absence of *calcium*). Separate portions of 5 C.c. of the aqueous solution (1 in 20), heated with 1 C.c. of nitric acid, should remain clear upon the addition of silver nitrate test-solution (absence of *chloride*), or of barium chloride test-solution (absence of *sulphate*). Not more than a slight cloudiness should be produced in the aqueous solution of the salt by the addition of magnesia mixture (limit of *phosphate*). If 0·1 Gm. of dry Potassium Hypophosphite be dissolved in 10 C.c. of water, then mixed with 7·5 C.c. of sulphuric acid and 40 C.c. of potassium permanganate decinormal volumetric solution, and the mixture be boiled for fifteen minutes, it should not require more than 2 C.c. of oxalic acid decinormal volumetric solution to discharge the red color (corresponding to at least 98·7 per cent. of the pure salt)." *U. S.*

Medical Properties and Uses. This salt, and several other *hypophosphites*, as those of calcium, sodium, ammonium, etc., were brought into notice a few years since, in consequence of their supposed efficiency in the introduction of phosphorus into the system in cases in which this element might be thought to be deficient. Upon this principle they were recommended by Dr. Churchill, of Paris, in the treatment of *phthisis*, and came into extensive employment; but experience has hardly confirmed the first favorable impression of their usefulness in this complaint. There seem, however, to be good grounds for their application to *diseases attended with deficiency of nerve-power* from debility of the brain, and in certain *scrofulous affections* of children, especially those connected with a disordered condition of the bones. The dose of potassium hypophosphite is for adults from ten to thirty grains (0·65–1·95 Gm.) three times a day, and may be given dissolved in water, or in the form of syrup.

POTASSII IODIDUM. U. S., Br. Potassium Iodide.

KI; 165·56. (PŌ-TĂS'SĬ-Ī Ī-ŌD'Ĭ-DŬM.) KI; 165·6.

"Potassium Iodide should be kept in well-stoppered bottles." *U. S.* "Potassium Iodide, KI, may be prepared in the same manner as Potassium Bromide, iodine being used in place of bromine." *Br.*

Iodide of Potassium; Potassii Hydriodas; Kalium Iodatum, *P. G.;* Kali Hydriodicum, Ioduretum Potassicum, s. Kalicum; Iodure de Potassium, *Fr.;* Jodkalium, *G.*

No process is given in the U. S. or Br. Pharmacopœias. That of the U. S. P. 1870 did not differ essentially from the British 1885.*

* "Take of Solution of Potash *one gallon* [Imperial measure]; Iodine *twenty-one ounces* [avoirdupois], or *a sufficiency;* Wood Charcoal, in fine powder, *three ounces* [av.]; Boiling Distilled Water *a sufficiency.* Put the Solution of Potash into a glass or porcelain vessel, and add the Iodine in small quantities at a time, with constant agitation, until the solution acquires a permanent brown tint. Evaporate the whole to dryness in a porcelain dish, pulverize the residue, and mix this intimately with the Charcoal. Throw the mixture, in small quantities at a time, into a red-hot iron crucible, and, when the whole has been brought to a state of fusion, remove the crucible from the fire and

An aqueous solution of potassa is treated with iodine in slight excess. The result of thus saturating potassa with iodine is the formation of two salts, potassium iodide and iodate. Six atoms of iodine react with six mols. of potassa, and there are formed five mols. of potassium iodide and one of potassium iodate, $6KOH + (I_2)_3 = 5KI + KIO_3 + 3H_2O$. By evaporating the solution to dryness the mixed salts are obtained; and, if the dry mass be exposed to a red heat, the iodate will be converted into iodide, thus removing this impurity from the iodide. In the formula the mixed salts, towards the close of their evaporation to dryness, are directed to be mixed with powdered charcoal, according to the plan of Mr. Scanlan, which facilitates the deoxidation of the iodate. This being accomplished by a dull red heat, the potassium iodide is dissolved out of the mass, and the solution is set aside to crystallize.

In the old Edin. and Dublin processes the first step was to form ferrous iodide in solution, precisely as is done in the formula for that compound; and the second to decompose it by potassium carbonate, which gave rise to potassium iodide in solution, and a precipitate of ferrous carbonate. The solution of potassium iodide was separated by filtration and washing from the precipitated carbonate, and evaporated to dryness. The dry salt was then freed from iron and other impurities by solution in boiling water or alcohol, filtration, and crystallization. Messrs. T. and H. Smith, of Edinburgh, instead of washing the precipitate, prefer the plan of pressing it strongly in a cloth, in order to extract the remains of the solution. The mass left is broken up in a portion of distilled water equal to about two-thirds of the weight of the iodine employed, and pressed a second time. Proceeding thus, less water is used, and less evaporation is necessary. The solution obtained by them is evaporated to dryness, and the dry salt is carefully fused in an iron pot, in order to free it from color. It is then dissolved, and the solution, by filtration, concentration, and cooling, furnishes a perfectly pure iodide nearly to the last. According to the method of E. Sonstadt, potassium iodide is prepared directly from the mother-liquors of kelp by converting the alkaline iodides into iodates by means of chlorine or potassium permanganate, precipitating the iodic acid by a soluble barium salt, heating the precipitate with solution of potassium sulphate, evaporating and melting the resulting potassium iodate solution, and crystallizing its solution from the potassium iodide thus obtained. (*Chem. News*. xxvi. 182.) Or, these mother-liquors are evaporated to dryness, the mass gently roasted to oxidize sulphides, and then extracted with water, evaporated again to dryness and extracted with alcohol, whereby sodium and potassium iodide go into solution. This is treated with potassium carbonate to change the sodium iodide into potassium iodide, and a stream of CO_2 led through to precipitate the sodium bicarbonate. The remaining solution contains potassium iodide with a little sodium bicarbonate. (Flückiger, *Pharm. Chem.*, 2d ed., 1888, p. 341.) Large quantities are now manufactured from the cuprous iodide coming from the South American sodium nitrate works. The cuprous iodide is suspended in water acidified with hydrochloric acid, and a stream of hydrogen sulphide gas led in, whereby hydrogen iodide enters into solution. This solution is filtered, neutralized with potassium carbonate, and evaporated to crystallization.

Properties. Potassium iodide, sometimes incorrectly called *hydriodate of potassa*, is in "colorless, transparent or translucent, cubical crystals (the white, opaque, commercial variety being crystallized from an alkaline solution, and less pure), or a white, granular powder, having a peculiar, faint, iodine-like odor, and a pungent, saline, afterwards bitter taste. Permanent in dry air, and but slightly deliquescent in moist air. Soluble, at 15° C. (59° F.), in 0·75 part of water, and in 18 parts of alcohol; in 0·5 part of boiling water, and in 6 parts of boiling alcohol; also soluble in 2·5 parts of glycerin. When heated, the salt decrepitates. At a low red heat it fuses, and at a bright red heat it is volatilized without decomposition. Its aqueous solution is neutral, or has, at most, a scarcely perceptible alkaline reaction upon litmus paper. The salt yields a white, crystalline precipitate with sodium bitartrate test-solution. If to 5 C.c. of the aqueous solution (1 in 20) of the salt 1 C.c. of chlorine water be added, iodine will be liberated, and impart to the solution a yellow color. On agitating the mixture with a few drops of chloroform, this will acquire a violet color." *U. S.* According to the Messrs. Smith, of Edinburgh, it is not at all deliquescent when perfectly pure. It generally crystallizes in cubes. If solution of potassium iodide be mixed with solution of starch, and a minute solution of chlorine be added, a blue color will be produced, the chlorine combining with the potassium and thus liberating the iodine, which forms a blue compound with starch. Its solution is decomposed

pour out its contents. When the fused mass has cooled, dissolve it in two pints [Imp. meas.] of boiling distilled water, filter through paper, wash the filter with a little boiling distilled water, unite the liquids, and evaporate the whole till a film forms on the surface. Set it aside to cool and crystallize. Drain the crystals, and dry them quickly in a warm place. More crystals may be obtained by evaporating the mother-liquor and cooling. The salt should be kept in a stoppered bottle." *Br.* 1885.

by the addition of a few drops of sulphuric acid, hydriodic acid being generated, which speedily undergoes decomposition, with evolution of iodine; and, if starch be added after the lapse of a few minutes, a blue color will be produced. The starch test will not give the characteristic blue color immediately, if added simultaneously with the acid, unless the potassium iodide contains potassium iodate, which impurity causes an immediate liberation of iodine. The blue color being produced by the starch and acid, if simultaneously added, is, therefore, a sign of impurity. A very delicate test for potassium iodide and other soluble iodides is that of M. Grange. It consists in pouring a little of the liquid to be examined into a test-tube, adding a few drops of solution of starch, and passing through the mixture a few bubbles of fuming nitrous acid. The liquid immediately assumes a pale rose color, inclining to violet, if containing 1-200,000th of its weight of the iodide, and a bright blue color if 1-100,000th is present. (See page 746.) When tartaric acid is freely added to a strong solution of the iodide, it occasions a white crystalline precipitate, and the supernatant liquid, if mixed with starch, becomes first purple, and finally blue. Platinic chloride colors its solution reddish brown, without causing a precipitate; barium chloride but slightly affects it; and ferrous sulphate occasions no change. The non-action of the last test shows the absence of potassium carbonate. The aqueous solution is capable of taking up a large quantity of iodine, forming a liquid of a deep-brown color.

M. Payen has noticed a curious effect produced by potassium iodide. In saturated solution, this salt causes in starch added to it an enlargement of its granules to twenty-five or thirty times their original volume, dissolving the interior substance of the granules, and enormously distending the exterior layer. Potassium bromide produces the same effect; but the alkaline chlorides cause neither the enlargement referred to, nor a solution of the amylaceous substance; and if the saturated solution of the iodide be diluted with three and a half volumes of water or more, it is inert in reference to starch in the cold. (*Journ. de Pharm.*, 4e sér., ii. 373.) M. Ferières found that ether added to a solution of potassium iodide decomposes it, but it has been shown by the researches of M. de Vrij and of M. Magnes-Lahens that this does not happen with pure ether, but is due to the acetic acid which is developed by sunlight in ether. (*Journ. de Pharm.*, 4e sér., xvi. 107, 468; xvii. 116.)

Tests. Exposed to a dull red heat, potassium iodide fuses, and on cooling concretes into a crystalline pearly mass, without loss of weight; but at a full red heat it is slowly volatilized without decomposition. The most usual impurities contained in this salt are potassium and sodium chlorides, potassium bromide, and potassium carbonate and iodate. According to M. Payen, the potassium iodide of commerce generally contains potassium carbonate and iodine in excess. (*Journ. de Pharm.*, 4e sér., ii. 373.) He states, however, that it may be easily purified by saturating the potassa with hydriodic acid, and then eliminating the excess of iodine by hydrogen sulphide, boiling, rest, and filtration. (*Ibid.*, p. 368.) The presence of a chloride may be determined by silver nitrate. This test will throw down nothing from the pure salt but silver iodide, which is scarcely soluble in ammonia, while silver chloride is readily soluble in it. If then a solution of the iodide be precipitated by an excess of silver nitrate, and treated with ammonia, the latter will dissolve any chloride which may have been thrown down, and will yield it again as a white precipitate on being saturated with nitric acid. If, on the other hand, the potassium iodide be pure, the ammonia will take up only a minute quantity of silver iodide, and the addition of nitric acid will scarcely disturb the transparency of the solution. The silver iodide precipitated from 10 grains of potassium iodide weighs, when washed and dried, 14·1 grains. When lead acetate is added to a solution of potassium iodide, a yellow precipitate of lead iodide is thrown down, soluble in boiling water. Potassium iodide, to conform to the U. S. P. 1890, must contain 99·5 per cent. of the pure salt. The official tests are as follows: "No residue should be left when 1 Gm. of the salt is dissolved in 2 C.c. of diluted alcohol of specific gravity 0·928 (absence of *less soluble salts*). If 1 Gm. of the salt be dissolved in water and 0·05 C.c. (one drop) of oxalic acid decinormal volumetric solution be added, no color should be produced by the subsequent addition of a drop of phenolphtalein test-solution, even after heating (limit of *alkali*). When a fragment of the salt is brought into a non-luminous flame on a clean platinum wire, a violet color should appear at once (absence of *sodium*). If to a solution of the salt (1 in 20) in distilled water, from which all gases have been expelled by boiling, a little starch test-solution be added, and then a few drops of pure diluted sulphuric acid test-solution, no blue color should appear at once (absence of *iodate*). The aqueous solution (1 in 20) should not be colored or precipitated by the addition of an equal volume of hydrogen sulphide test-solution, either before or after acidulation with hydrochloric acid (absence of *arsenic, lead, copper*, etc.). The aqueous solution should remain

clear after the addition of barium chloride test solution (absence of *sulphate*). If 1 Gm. of the salt be mixed with 0·5 Gm., each, of iron and of zinc, in coarse powder or filings, and heated in a test-tube with 5 C.c. of sodium hydrate test-solution, no ammoniacal vapors should be evolved (absence of *nitrate* or *nitrite*). No blue color should be communicated to 5 C.c. of the aqueous solution (1 in 20) by 0·1 C.c. (2 drops) of potassium ferrocyanide test-solution (absence of *iron*). If 5 C.c. of the aqueous solution be gently heated with 1 drop of ferrous sulphate test-solution and 0·5 C.c. of potassium hydrate test-solution, no blue color should appear after acidulating the mixture with hydrochloric acid (absence of *cyanide*). If 0·5 Gm. of the well-dried salt be dissolved in 10 C.c. of water, and 2 drops of potassium chromate test-solution be added, it should require not more than 30·25 C.c. nor less than 30 C.c. of silver nitrate decinormal volumetric solution to produce a permanent red color of silver chromate (corresponding to at least 99·5 per cent. of the pure salt)." *U. S.* "Each gramme should require for complete precipitation not less than 59·5 and not more than 61·9 cubic centimetres of the *volumetric solution of silver nitrate*." *Br.* The low price of potassium bromide, compared with that of the iodide, has caused the former to be used to adulterate the latter. When potassium bromide is sold for the iodide, the fraud may be detected by the fact that the addition of sulphuric acid produces copious reddish fumes, instead of the purple ones arising from the iodide. A very delicate test for bromide in iodide is based upon the different actions of iodide and bromide with lead peroxide. This reagent will liberate iodine from iodide on boiling, but will not decompose any bromide by boiling. Therefore, after the suspected sample has been boiled with the lead peroxide until all the iodine is driven off, and then filtered, the filtrate may be treated with fresh peroxide and a little acetic acid, when any bromine present is decomposed, and the free bromine will color carbon disulphide or answer other tests. (Flückiger, *Pharm. Chem.*, 2d ed., 1888, p. 350.) M. Lepage determines the amount of the bromide as follows. Dissolve one gramme of corrosive sublimate in twenty cubic centimeters of water; also one gramme of the suspected iodide in thirty grammes of pure water. Add by means of a burette the former fluid to the latter until it just ceases to cause a turbidity. If the iodide is pure, at least 16 C.c. of the mercurial solution are required; if impure, the remaining solution will exceed the volume of 4 C.c. in proportion as the potassium iodide has been replaced by bromide. For this test it is necessary that the iodide be free from chloride, carbonate, and iodate. (*A. J. P.*, xliv. 167.) In order to detect bromine, M. Personne first precipitates from an aqueous solution of the suspected iodide the whole of the iodine as cuprous iodide, by successively adding, in excess, a solution of copper sulphate and aqueous sulphurous acid, and then treats the filtered liquid with ether and chlorine water, the whole being shaken together and left at rest. If bromine be present, the ether which rises to the surface will be tinged of a reddish-yellow color. Fresenius's test of gold chloride is, according to Dr. J. H. Bill, of the U. S. Army, very delicate. The iodine having been separated by palladium, and the excess of palladium by hydrogen sulphide, the solution supposed to contain bromine, if treated first with a drop of hydrochloric acid, and then with a drop of solution of gold chloride, will, if bromine be present, exhibit a decided yellowness, which will appear more obviously if the solution be compared with pure water or a weak solution of a chloride. (See *A. J. P.*, May, 1868, 272.) Potassium carbonate may be discovered by lime water, which causes a milkiness (calcium carbonate), and by tincture of iodine, the color of which is destroyed. The iodate may be detected by adding a solution of tartaric acid to a solution of the suspected iodide. Potassium bitartrate will be precipitated, and, if the iodide be pure, a yellow color will *soon* be developed by the action of the air on the liberated hydriodic acid; but if any iodate be present the test will give rise to both iodic and hydriodic acids, which, by their mutual action, will *instantly* develop iodine.

Mr. William Copney has pointed out an excellent test for detecting potassium carbonate and iodate, in the use of ferrous iodide, in the form of syrup of ferrous iodide, recently prepared. (See *Syrupus Ferri Iodidi*.) A drop of the syrup is added to a solution of the suspected potassium iodide. A bluish precipitate indicates the carbonate; a red one, the iodate; and a blue precipitate, followed by a red one, both impurities. Potassium carbonate is generally present in the proportion of from 1 to 10 per cent. Dr. Christison has detected 74½ per cent., and Dr. Pereira as high as 77 per cent. An adulteration by the carbonate under 10 per cent. does not alter the crystalline appearance of the iodide, but gives it an increased tendency to deliquesce. When it is greater it renders the salt granular and highly deliquescent. As potassium iodide is soluble in rectified spirit, anything left undissolved by that solvent is impurity. (*A. J. P.*, xxvi. 293.) A seemingly better method is that of M. Personne, founded upon the fact that when mercuric chloride is added to a solution of the iodide in just sufficient

amount to form potassio-mercuric iodide the solution remains clear, but on the further addition of the minutest quantity of the chloride a persistent reddish or rose-colored precipitate is formed. He prepares the titrating solution by dissolving 13·55 grammes of mercuric chloride and 8 to 10 grammes of common salt in 200 to 250 grammes of distilled water, and then adding sufficient distilled water to make the whole measure one liter; 10 cubic centimeters of this correspond to 0·1355 of the chloride. Of the iodide to be tested 3·32 grammes are dissolved in sufficient water to make exactly 100 cubic centimeters. The titration is performed by putting 10 cubic centimeters of this in a beaker glass, and adding from a burette, drop by drop, the mercurial liquid, keeping the beaker in a constant agitation by means of the gyratory movement with the hand. When the red color appears the titration is complete. If the iodide be pure, 10 cubic centimeters of the mercurial solution will have been used; if only 8 C.c. have been used, it is known that the iodide contains only 80 per cent. of the pure salt; 9 C.c. indicate 90 per cent.; 7 C.c., 70 per cent., and so on. The presence of potassium bromide, chloride, or carbonate is said not to interfere with this test. (*Journ. de Pharm.*, Janv. 1875, p. 5.) Potassium iodide contains no water of crystallization.

According to M. Payen, a saturated solution of potassium iodide, which will evince signs of decomposition by becoming orange-yellow, in the presence of atmospheric air, on the addition of small quantities of acetic, nitric, oxalic, and probably many other acids, remains unaffected by these additions if atmospheric air be excluded. The air oxidizes a portion of the potassium, which then unites with the acid, and the iodine liberated gives color to the solution. (*Journ. de Pharm.*, 4e sér., iii. 200.) As first pointed out by M. Loew (*A. J. P.*, xlii. 80), and confirmed by M. Vidau in an elaborate series of experiments, iodine is liberated from a solution of potassium iodide by direct sunlight; the more concentrated the solution the more energetic is the action. (*Journ. de Pharm.*, 4e sér., xx. 351.)

Potassium iodide is incompatible with alkaloids, calomel, mercurous and mercuric oxides, turpeth mineral, white precipitate, blue mass, and metallic mercury. M. Melsens observes that potassium iodide given in connection with the insoluble preparations of mercury renders them soluble and much more active. (See *A. J. P.*, xxvi. 222.) With nitrous ether potassium iodide reacts, yielding, among other products, ethyl iodide and a little ordinary ether. (Juncadella, *Comptes-Rendus*, Fév. 1859, p. 345.) At ordinary temperatures potassium iodide is slowly decomposed, with evolution of iodine, by ammonium nitrate or boric acid, and at high temperatures, in a glass test-tube, with escape of violet vapors, not only by the two substances just named, but also by ammonium sulphate, oxalate, carbonate, and chloride, sodium sulphate, phosphate, nitrate, and borate, potassium and magnesium sulphates, calcium nitrate, sodium, potassium, and calcium chlorides, and silicic acid. (Ubaldini, *Journ. de Pharm.*, Oct. 1859, p. 292.) M. Melsens has noticed another very important fact in relation to the operation of potassium iodide. When this salt and potassium chlorate are mixed in solution, no change takes place at ordinary temperatures; but if a certain amount of a mineral acid be added to the solution of the mixed salts, a reaction occurs, attended with the escape of iodine; and evidences are presented of the existence of iodic acid in the solution. Now, M. Melsens has ascertained by experiments on dogs that neither of these salts, if given separately and at different times, produces an evil effect; while if given together, so as to be in the system at the same time, they act as a poison, and may cause death in a few days. Seven grammes (108 grains) of a mixture of potassium iodide and potassium chlorate, in equivalent proportions, given daily to a dog of medium size, uniformly proved fatal in less than a month, and often as early as the fifth day. M. Melsens ascribed the result to the production of potassium iodate, which he has shown to be a poisonous salt. (*A. J. P.*, Nov. 1866, p. 521; from *Bull. de la Soc. Chim. de Paris.*) With the alkaloids potassium iodide is incompatible, and fatal results have been caused by the strychnine iodide crystallizing out of a prescription, so that the whole of it was taken at a single dose.

Medical Properties. The general therapeutic properties of the preparations of iodine, of which potassium iodide is the most important, have been given under the head of Iodine. By most practitioners the preparation under notice is preferred for producing the constitutional effects of iodine. When it is administered in large repeated doses it produces evidences of systemic infection, known as *iodism*. The most usual indication of its constitutional action is a pain over the brow, with coryza; in some cases a mild ptyalism, with fetor of the breath and slight swelling of the gums, is produced. In a number of cases it causes an eruption, sometimes simply of macula, but usually of acne. In unusual conditions of the system these skin affections may become very severe and ulcerations result. Thus, Dr. John O'Reilly, of New

York, reports several cases in which, after the use of this iodide, spots like purpura were produced, invading first the face and then the trunk and extremities. These became bullæ, sometimes an inch in diameter, filled with a purple liquid, and finally sphacelated spots ending in ulcers. Great constitutional disturbance coexisted, with swollen tongue, fetor, and salivation. Drs. Bumstead (*Am. Journ. Med. Sci.*, lxii. 101) and H. C. Wood have seen similar cases. When it is given in a too concentrated form, its local irritant properties assert themselves, and severe gastro-intestinal irritation or inflammation may result. The amount of iodine which the individual will bear varies, but in those who have not been gradually accustomed to its use the power of resisting very large doses is strong evidence of a syphilitic infection. In *periosteal nodes*, *specific rheumatism*, *diseases of the nervous system* or *large viscera*, and in other forms of advanced *secondary* or *tertiary syphilis*, potassium iodide acts as a specific, but must be given in very large doses and continuously for months or even years. It is when the symptoms are not very active, or when evidences of cachexia forbid mercurials, that it is especially indicated. In 1843, MM. Guillot and Melsens gave potassium iodide with advantage in doses of from a drachm to a drachm and a half daily, in *mercurial tremors* and *lead poisoning*. In a memoir published in 1849, M. Melsens gives a full account of his experiments with it as a remedy for the affections caused by mercury and lead. He effected a number of cures of *mercurial tremors* and *lead palsy;* and during the progress of the cure these metals were found in the urine. The value of potassium iodide in various chronic metallic poisonings is now established, and there can be little doubt as to the correctness of the theory of M. Melsens, namely, that potassium iodide forms with insoluble metallic compounds in the tissues soluble double salts, which are taken up by the blood and eliminated by the emunctories.* Potassium iodide sometimes produces ptyalism, but this ptyalism, when directly caused by the iodide, is never severe. Occasionally, however, during the taking of the iodide, furious ptyalism will occur, which is the result, as was first shown by Melsens, of the liberation from the tissues of mercury which had been previously taken, and which was enabled by being dissolved to produce constitutional effects. As this ptyalism may come on in persons who have not taken mercury for months, or perhaps for years, it would appear that that metal can long lie fixed and insoluble in the system, and finally, when liberated, produce serious constitutional symptoms. A prolonged mercurial treatment should always be followed by a course with potassium iodide. Dr. G. W. Balfour, of Edinburgh, published several cases of *aneurism of the aorta* in which potassium iodide was given in the dose of thirty grains twice or thrice daily with apparently great advantage, the symptoms of the disease having not only been greatly relieved, but in some instances having entirely disappeared. (*Edin. Med. Journ.*, July, 1868, p. 33; also April, 1871, p. 935.) The results probably were due to the aneurisms being of syphilitic origin. For the *softening of inflammatory deposits*, and for the *removal of exudations* not of syphilitic nature, potassium iodide is one of the most reliable remedies that we have. Hence it is much used in *chronic pleurisies*. In *chronic disease of the pulmonic parenchyma*, especially when tubercular, the exhibition of potassium iodide frequently has a pronounced effect in hastening softening and ulceration. Potassium iodide has been used internally by Dr. A. Beaufort with much supposed advantage for a local effect. Being largely secreted with the tears, and to a certain extent with the uterine fluids, he gives it with a view to its effects on the passages with which it thus comes in contact. In this way he explains the very good effects he has experienced from it in *chronic inflammation of the lachrymal passages*, and in *chronic metritis* with copious leucorrhœa. (*B. and F. Med.-Chir. Rev.*, Oct. 1868, p. 517.)

The dose of potassium iodide is from two to ten grains or more (0·13–0·65 Gm.), three times a day, given in dilute solution. In syphilitic cases, two, four, and even six drachms (7·8–15·5–23·3 Gm.) may be given daily with excellent results. When it is given in large amounts, care should be exercised to secure free dilution, and the best method of administration is in solution in milk. The compound syrup of sarsaparilla will in a measure disguise its taste.

Potassium iodide passes quickly into the urine, in which it may be detected by first adding to the cold secretion a portion of starch, and then a few drops of nitric acid, when a blue color will be produced. It has been detected in six minutes after having been swallowed. According to Schottin, it passes slowly into the sweat. Taken in half-drachm doses daily, it did not appear in that secretion until five days had elapsed.

Potassium iodide is employed as an external application in the form of ointment, either alone or mixed with iodine. (See *Unguentum Potassii Iodidi* and *Unguentum Iodi.*)

* See the Memoir of M. Melsens, translated by Dr. Budd, of Bristol, England, in the *Brit. and For. Med.-Chir. Rev.*, Am. ed., for Jan. 1853, p. 157; also a paper by Dr. J. W. Corson, in the *N. Y. Journ. of Med.* for Sept. 1853.

POTASSII NITRAS. U. S., Br. Potassium Nitrate. [Saltpetre.]

KNO_3; 100·92. (PŌ-TĂS'SI-Ī NĪ'TRĂS.) KNO_3; 101.

"Potassium Nitrate, KNO_3, may be obtained by purifying crude nitre, or by the interaction of sodium nitrate and potassium chloride." *Br.*

Kali Nitricum, *P. G.;* Nitrum Depuratum, Sal Petræ, s. Nitri, Nitras Potassicus, s. Kalicus: Nitrate of Potash, Nitre, Saltpetre; Nitrate de Potasse, Azotate de Potasse (Nitre prismatique), Salpêtre, *Fr.;* Salpetersaures Kali, Salpeter, Kalisalpeter, *G., Dutch, Dan., Sw.;* Nitro, *It., Sp., Port.*

Nitre, or saltpetre, is both a natural and an artificial product. It occurs in many countries, existing in the soil, on which it forms a saline efflorescence, in the fissures of calcareous rocks, and in caves. It has been found in different parts of Europe, in Egypt, and in Chili; but the country in which it is most abundantly produced is India, whence the principal part is furnished for the demands of commerce. In the United States it is found, for the most part, in caverns situated in limestone rock, called saltpetre caves, where it is associated with calcium nitrate. The earths contained in them are lixiviated, and yield, according to their richness, from one to ten pounds of crude nitre to the bushel. These caves are particularly numerous in Kentucky, and furnished a large proportion of the nitre consumed in the United States during the last war with England. According to Mr. E. S. Wayne, of Cincinnati, nitre earth exists near Nashville, Tenn., which yields 15 per cent. of nitre, and is said to be sufficiently abundant to supply the demand of the United States. In Bradford County, Pa., a solid, uncrystalline deposit of very pure nitre exists in a sandstone rock. (*Prof. W. H. Ellet.*) "A mountain" of the salt is said to have been discovered by Dr. Harrison among the Rocky Mountains, "six miles N.E. of Crystal Peak." (*A. J. P.*, 1866, p. 87.) Nitre exists also in the vegetable kingdom, having been found in tobacco, borage, bugloss, parietaria, hemlock, and the sunflower. The artificial sources of nitre are certain mixtures of animal and vegetable substances with wood-ashes and calcareous matter, called nitre-beds, and certain materials impregnated with saltpetre, consisting principally of plaster rubbish, derived from the demolition of old buildings. The ashes of tobacco-stems, consisting almost exclusively of potassium carbonate and chloride, have been proposed by M. Commaille as an artificial source of nitre, by adding them to the ordinary nitre-beds. (*Journ. de Pharm.*, Fév. 1856.)

Preparation from its Natural Sources. In India the saline earth, which contains about seven parts of nitre in a thousand, is lixiviated in large mud filters lined with stiff clay, and furnished with false bottoms of bamboo, covered with grass mats, on which wood-ashes are laid. The filters being then filled with the saline earth, water is added, and the solution filters through the wood-ashes, with the effect of converting the calcium nitrate present, amounting to nearly 1 per cent., into potassium nitrate. The solution obtained is evaporated in earthen pots, filtered, and set aside to crystallize. The impure nitre thus obtained contains from 45 to 70 per cent. of the pure salt. It is redissolved and crystallized, and thrown into commerce under the name of crude saltpetre. Besides the nitre obtained in India by the filtration of the soil deposited during the overflow of the Ganges, it appears, from the report of Dr. J. W. Palmer, that much of the crude salt is procured, in the northwestern provinces of Hindostan, from the saline incrustations formed in and around the mud walls surrounding the dwellings of the natives. The scrapings from these sources are lixiviated, and the impure solution allowed to evaporate in shallow pans exposed to the sun. The impure nitre extracted from the earthy matters crystallizes out; while from 1 to 9 per cent. of common salt remains in the mother-liquor, and is recovered by evaporation. (*A. J. P.*, 1868, 436.) *Juar*, a plant used in India as fodder, contains in its stems during dry seasons a large quantity of potassium nitrate (17 per cent.); when in this condition it is poisonous to animals. (*P. J. Tr.*, 1896, 380.)

Within recent years nitre has been largely manufactured from the native potassium chloride of Stassfurt and the native sodium nitrate of Chili, two cheap and abundant crude materials, which by their reaction yield potassium nitrate. For this purpose equal molecular quantities of the two salts are dissolved in water with the aid of heat until the specific gravity of the liquor reaches 1·5. Sodium chloride, being much less soluble in hot water, is precipitated, and the clear solution on cooling and on agitation deposits the saltpetre as a fine powder. This so-called "conversion saltpetre," as manufactured by Vorster & Grüneberg, of Kalk, Germany, and exhibited at the Chicago Exposition, is said to be 99·9 per cent. pure nitrate.

Artificial Preparation. The plan of making saltpetre in artificial nitre-beds is principally practised in Germany; while the method of obtaining it from old plaster rubbish is followed in France. *Artificial nitre-beds* are formed of animal and vegetable remains, together with ashes and calcareous earth, which are mixed up with a portion of loose soil and placed

under sheds, to shelter the mixture from the rain, while the sides are left open, to admit the free access of air. The mixture is disposed in little ranges or heaps, which are frequently turned over with a spade, and sprinkled with urine, as a substance containing a large quantity of nitrogen. At the end of two or three years the nitrogen is converted into nitric acid, and this, by uniting with the potassa existing in the vegetable remains, forms nitre. When the contents of the bed contain about four ounces of the salt for every cubic foot of the materials, they are deemed fit to be lixiviated. The lixiviation is performed with boiling water, which is repeatedly thrown upon fresh portions of the mass, until the solution obtained is sufficiently strong. The lixivium is of a brown color, and contains chiefly potassium nitrate, but at the same time more or less of calcium and magnesium nitrates and of common salt. The earthy nitrates are then decomposed by a solution from wood-ashes, the potassa of which converts them into nitre and precipitates the earths. The solution being further evaporated, the common salt rises to the surface as a scum, and is removed. The solution is then allowed to cool, and the nitrate crystallizes in dirty-white crystals, called crude nitre. Calcium nitrate may be converted into nitre by adding it to a solution of potassium sulphate. Calcium sulphate is precipitated, and potassium nitrate remains in solution.

When obtained from old plaster rubbish, the material is reduced to powder and lixiviated, in order to exhaust it of everything soluble. The solution is found to contain potassium and calcium nitrates and common salt, and is treated with wood-ashes, which convert the calcium nitrate into potassium nitrate, with precipitation of the earth as a carbonate. The liquor is separated from the precipitate and concentrated by heat; and the common salt, as it rises to the surface, is skimmed off. When the solution is so strong as to mark 45° of Baumé's hydrometer, it is allowed to cool and crystallize; and the crystals form the crude nitre of this process. The salt obtained in this way generally contains from 85 to 88 per cent. of pure nitre, the remainder being made up of sodium chloride and certain deliquescent salts. The details of this process, as formerly practised in Paris, are given by Thénard.

Theory of Nitrification. The continuous formation of nitre in nitre earths and in artificial nitre-beds results from the oxidation of the nitrogen of ammonia, thus generating nitric acid, the formation of which is facilitated by the presence of alkaline and earthy bases, with which the acid unites, but in reality depends upon the presence of nitrifying micro-organisms (*Bacillus nitrificans*), so that nitrification is not strictly an oxidation process, as was at one time supposed. The ammonia is derived, for the most part, from the organic remains in the nitre earths, and from the animal matter which is an essential ingredient in the artificial mixtures. According to Schoenbein, whose statement has been confirmed by Goppelsröder, the formation of the nitric acid is always preceded by that of nitrous acid.

Purification. Potassium nitrate, as first obtained, either from natural or from artificial sources, is called in commerce crude saltpetre, and requires to be purified before it can be used in medicine or in most of the arts. The process, which is founded principally on the fact that nitre is more soluble than common salt in hot water, is conducted in France as follows. Thirty parts of saltpetre are boiled with six parts of water, and the portion which remains undissolved or is deposited, consisting of common salt, is carefully removed. As the ebullition proceeds, a little water is added from time to time, to hold the nitre in solution. When common salt ceases to be separated, the solution is clarified with glue, and more water is added, at intervals, until the whole, including that previously added, amounts to ten parts. The clear solution is now transferred to large, shallow copper coolers, where it is agitated with wooden instruments to hasten the cooling and to cause the nitre to crystallize in small grains. The purification is completed by washing the salt with water, or a saturated solution of nitre, in a kind of wooden hopper with holes in the bottom stopped with pegs. The liquid employed is allowed to remain in contact with the nitre for several hours, after which it is permitted to drain off by taking out the pegs. The salt is now dried, and takes the name of purified nitre.

In Sweden the process of purification is conducted in a different manner. The solution of the crude nitre is boiled until a saline crust (common salt) forms on its surface, and until it is so far concentrated that a small portion of it crystallizes upon cooling. The crust being removed, the solution is filtered, and diluted with 1-48th of water, with a view to retain in solution the common salt, which, being somewhat less soluble in cold than in boiling water, would otherwise be in part precipitated on refrigeration. This solution is now allowed to cool, and, at the moment the crystals begin to form, is stirred constantly, to cause the salt to crystallize in small grains. The granular salt is then washed after the French method, as above described, dried, and, being fused, is cast in sheet-iron moulds so as to form masses each weigh-

ing from ten to twenty pounds. The preparation of nitre in this manner by fusion is, according to Berzelius, attended with several advantages, such as occupying less space, losing nothing by waste in transportation, and presenting, in this state, an obvious index of its quality. This index is the character of its fracture. When the salt is perfectly pure, the fracture is radiated, the radii being generally large. The presence of 1-80th of common salt renders the radii smaller; that of 1-40th, or of a larger quantity, produces a zone in the substance of the mass devoid of the radiated structure, or causes this structure to disappear entirely. On the other hand, the melting of the salt has the disadvantage of converting it in part into nitrite if the heat be too high, and of rendering it difficult to pulverize.

Commercial History. Nitre is sometimes received in this country from Calcutta packed in grass-cloth bags containing from one hundred and fifty to one hundred and seventy-five pounds. Its quality varies considerably. That which comes in dirty-yellow crystals is called *crude saltpetre;* while the finer lots, in small, comparatively clear crystals, approaching to white, are called *East India refined.* Very little crude saltpetre is at present obtained from native sources in the United States. The *refined saltpetre* is almost exclusively prepared by our own chemists. The importations of crude potassium nitrate are at present about one-fifteenth of the amount of crude sodium nitrate imported. The amount for the year 1896 was 20,085,327 lbs., and for 1897, 16,276,352 lbs. For an account of what is incorrectly called *South American saltpetre*, see *Sodii Nitras.*

Properties. Potassium nitrate occurs as "colorless, transparent, six-sided, rhombic prisms, or a crystalline powder, odorless, and having a cooling, saline and pungent taste. Permanent in the air. Soluble in 3·8 parts of water at 15° C. (59° F.), and in 0·4 part of boiling water; very sparingly soluble in alcohol. When heated to 353° C. (667·4° F.), the salt melts. At a higher temperature it is decomposed, giving off oxygen at first, and then some of its nitrogen, leaving a residue of potassium nitrate, nitrite, and oxide. Thrown upon red-hot coals, the salt deflagrates. The aqueous solution is neutral to litmus paper. With sodium bitartrate test-solution the aqueous solution (1 in 20) yields a white, crystalline precipitate; with sodium cobaltic nitrite test-solution, a yellow precipitate. If a small crystal of ferrous sulphate be dissolved in the aqueous solution (1 in 20), and then concentrated sulphuric acid be poured in, so as to form a separate layer, a dark-brown color will appear at the line of contact. If a drop of diphenylamine test-solution be mixed with the aqueous solution and concentrated sulphuric acid be poured in as in the preceding test, a deep-blue color will appear at the line of contact. The aqueous solution (1 in 20) should remain unaffected by the addition of a few drops of potassium ferrocyanide test-solution (absence of *iron*); or of barium chloride test-solution (*sulphate*); or of silver nitrate test-solution (*chloride*); or of ammonium carbonate test-solution, ammonium oxalate test-solution, or ammonium sulphide test-solution (absence of *calcium*, *zinc*, etc.); or by the addition of an equal volume of hydrogen sulphide test-solution, either before or after acidulation with hydrochloric acid (absence of *arsenic*, *lead*, *copper*, etc.). If to 5 C.c. of the aqueous solution of the salt 1 C.c. of chlorine water and a few drops of starch test-solution be added, no blue color should appear (absence of *iodine*). No yellow color should appear when 1 C.c. of pure, concentrated sulphuric acid is added to 0·1 Gm. of the dry salt (absence of *chlorate*)." *U. S.* "In white crystalline masses or fragments of striated six-sided rhombic prisms, colorless, having a cool saline taste. It is soluble in 4 parts of cold and half its weight of boiling *water*." *Br.* It is devoid of water of crystallization, but is apt to contain a portion of liquid mechanically lodged within the substance of the crystals. This is particularly the case with the *large* crystals, and, according to Berzelius, is a source of impurity, as the liquid in question is a portion of the mother-water in which they were formed. It is on this account that Berzelius recommends that the solution of the purified salt should be stirred during crystallization, so as to cause it to shoot into *small* crystals. The fused mass, when cast in moulds, or formed into little circular cakes, constitutes that form of nitre found in commerce under the name of *crystal mineral* or *sal prunelle.** If the heat is increased, the salt is decomposed, evolves pure oxygen, and is reduced to the state of nitrite, which, in powder, emits orange-colored fumes of hyponitric acid, and nitrous oxide on the addition of sulphuric acid. Upon a further continuance of the heat, the nitrous acid itself is decomposed, and a large additional quantity of oxygen is evolved, contaminated, however, with more or less

* *Sal prunelle*, as directed to be made in the French Codex of 1837, is a mixture of potassium nitrate and sulphate. It is prepared by fusing nitre in a Hessian crucible, adding 1-128th part of sulphur, and pouring out the product on a smooth marble slab, where it is allowed to congeal. The sulphur immediately takes fire, and, by combining with oxygen from a part of the nitric acid of the nitre, becomes sulphuric acid, which then unites with a small portion of potassa, to form potassium sulphate.

nitrogen. On account of the large proportion of oxygen which it contains, nitre increases the combustion of many substances in a remarkable degree. When thrown on burning coals, it deflagrates with bright scintillations. In the reaction of nitre with charcoal, carbonic acid is produced, and never carbonic oxide; and the nitric acid is variously decomposed into nitrous oxide, nitrogen dioxide, or nitrogen, according to the proportion of the charcoal and to the heat employed. (*A. Vogel, Jr.*) Nitre may be readily recognized by its effect in increasing the combustion of live coals when thrown upon them, and by evolving white or reddish vapors on the addition of sulphuric acid. If the residue in this case weighs less than the amount calculated for potassium sulphate, part of it is probably sodium sulphate, and the nitre tested may be assumed to have contained sodium nitrate. The most usual impurity is common salt, which is seldom entirely absent, and which injures it for the manufacture of gunpowder.* The refined or purified saltpetre of commerce is sufficiently pure for medicinal use. Potassium nitrate is composed of one atom of potassium in combination with one nitric acid group, which latter is monobasic. M. Violette, on mixing a few grains each of sodium nitrate and sodium acetate, previously fused, noticed a few gaseous bubbles given off, and at the same time a violent explosion took place, which scattered the vial in fragments over his laboratory. On heating a mixture of a grain each of potassium nitrate and sodium acetate, the mixture remained fluid at 300° C. (572° F.) and perfectly quiet; but when the temperature was increased to about 350° C. (662° F.) a slight ebullition was noticed, instantly followed by a loud explosion, with light and smoke like exploded gunpowder. (*A. J. P.*, 1873, p. 128.)

Medical Properties. Potassium nitrate, when in sufficient concentration, acts upon a raw surface or a mucous membrane as a violent irritant, and taken internally in concentrated form produces violent burning pain, vomiting, purging, and other evidences of gastro-enteritis, which may end in collapse and death. Inflammation and ulceration of the mucous membrane are commonly found at the autopsies. In its general action potassium nitrate shares the sedative influence of the potassium salts in general, and was at one time much used as a diuretic and diaphoretic, but is at present very rarely employed, except as a local remedy. It is, however, sometimes prescribed with tartar emetic and calomel, forming the so-called *nitrous powder*, which promotes most of the secretions, particularly those of the liver and skin, and is sometimes advantageous in lessening and modifying febrile excitement. The formula usually preferred is eight or ten grains (0·52–0·65 Gm.) of nitre, the eighth of a grain (0·008 Gm.) of tartar emetic, and from the fourth to the half of a grain (0·016–0·03 Gm.) of calomel, exhibited every two or three hours.

At one time nitre was used in very large doses in acute *rheumatism*, but the practice has passed out of vogue. It is essential always to give the remedy very freely diluted, if at all, and thus avoid its irritant influence upon the gastro-intestinal tract. An ounce taken in a little water has produced death, whilst a dilute solution of several ounces has been recovered from.

As a local remedy the nitrate is similar in its action to potassium chlorate, but it is probably less efficient, and certainly has been largely replaced by the chlorate in the treatment of *stomatitis*, *angina*, and local inflammations. In *asthma*, nitrous fumigation is often useful, performed by inhaling the fumes from burning touch-paper, prepared by dipping blotting-paper in a saturated solution of nitre and afterwards drying it. M. Vohl has examined the vapor resulting from the burning of paper thus impregnated, and found it to consist of carbonic acid and oxide, cyanogen, ammonia, nitrogen, aqueous vapor, and potassium carbonate and nitrite, and he ascribes the beneficial results of its inhalation to the ammonia and potassium nitrite. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 155, 1866.)

In pharmacy nitre was formerly employed to form crocus of antimony, to procure nitric acid, and sometimes in the preparation of sweet spirit of nitre. In the laboratory it is used to make black and white flux, as an oxidizing agent, and to yield oxygen at a red heat. It was formerly employed in the production of aqua fortis (common nitric acid) and in the manufacture of sulphuric acid, and is yet employed in the fabrication of gunpowder. The Br. Pharmacopœia 1885 used it in the purification of bismuth.

POTASSII PERMANGANAS. U. S., Br. Potassium Permanganate.

$KMnO_4$; 157·67. (PŌ-TĂS'SĬ-Ī PĔR-MĂN'GĂ-NĂS.) **$KMnO_4$; 157.**

"Potassium Permanganate should be kept in glass-stoppered bottles, protected from light, and should not be brought in contact with organic or readily oxidizable substances." *U. S.*

* For a method of estimating the nature and amount of the various impurities in commercial saltpetre, see M. Persoz, *A. J. P.*, 1861, 543.

"Potassium Permanganate, $K_2Mn_2O_8$, may be obtained by the interaction of potassium chlorate, potassium hydroxide, and manganese dioxide." *Br.*

Kali Hypermanganicum Crystallisatum, *P. G.;* Hypermanganas Potassicus, s. Kalicus; Permanganate of Potash; Permanganate de Potasse, *Fr.;* Uebermangansaures Kali, *G.*

The British Pharmacopœia 1885 furnished a detailed process for this salt, as follows:

"Take of Caustic Potash *five ounces* [avoirdupois]; Black Oxide of Manganese, in fine powder, *four ounces* [av.]; Chlorate of Potassium *three ounces and a half* [av.]; Distilled Water *two pints and a half* [Imperial measure]; Carbonic Acid *a sufficiency.* Reduce the Chlorate of Potassium to fine powder, and mix it with the Oxide of Manganese; put the mixture into a porcelain basin, and add to it the Caustic Potash, previously dissolved in four [fluid]ounces of the Water. Evaporate to dryness on a sand-bath, stirring diligently to prevent spurting. Pulverize the residual mass, place the powder in a covered crucible, exposing it to a dull red heat for an hour, or until it has assumed a semi-fused condition. Let it cool, pulverize it, and boil with a pint and a half [Imp. meas.] of the Water. Let the insoluble matter subside, decant the fluid, boil again with half a pint [Imp. meas.] of the Water, again decant, saturate the united liquors with Carbonic Acid, and evaporate till a pellicle forms. Set aside to cool and crystallize. Drain the crystalline mass, boil it in six [fluid]ounces of the Water, and strain through a funnel, the throat of which is lightly obstructed by a little asbestos. Let the fluid cool and crystallize, drain the crystals, and dry them by placing them under a bell-jar over a vessel containing sulphuric acid."

By this process potassium chlorate yields oxygen to manganese dioxide, converting it into manganic acid, which unites with the potassa to form the manganate, potassium chloride being formed at the same time; the reaction being $3MnO_2 + 6KOH + KClO_3 = 3K_2MnO_4 + KCl + 3H_2O$. When this solution is boiled, the potassium manganate reacts with the water and yields potassium permanganate, according to the reaction $3K_2MnO_4 + 3H_2O = K_2Mn_2O_8 + H_2MnO_3 + 4KOH$, the hydrated peroxide separating out. Hence, when exhausted by water, the solution requires the saturation of the free alkali with carbonic acid, as stated in the process above. At best, the product is small and uncertain in amounts. A cheaper commercial preparation, consisting of a mixture more or less pure of sodium manganate and permanganate, is manufactured on a large scale for disinfecting purposes. It is obtained by mixing the caustic soda obtained from 1500 kilogrammes of soda-ash with 350 kilogrammes of finely divided manganese dioxide in a flat vessel, and heating this mixture for forty-eight hours to dull redness. The product is then lixiviated with water, and the solution either boiled down to the requisite degree of strength or evaporated to dryness. Potassium permanganate has also been made by the electrolysis of the manganate, the products being permanganate, potassium hydrate, and hydrogen. A still more interesting result of electrolysis is the production of potassium permanganate by the electrolysis of caustic potash, in which the negative electrode is of porous copper oxide and the positive electrode a piece of manganese or ferro-manganese held immersed by a loop of platinum wire.

Properties. It is officially described as in "slender, monoclinic prisms, of a dark-purple color, almost opaque by transmitted and of a blue, metallic lustre by reflected light, odorless, and having a taste at first sweet, but afterwards disagreeable and astringent. Permanent in the air. Soluble in 16 parts of water at 15° C. (59° F.), and in 3 parts of boiling water. In contact with alcohol it is decomposed. When heated, the salt decrepitates, and at 240° C. (464° F.) it decomposes, yielding oxygen, potassium manganate, and manganese dioxide. The aqueous solution of the salt is of a deep violet-red color when concentrated, and of a rose color when much diluted, and this color is discharged by hydrogen sulphide, ferrous sulphate, oxalic acid, alcohol, and many other readily oxidizable substances, especially if the solution be first rendered acid by sulphuric acid. The solution is neutral to litmus paper. If 0·5 Gm. of the salt be boiled with 10 C.c. of ammonia water and 10 C.c. of water (or with 20 C.c. of water and 4 C.c. of alcohol) until it is completely decomposed, and the liquid then filtered, the clear, colorless filtrate will serve for the following tests: If to 5 C.c. of the filtrate, acidulated with nitric acid, barium chloride test-solution be added, not more than very slight turbidity should be produced (limit of *sulphate*). In another portion of 5 C.c., acidulated with nitric acid, silver nitrate test-solution should produce no precipitate or cloudiness (absence of *chloride*). If to another portion of 5 C.c. of the filtrate 1 drop of diphenylamine test-solution be added, and then 1 C.c. of pure concentrated sulphuric acid be poured in, so as to form a layer beneath, no blue color should appear at the line of contact (absence of *nitrate* or *chlorate*). If 0·1 Gm. of the salt be dissolved in 10 C.c. of boiling distilled water, and 1 C.c. of sulphuric acid be cautiously added, the solution should require for complete decoloration not less than 31·3 C.c.

of oxalic acid decinormal volumetric solution (corresponding to at least 98·7 per cent. of the pure salt)." *U. S.* "Dark purple slender prismatic iridescent crystals, with a sweet astringent taste, soluble in 20 parts of cold *water*, without action on *litmus*. The crystals heated to redness decrepitate, evolve oxygen, and leave a black residue from which *water* extracts potassium hydroxide, the resulting solution affording the reactions characteristic of potassium. It should yield no characteristic reaction with the tests for lead, arsenium, iron, aluminium, calcium, magnesium, sodium, ammonium, carbonates, chlorides, or sulphates. Each gramme dissolved in *water*, and acidulated with 5 cubic centimetres of *diluted sulphuric acid*, should require for complete decolorization 31·2 cubic centimetres of an aqueous solution containing 62·58 grammes of pure crystallized *oxalic acid* per litre." *Br.*

If the solution be evaporated to dryness, the salt has the form of an intensely black powder. If suddenly heated, the crystals detonate, evolving oxygen, and leaving a black residue, which yields potassa to water, recognized by its alkaline reaction, and by giving, when acidulated with hydrochloric acid, a yellow precipitate with platinic chloride. Moderately heated, they are partially volatilized, giving out violet vapors of a disagreeable metallic odor. (*A. J. P.*, Sept. 1862, p. 409.) The salt, in consequence of the facility with which it parts with oxygen, is one of the most powerful oxidizing agents known. It causes the combustion of certain inflammable bodies, imparts oxygen to almost all organic substances, and in chemistry is employed to bring various compounds to a higher degree of oxidation. The readiness with which it yields oxygen in the nascent state is sufficient to account for its oxidizing power. It may be kept indefinitely if pure, and carefully secured from contact with organic substances, or other decomposing agents; but in fact, in consequence of the almost universal presence of organic matter in the air, it is generally partially decomposed, and, when dissolved, leaves a slight residue of hydrated manganese dioxide. In reference to the metals, mercury is quickly oxidized at the expense of the salt, a mixture of mercurous oxide and manganese oxide being deposited as a brown powder, and caustic potassa remaining in solution. Zinc remains unchanged indefinitely in a solution of the permanganate, silver is little affected, and copper not at all, even at 100° C. (212° F.). (Giles, *Journ. de Pharm. et de Chim.*, Mai, 1868, p. 397.)

H. B. Condy introduced (*Journ. Soc. Chem. Indus.*, 1885, p. 567) a permanganate disinfectant, which contains also aluminum sulphate, which is said to increase the oxidizing effect of the permanganic acid. He asserts that in this disinfectant solution all the available oxygen of the permanganic acid is utilized, whereas only 60 per cent. of this amount is utilized with the simple alkaline permanganate.
